To Emerson:

"There's a difference between knowing the path…, and walking the path."
(Morpheus)

About the Author

Scott Mueller is president of Mueller Technical Research, an international research and corporate training firm. Since 1982, MTR has specialized in the industry's most in-depth, accurate, and effective corporate PC hardware and technical training seminars, maintaining a client list that includes Fortune 500 companies, the U.S. and foreign governments, major software and hardware corporations, as well as PC enthusiasts and entrepreneurs. His seminars have been presented to several thousands of PC support professionals throughout the world.

Scott has developed and presented training courses in all areas of PC hardware and software. He is an expert in PC hardware, operating systems, and data-recovery techniques. He currently spends about 20–25 weeks per year on the road teaching his seminars at several corporate clients. For more information about a custom PC hardware or data-recovery training seminar for your organization, contact Lynn at

Mueller Technical Research
21 Spring Lane
Barrington Hills, IL 60010-9009
(847) 854-6794
(847) 854-6795 Fax
Internet: `scottmueller@compuserve.com`
Web: `http://www.upgradingandrepairingpcs.com`
`http://www.m-tr.com`

Scott has many popular books, articles, and course materials to his credit, including *Upgrading and Repairing PCs*, which has sold more than 2 million copies, making it by far the most popular PC hardware book on the market today.

If you have suggestions for the next version of the book, or any comments about the book in general, send them to Scott via email at `scottmueller@compuserve.com` or visit `www.upgradingandrepairingpcs.com` and click the Ask Scott button.

When he is not working on PC-related books or on the road teaching seminars, Scott can usually be found in the garage working on several projects. This year he continues to work on his customized '99 Harley FLHRCI Road King Classic with a 95ci Twin-Cam motor (see you in Sturgis <g>), as well as a modified 1998 5.9L Grand Cherokee (imagine a hotrod SUV).

Contributors and Technical Editors

Mark Edward Soper is president of Select Systems and Associates, Inc., a technical writing and training organization.

Mark has taught computer troubleshooting and other technical subjects to thousands of students from Maine to Hawaii since 1992. He is an A+ Certified hardware technician and a Microsoft Certified Professional. He has been writing technical documents since the mid-1980s and has contributed to several other Que books, including *Upgrading and Repairing PCs, 11th and 12th Editions*; *Upgrading and Repairing Networks, Second Edition*; *and Special Edition Using Microsoft Windows Millennium Edition*. Mark coauthored both the first and second editions of *Upgrading and Repairing PCs, Technician's Portable Reference* and *Upgrading and Repairing PCs: A+ Study Certification Guide, Second Edition*. He is the author of *The Complete Idiot's Guide to High-Speed Internet Connections* and coauthor of *TechTV's Upgrading Your PC*.

Mark has been writing for major computer magazines since 1990, with more than 125 articles in publications such as *SmartComputing*, *PCNovice*, *PCNovice Guides*, and the *PCNovice Learning Series*. His early work was published in *WordPerfect Magazine*, *The WordPerfectionist*, and *PCToday*. Many of Mark's articles are available in back issues or electronically via the World Wide Web at `www.smartcomputing.com`. Select Systems maintains a subject index of all Mark's articles at `http://www.selectsystems.com`.

Mark welcomes comments at `mesoper@selectsystems.com`.

Mark Reddin is president of Trinity Microsystems, Inc., a computer reseller and repair center in Indiana. He is a Microsoft Certified Systems Engineer (MCSE) and A+ Certified PC technician who has enjoyed using computers, as well as breaking and fixing them, since the days of the early Commodore and Atari machines. Mark still enjoys being involved with computers and networks at a hands-on level and can often be found in the trenches, configuring hardware and running cables. He has been involved with several Que publications, providing technical verification as well as development. You can reach him through the contacts page at `www.trinitymicrosystems.com`.

Jeff Sloan is the Dimension OEM BIOS development manager for Dell Computers. Prior to Dell, he worked at IBM PC Company for 15 years, the last 8 of which were spent in PS/2 BIOS development and the Problem Determination SWAT team. He has a bachelor of science degree in computer science from the University of Pittsburgh, 1979, and is currently working on a master of science degree in software engineering at Southwest Texas State. Jeff has tech edited numerous Que books.

Kent Easley is an assistant professor of computer information systems at Howard College in Big Spring, Texas. He teaches introductory computer science, networking, and programming. He is a Microsoft Certified Professional and supervises the Microsoft Authorized Academic Training Program (AATP) at Howard College. He has experience as a network administrator and as a systems librarian. Kent has tech edited numerous Que books. He can be reached by email at `keasley@hc.cc.tx.us`.

Karen Weinstein is an independent computer consultant living in North Potomac, Maryland. She has had more than a decade of experience in PC sales and support. Karen has a B.S. in business administration from the University of Maryland.

Acknowledgments

The 13th Edition continues the long tradition of making this the most accurate, in-depth, and up-to-date book of its kind on the market. Plus, by the title you can tell I'm not superstitious. <g> This new edition is the product of a great deal of additional research and development over the previous editions. Several people have helped me with both the research and production of this book. I would like to thank the following people:

First, a very special thanks to my wife and partner, Lynn. This book continues to be an incredible burden on both our business and family life, and apparently I can be slightly incorrigible after staying up all night writing. Who would've guessed?

I suppose it doesn't help that most of my all-night writing raves are fueled by a variety of possibly less than nutritious (but very tasty and loaded with temporary energy) food and beverage. In particular, this edition was fueled mainly by Starbucks coffee (by the 2lb. bag of course), Coke Classic (no Pepsi allowed—gotta have the burn!), and literally cases of Trolli Brite Crawler Eggs and Pearson's Salted NutRolls. Why, that covers the three major workaholic nerd/geek food groups right there: caffeine, sugar, and salt!

Thanks to Lisa Carlson of Mueller Technical Research for helping with product research and office management. She has fantastic organizational skills that have been a tremendous help in managing all of the information that comes into and goes out of this office.

I must give a special thanks to Rick Kughen at Que. Rick is the number one person responsible for taking what I submit and turning it into a finished book. His office is like a shrine to *Upgrading and Repairing PCs*, sporting a complete collection of every single edition since the first, along with enough PC parts, peripherals, and components to build several systems. His attention to detail is amazing, and he genuinely cares about both the book and my readers, often going far above and beyond the call of duty when it comes to customer service and support. Rick is also largely responsible for the excellent content we've included on the CD, especially the new video clips we shot for this edition. Rick, thanks so much for your dedication and hard work!

I'd also like to thank Todd Brakke as well as the numerous other editors, illustrators, designers, and technicians at Que who work so hard to complete the finished product and get this book out the door! They are a wonderful team that produces clearly the best computer books on the market. I am happy and proud to be associated with all the people at Que.

I would also like to say thanks to Mark Soper, who added expertise in areas that I might tend to neglect. Also thanks to all the technical editors who checked my work and questioned me at every turn, helping me to ensure the highest level of technical accuracy and coverage.

Thanks to all the readers who have emailed me with suggestions concerning this book; I welcome all your comments. A special thanks to Paul Reid, who has helped orchestrate online conferences on the Compuserve PC Hardware forum and who has been a long-time reader.

Finally, I would like to thank the thousands of people who have attended my seminars; you might not realize how much I learn from each of you and all your questions! Thanks also to those of you on the Internet and CompuServe forums with both questions and answers, from which I have also learned a great deal.

Tell Us What You Think!

As the reader of this book, *you* are our most important critic and commentator. We value your opinion and want to know what we're doing right, what we could do better, what areas you'd like to see us publish in, and any other words of wisdom you're willing to pass our way.

As an associate publisher for Que, I welcome your comments. You can fax, email, or write me directly to let me know what you did or didn't like about this book—as well as what we can do to make our books stronger.

Scott Mueller welcomes your technical questions. The best way to reach him with a question is via the "Ask Scott" section on the `www.upgradingandrepairingpcs.com` *Web site. Although he sometimes falls behind in getting to all the questions directly, he does his best to answer them all. Be sure to check the Frequently Asked Questions listed on the Web site before asking your question, as Scott might have already posted an answer.*

When you write, please be sure to include this book's title and author as well as your name and phone or fax number. I will carefully review your comments and share them with the author and editors who worked on the book.

Editor's Note

Welcome to *Upgrading and Repairing PCs, 13th Edition*. The book you are holding isn't just another PC hardware book. It isn't a technical manual suited only for geeks with screwdrivers. This book is a way of life. Ask the buyers before you who have purchased more than two million copies of this book in its storied history. These readers have made this book far and away the most popular PC hardware book ever written and one of the best-selling computer books of all time. Those millions of readers will tell you that this book changed their lives, launched careers, resurrected dead PCs, and helped them achieve personal computing nirvana.

If you are new to the phenomenon that is *Upgrading and Repairing PCs*, it might be news to you that you are holding an industry classic. If you are a longtime reader of Scott's opus, this book is an old friend to you. Thank you for making this book the runaway success that it has become.

For every industry expert using this book, there are probably 10 teachers, students, auto mechanics, accountants, physicians, lawyers, and sales clerks who rely on this book to troubleshoot and upgrade their PCs. You don't have to be a computer guru to understand the material provided here. So long as you are armed with a desire to learn what goes on under the hood of your PC, this book will be your guide. I am living proof of this. I spent my collegiate and early professional years conjugating verbs, diagramming sentences, and arguing the merits of Shakespeare. Prior to editing this book for the first time, I didn't know the business end of a screwdriver from a torque wrench and most certainly had never ventured inside my PC, where there lived a rat's nest of cables and, and *things*. I learned PC repair and upgrading from Scott. Today, I'm as at home inside a PC as I am fixing sentences ending in prepositions and clipping participles that dangle.

Scott has taught thousands of people, just like you, in his live corporate seminars. This book is an extension of those classes and is used by Scott every day as he travels the country teaching PC hardware upgrading and repair. Every word, illustration, and photo has been painstakingly shaped and molded to help you and your PC coexist in harmony. Whether you are a corporate IT manager charged with maintaining hundreds of workstations or a sales clerk who would like to put a little spring back into your PC's step, this book is for you.

In this edition, you'll find hundreds of pages of new material covering the Intel Itanium and Pentium 4 processors, as well as AMD's Athlon and Duron. You'll find coverage of CD and DVD technology that will literally bring tears to your eyes. If you are an owner of a newer Dell PC, you'll learn about some things lurking in your PC that could spell disaster if you attempt to upgrade the motherboard. Speaking of disasters, Scott also has included a special troubleshooting index that points you to the sections in this mammoth book that can help you when you're sweating bullets trying to repair your beloved PC. Scott knows it's a little tough to dig through a book this size when fire is licking from the case vents or your PC looks as though it might sprout legs, skitter off the desk, and make a wild grab for the fireplace poker. When you're in trouble, this index will be just the ticket.

The CD contains 90 minutes of all-new video that was shot in a professional-grade studio in the Spring 2001. This video shows you how to build a PC from the ground up. Along the way, Scott tells you how each component works, and which tools you will need to do the job right. If you aren't one of the lucky few who get to attend one of Scott's seminars, think of the video as your way of learning from him in person.

Take a few minutes in whatever bookstore you are reading this and compare this book to Scott's competition. Get a cup of coffee and have a seat in the aisle. Flip through this book and see whether you come to the same conclusion that millions of readers before you have come to: *This is the book that could change my life.*

I'm betting that you will.

Rick Kughen
Executive Editor
Que

Introduction

Welcome to *Upgrading and Repairing PCs, 13th Edition*. More than just a minor revision, this new edition contains hundreds pages of new material, not to mention extensive updates to existing material. The PC industry is moving faster than ever, and this book is the most accurate, complete, in-depth, and up-to-date book of its type on the market today.

This book is for people who want to upgrade, repair, maintain, and troubleshoot computers or for those enthusiasts who want to know more about PC hardware. This book covers the full range of PC-compatible systems from the oldest 8-bit machines to the latest in high-end 64-bit Gigahertz-plus speed PC-based workstations. If you need to know about everything from the original PC to the latest in PC technology on the market today, this book and the accompanying information-packed CD is definitely for you.

This book covers state-of-the-art hardware and accessories that make the most modern personal computers easier, faster, and more productive to use. Hardware coverage includes all the Intel and Intel-compatible processors through the latest Itanium and Pentium 4 models, the Pentium III/Celeron, AMD Athlon and Duron CPU chips; new cache and main memory technology, such as RDRAM and DDR SDRAM; PCI and AGP local bus technology; CD-ROM/DVD drives, including recordable types; tape drives; sound boards; PC-card and Cardbus devices for laptops; IDE/ATA and SCSI interface devices; larger and faster hard drives; and new video adapter and display capabilities.

The comprehensive coverage of the Intel-compatible personal computer in this book has consistently won acclaim since debuting as the first book of its kind on the market in 1988. Now with the release of this 13th Edition, *Upgrading and Repairing PCs* continues its role as not only the best-selling book of its type, but also the most comprehensive and complete reference on even the most modern systems—those based on cutting-edge hardware and software. This book examines PCs in depth, outlines the differences among them, and presents options for configuring each system.

Sections of this book provide detailed information about each internal component of a personal computer system, from the processor to the keyboard and video display. This book examines the options available in modern, high-performance PC configurations and how to use them to your advantage; it focuses on much of the hardware and software available today, and specifies the optimum configurations for achieving maximum benefit for the time and money you spend.

New in the 13th Edition

Many of you who are reading this have purchased one or more of the previous editions. Based on your letters, emails, and other correspondence, I know that as much as you value each new edition, you want to know what new information I'm bringing you. So, here is a short list of the major improvements to this edition:

- This book contains hundreds of pages of deep and balanced coverage of new processors from Intel and AMD, including the long-awaited Pentium 4 and 64-bit Itanium processors. No other PC book on the shelf provides comprehensive coverage of the bevy of processors available from AMD and Intel—and no other PC book explains just exactly what you're up against when matching motherboards and RAM to these processors.
- Cutting-edge coverage of the Pentium 4—Intel's long-awaited Pentium 4 processor hit the shelves in 2000. I steer you through what promises to be the biggest—and most demanding—processor upgrade since the world shifted from 486 processors to the Pentium.

- Own a Dell PC? Interested in not turning it into a charcoal briquette when installing a new power supply or motherboard? What you read here could prevent an untimely meltdown of your beloved PC!
- Interested in turning your PC into a hot rod game machine? Want to rule the Internet Unreal community with an iron fist? Read my coverage of audio, video, and Internet connectivity for the lowdown on supercharging your PC.
- Use the new troubleshooting index to track down pesky problems with everything from IRQ conflicts to audio quality. When your beloved PC is in trouble, head straight to this index for help—*fast*.
- Many new, high-quality technical illustrations. I've really pushed the quality of the illustrations of this book. These new and revised illustrations provide more technical detail, helping you understand difficult topics or showing you exactly how to complete a task.
- The CD contains 90 minutes of new, professional-grade video of me explaining the hands-on concepts discussed throughout the book, such as swapping out a motherboard, properly installing a processor, and installing hard drives. For somebody who has never opened up her system or disassembled a computer, these videos will be a lifesaver. These videos also will be extremely helpful for instructors who teach PC hardware upgrading and repair. I also show you how to identify your motherboard, processor, chipset, memory, connectors, and much more. Some of the latest hardware, including the Pentium 4, is featured. The videos, along with the new illustrations and photographs, will greatly enhance any classroom or seminar using this book.
- Chapter 13, "Optical Storage," is completely rewritten to cover the latest in optical drive technology. Coverage of everything from the first CD-ROM drives to the latest DVD+RW (rewritable) drives has been added in great detail. This includes extensive coverage of the popular CD-RW format that seems to be replacing the floppy drive as the industry standard removable-media format. DVD coverage has been greatly extended, especially the new (and possibly confusing) DVD recordable and rewritable standards. The time for rewritable DVD is now, and with at least four different (and somewhat incompatible) recordable/rewritable DVD standards, you'll want to read this chapter thoroughly before making a purchase.
- Chapter 7, "The IDE Interface," has extensive updates covering the latest breakthroughs in capacity and speed for ATA/IDE drives. There is coverage of the latest ATA-6 standard, as well as the new Serial-ATA, which is poised to dramatically change the connection between drives and motherboards.
- Chapter 21, "Power Supply and Chassis/Case," has been extensively updated to cover the latest developments, including the new ATX12V standard for use with the new high-powered processors like the Pentium 4. Also included are several new figures and information on Power Factor Correction, which is included in many of the new supplies on the market. There is also a section detailing the problems with one very popular PC manufacturer and its use of nonstandard power supply wiring. You'll definitely want to read this before upgrading any of your systems.
- More than 100 pages of new content covering the gamut of changes in the PC hardware industry, including:
    - Deep coverage of Intel and AMD processors, including Intel's Itanium and Pentium 4 processor as well as AMD's Athlon and Duron. I cover these critical changes in the CPU industry including 1GHz processors, new high speed 266MHz and 400MHz processor buses, and the evolution of 64-bit computing.

- RDRAM and SDRAM—A year ago, industry forecasters were betting the farm on RDRAM. Today, RDRAM still remains a somewhat expensive memory option that some say fails to significantly out-perform DDR SDRAM, which is far less expensive and is readily available. Both types are covered in detail.
- As the bevy of hot, new processors from Intel and AMD begin hitting the market, you'll need new, improved motherboards. I delve into these new motherboard architectures, including the 400MHz motherboard bus designed for the Pentium 4 processor, as well as the 266MHz bus used by the AMD Athlon. You'll also learn about new processor sockets, including Socket 423 for the Pentium 4.
- Want to supercharge your PC for hardcore game performance? I give you the inside scoop on today's hottest audio and 3D video cards that bring 3D gaming to a disturbing reality.
- High-speed Internet connectivity isn't just something you can have at the office anymore. I dig into the latest high-speed connectivity options—such as DSL, CATV (cable modems), ISDN, and DirecPC (satellite)—that will make your trusty 56Kbps modem pale in comparison.

Although these are the major changes to the core of the book, every chapter has seen substantial updates. If you thought the additions to the 12th Edition were incredible, you'll appreciate the further enhancements and additions to the new 13th Edition. It is the most comprehensive and complete edition since I wrote the first edition 13 years ago!

The 13th Edition includes more detailed troubleshooting advice that will help you track down problems with your memory, system resources, new drive installations, BIOS, I/O addresses, video and audio performance, modems, and much more.

I also focus on software problems, starting with the basics of how an operating system such as DOS or Windows works with your system hardware to start your system. You also learn how to troubleshoot and avoid problems involving system hardware, the operating system, and applications software.

This book is the result of years of research and development in the production of my PC hardware, operating system, and data recovery seminars. Since 1982, I have personally taught (and still teach) thousands of people about PC troubleshooting, upgrading, maintenance, repair, and data recovery. This book represents the culmination of many years of field experience and knowledge culled from the experiences of thousands of others. What originally started out as a simple course workbook has over the years grown into a complete reference on the subject. Now you can benefit from this experience and research.

Book Objectives

Upgrading and Repairing PCs focuses on several objectives. The primary objective is to help you learn how to maintain, upgrade, and repair your PC system. To that end, *Upgrading and Repairing PCs* helps you fully understand the family of computers that has grown from the original IBM PC, including all PC-compatible systems. This book discusses all areas of system improvement, such as motherboards, processors, memory, and even case and power-supply improvements. The book discusses proper system and component care, specifies the most failure-prone items in various PC systems, and tells you how to locate and identify a failing component. You'll learn about powerful diagnostics hardware and software that enable a system to help you determine the cause of a problem and how to repair it.

PCs are moving forward rapidly in power and capabilities. Processor performance increases with every new chip design. *Upgrading and Repairing PCs* helps you gain an understanding of all the processors used in PC-compatible computer systems.

This book covers the important differences between major system architectures from the original Industry Standard Architecture (ISA) to the latest in PCI and AGP systems. *Upgrading and Repairing PCs* covers each of these system architectures and their adapter boards to help you make decisions about which type of system you want to buy in the future, and to help you upgrade and troubleshoot such systems.

The amount of storage space available to modern PCs is increasing geometrically. *Upgrading and Repairing PCs* covers storage options ranging from larger, faster hard drives to state-of-the-art storage devices. In addition, it provides detailed information on upgrading and troubleshooting system RAM.

When you finish reading this book, you should have the knowledge to upgrade, troubleshoot, and repair almost all systems and components.

Is This Book for You?

Yes.

Upgrading and Repairing PCs is designed for people who want a thorough understanding of how their PC systems work. Each section fully explains common and not-so-common problems, what causes problems, and how to handle problems when they arise. You will gain an understanding of disk configuration and interfacing, for example, that can improve your diagnostics and troubleshooting skills. You'll develop a feel for what goes on in a system so you can rely on your own judgment and observations and not some table of canned troubleshooting steps.

Upgrading and Repairing PCs is written for people who will select, install, configure, maintain, and repair systems they or their companies use. To accomplish these tasks, you need a level of knowledge much higher than that of an average system user. You must know exactly which tool to use for a task and how to use the tool correctly. This book can help you achieve this level of knowledge.

Scott has taught millions of people to upgrade and build PCs. Some of his students are computer experts, and some are computer novices. But they all have one thing in common: They believe Scott's book changed their lives. Scott can teach anyone.

Chapter-by-Chapter Breakdown

This book is organized into chapters that cover the components of a PC system. A few chapters serve to introduce or expand in an area not specifically component related, but most parts in the PC have a dedicated chapter or section, which will aid you in finding the information you want. Also note that the index has been improved greatly over previous editions, which will further aid in finding information in a book of this size.

Chapters 1 and 2 of this book serve primarily as an introduction. Chapter 1, "Personal Computer Background," begins with an introduction to the development of the original IBM PC and PC-compatibles. This chapter incorporates some of the historical events that led to the development of the microprocessor and the PC. Chapter 2, "PC Components, Features, and System Design," provides information about the various types of systems you encounter and what separates one type of system from another, including the types of system buses that differentiate systems. Chapter 2 also provides an overview of the types of PC systems that help build a foundation of knowledge essential for the remainder of the book, and it offers some insight as to how the PC market is driven and where components and technologies are sourced.

Chapter 3, "Microprocessor Types and Specifications," includes detailed coverage of Itanium, Pentium 4, Pentium III, Pentium II, Celeron, Xeon, and earlier central processing unit (CPU) chips as well as Intel-compatible processors from AMD, including the Athlon, Duron, and K6 series; processors from Cyrix; and other vendors as well. The processor is one of the most important parts of a PC, and this book features more extensive and updated processor coverage than ever before. I dig deeply into the latest processor-upgrade socket and slot specifications, including expanded coverage of Socket 423 for the Pentium 4, Socket A for AMD Athlon and Duron processors, and Socket 370 (PGA370) for the FCPGA (Flip Chip Pin Grid Array) Pentium III and Celeron processors. Chapter 3 also includes new coverage of spotting overclocked processors. These are processors that have been modified by unscrupulous resellers to run faster than their rated speeds. These chips are then sold to the consumer as faster processors. I show you how to spot and avoid fakes.

Chapter 4, "Motherboards and Buses," covers the motherboard, chipsets, motherboard components, and system buses in detail. This chapter contains discussions of new motherboard designs, including the ATX, Micro-ATX, Flex-ATX, and NLX form factors. This new edition features the most accurate, detailed, and complete reference to PC motherboards that you will find anywhere. I also cover the latest chipsets for current processor families, including all new coverage of the Intel 800 series chipsets—such as the 810, 815, 820, 840, and 850—as well as complete coverage of the older 440 chipset family and the new chipsets from AMD, VIA, SiS, and ALI. This chapter also covers special bus architectures and devices, including high-speed Peripheral Component Interconnect (PCI), Accelerated Graphics Port (AGP), and the 266MHz and faster processor buses. A detailed reference comparing virtually all PC buses is included.

Chapter 5, "BIOS," has a detailed discussion of the system BIOS, including types, features, and upgrades. This has grown from a section of the book to a complete chapter, with more information on this subject than ever before. Also included is updated coverage of the BIOS, with detailed coverage of BIOS setup utilities, Flash upgradable BIOSes, and Plug and Play BIOS.

See the exhaustive list of BIOS codes and error messages included on the CD-ROM. They're all printable, so be sure to print the codes for your BIOS in case you need them later.

Chapter 6, "Memory," gives a detailed discussion of PC memory, including the latest in cache and main memory specifications. Next to the processor and motherboard, the system memory is one of the most important parts of a PC. Memory is also one of the most difficult things to understand because it is somewhat intangible and it's not always obvious how it works. This chapter has received extensive updates to make memory technology more understandable, as well as to cover the newest technologies on the market today. Coverage of cache memory has been updated to help you understand this difficult subject and know exactly how the various levels of cache in a modern PC function, interact, and affect system performance. In particular, new types of memory, including Double Data Rate SDRAM (DDR) and Rambus DRAM (RDRAM), are examined. Also discussed is increasing system memory capacity with SIMM, DIMM, DDR DIMM, and RIMM modules and increasing system reliability with ECC RAM.

Chapter 7, "The IDE Interface," provides a detailed discussion of ATA/IDE, including types and specifications. This covers the Ultra-ATA modes that allow 100MB/sec operation, as well as the new Serial ATA that is destined to replace the parallel ATA we have been using for the last 14 years.

Chapter 8, "The SCSI Interface," discusses SCSI, including the new higher-speed modes possible with SCSI-3. This chapter covers the new Low Voltage Differential signaling used by some of the higher-speed devices on the market, as well as the latest information on cables, terminators, and SCSI configurations. This chapter also includes the latest on UltraSCSI.

Chapter 9, "Magnetic Storage Principles," details the inner workings of magnetic storage devices such as disk and tape drives. Regardless of whether you understood electromagnetism in high school science, this chapter breaks down these difficult concepts and presents them in a way that will change the way you think about data and drives.

Chapter 10, "Hard Disk Storage," breaks down how data is stored to your drives and how it is retrieved when you double-click a file.

Chapter 11, "Floppy Disk Storage," takes an inside view of the venerable floppy disk drive. You learn how to properly connect these drives as well as how information is written to a floppy.

Chapter 12, "High-Capacity Removable Storage," covers removable storage drives, such as SuperDisk (LS-120), Iomega Zip, Jaz, and Click! drives, as well as provides all-new coverage of magnetic tape drives.

Chapter 13, "Optical Storage," covers optical drives and storage using CD and DVD technology, including CD recorders, rewritable CDs, and other optical technologies. This chapter includes detailed steps and advice for avoiding buffer underruns, creating bootable CDs, burning music CDs, and selecting the most reliable media. Extensive coverage of DVD has been added, including the new recordable and rewritable formats.

Chapter 14, "Physical Drive Installation and Configuration," covers how to install drives of all types in a PC system. You learn how to format and partition hard drives after they are installed.

Chapter 15, "Video Hardware," covers everything there is to know about video cards and displays. If you're a gamer or multimedia buff, you'll want to read about choosing the right 3D graphics accelerator. The leading technologies are compared, and I help you choose the right card. I also dig into flat-panel monitors and help you decide whether they're worth the investment.

Chapter 16, "Audio Hardware," covers sound and sound-related devices, including sound boards and speaker systems. I help you optimize your system's audio performance for gaming, listening to CDs, and recording and playing MP3 music files.

Chapter 17, "I/O Interfaces from Serial and Parallel to IEEE-1394 and USB," covers the standard serial and parallel ports still found in most systems, as well as newer technology such as USB and iLink (FireWire). I also cover USB 2.0, which is 40 times faster than the original USB specification!

Chapter 18, "Input Devices," covers keyboards, pointing devices, and game ports used to communicate with a PC. I also discuss wireless mice and keyboards.

Chapter 19, "Internet Connectivity," compares high-speed connectivity methods that have come to the home desktop, including DSL, CATV, and DirecPC.

Chapter 20, "Local Area Networking," has been heavily updated for this edition to cover setting up an Ethernet network in your home or small office. I show you how to install NICs, make your own Ethernet cables, and set up Windows networking services.

Chapter 21, "Power Supply and Chassis/Case," is a detailed investigation of the power supply, which still remains the primary cause for PC system problems and failures. Coverage of the new ATX12V standard has been added, as well as additional information on keeping your system cool.

Chapter 22, "Portable PCs," covers portable systems, including laptop and notebook systems. It also focuses on all the technology unique and peculiar to portable systems, such as mobile processors, display, battery, and other technologies.

Chapter 23, "Building or Upgrading Systems," is where I show you how to select the parts you'll need for your upgrade or to build a PC from scratch. Then, I walk you step by step through the process. This chapter is loaded with professional photos that help you follow along.

Chapter 24, "PC Diagnostics, Testing, and Maintenance," covers diagnostic and testing tools and procedures. This chapter also adds more information on general PC troubleshooting and problem determination. Here, I show you what the prepared PC technician has in his toolkit. I also show you a few tools you might have never seen or used before.

Chapter 25, "File Systems and Data Recovery," covers file systems and data recovery procedures. If you've ever wondered why you should upgrade from FAT16 to FAT32, you should read this chapter.

The 13th Edition CD-ROM

In addition to the sweeping changes in the printed book, I've also included a CD packed with useful video how-to and technical documentation that will make your job easier—whether you're upgrading your PC at home or managing a stable of PCs at the office:

- **Scott Mueller on video!**—The video we made for the 12th Edition was so well received, he went back into the studio and taped 90 minutes of all-new video, showing you step-by-step upgrading and repairing procedures, such as memory and processor upgrades, motherboard swapping, and using the tools of the trade. I show you all the essentials skills you need to learn to build and maintain your own PCs. I cover the Pentium 4 extensively, showing the unique requirements for chassis and heatsinks the high-powered processors require. I also go through the steps in bringing a new system to life and troubleshooting one that seems dead.
- **Hundreds of pages of legacy and technical documentation!**—Rather than eliminate outdated coverage, I've placed this valuable content (especially for PC repair technicians or support staff) in a printable PDF format. The Technical Reference section of the CD contains hundreds of pages of content from previous editions of the book.
- **Searchable vendor database!**—This custom database contains hundreds of entries of contact information for the industry's leading manufacturers and vendors. It's like having my Rolodex on your computer. This database is fully searchable and printable.
- **Searchable hard drive specifications!**—This custom database contains literally thousands of specs for nearly any hard drive in production and most any other drive you'll ever encounter. Need to know the number of cylinders or tracks for an antiquated Seagate drive? Chances are you'll find it here.
- **Entire previous editions!**—Need to find a table from a previous edition? Looking for detailed coverage of legacy standards and system design? Look no further because I've also included four entire editions of the book on this CD—in printable format. See the CD for printable PDF versions of the 6th, 8th, 10th, 11th, and 12th editions.
- **Printers and scanners coverage in printable PDF!**—This full-length chapter covers laser, ink jet, dye sublimation, thermal wax transfer, and dot matrix printers in detail, as well as scanners and PostScript technology.

Scott's Web Site—*upgradingandrepairingpcs.com*

Don't miss my book Web site at `www.upgradingandrepairingpcs.com`! Here, you'll find a cache of helpful material to go along with the book you're holding. I've loaded this site with tons of material, from video clips to monthly book updates. I use this spot to keep you updated throughout the year on major changes in the PC hardware industry. Each month, I write new articles covering new technologies released after this book was printed. These articles are archived so you can refer to them anytime.

I also use this site to post your reader questions and my answers. This Frequently Asked Questions (FAQ) is a tremendous resource because you benefit from the hundreds of reader emails I answer each month. Log on and post a question. I endeavor to answer each and every email personally.

You'll also find exclusive video clips available nowhere else!

I also use this site to tell you about some of the other fantastic *Upgrading and Repairing PCs* products I work on, including

- *Upgrading and Repairing PCs, A+ Certification Study Guide, Second Edition*
- *Upgrading and Repairing PCs, Technician's Portable Reference, Third Edition*
- *Upgrading and Repairing PCs, Academic Edition*
- *Upgrading and Repairing Networks, Third Edition*

Don't miss out on this valuable resource!

A Personal Note

When asked which was his favorite Corvette, Dave McLellan, former manager of the Corvette platform at General Motors, always said "Next year's model." Now with the new 13th Edition, next year's model has just become this year's model, until next year that is....

I believe this book is absolutely the best book of its kind on the market, and that is due in a large part to the extensive feedback I have received from both my seminar attendees and book readers. I am so grateful to everyone who has helped me with this book over the last 13 years as well as all the loyal readers who have been reading this book, many of you since the first edition came out. I have had personal contact with many thousands of you in the seminars I have been teaching since 1982, and I enjoy your comments and even your criticisms tremendously. Using this book in a teaching environment has been a major factor in its development. Some of you might be interested to know that I originally began writing this book in early 1985; back then it was self-published and used exclusively in my PC hardware seminars before being professionally published by Que in 1988. In one way or another, I have been writing and rewriting this book for more than 17 years! In the more than 13 years since it was professionally published, *Upgrading and Repairing PCs* has proven to be not only the first but also the most comprehensive and yet approachable and easy-to-understand book of its kind. With the new 13th Edition, it is even better than ever. Your comments, suggestions, and support have helped this book to become the best PC hardware book on the market. I look forward to hearing your comments after you see this exciting new edition.

Scott

CHAPTER 1

Personal Computer Background

Computer History—Before Personal Computers

Many discoveries and inventions have directly and indirectly contributed to the development of the personal computer as we know it today. Examining a few important developmental landmarks can help bring the entire picture into focus.

The first computers of any kind were simple calculators. Even these evolved from mechanical devices to electronic digital devices.

Timeline

The following is a timeline of some significant events in computer history. It is not meant to be complete, just a representation of some of the major landmarks in computer development:

1617 John Napier creates “Napier’s Bones,” wooden or ivory rods used for calculating.

1642 Blaise Pascal introduces the Pascaline digital adding machine.

1822 Charles Babbage conceives the Difference Engine and later the Analytical Engine, a true general-purpose computing machine.

1906 Lee De Forest patents the vacuum tube triode, used as an electronic switch in the first electronic computers.

1937 John V. Atanasoff begins work on the Atanasoff-Berry Computer (ABC), which would later be officially credited as the first electronic computer.

1943 Alan Turing develops the Colossus, a secret British code-breaking computer designed to decode German secret messages.

1945 John von Neumann writes “First Draft of a Report on the EDVAC,” in which he outlines the architecture of the modern stored-program computer.

1946 ENIAC is introduced, an electronic computing machine built by John Mauchly and J. Presper Eckert.

1947 On December 23, William Shockley, Walter Brattain, and John Bardeen successfully test the point-contact transistor, setting off the semiconductor revolution.

1949 Maurice Wilkes assembles the EDSAC, the first practical stored-program computer, at Cambridge University.

1950 Engineering Research Associates of Minneapolis builds the ERA 1101, one of the first commercially produced computers.

1952 The UNIVAC I delivered to the U.S. Census Bureau is the first commercial computer to attract widespread public attention.

1953 IBM ships its first electronic computer, the 701.

1954 A silicon-based junction transistor, perfected by Gordon Teal of Texas Instruments, Inc., brings a tremendous reduction in costs.

1954 The IBM 650 magnetic drum calculator establishes itself as the first mass-produced computer, with the company selling 450 in one year.

1955 Bell Laboratories announces the first fully transistorized computer, TRADIC.

1956 MIT researchers build the TX-0, the first general-purpose, programmable computer built with transistors.

1956 The era of magnetic disk storage dawns with IBM’s shipment of a 305 RAMAC to Zellerbach Paper in San Francisco.

1958 Jack Kilby creates the first integrated circuit at Texas Instruments to prove that resistors and capacitors could exist on the same piece of semiconductor material.

1959 IBM's 7000 series mainframes are the company's first transistorized computers.

1959 Robert Noyce's practical integrated circuit, invented at Fairchild Camera and Instrument Corp., allows printing of conducting channels directly on the silicon surface.

1960 Bell Labs designs its Dataphone, the first commercial modem, specifically for converting digital computer data to analog signals for transmission across its long-distance network.

1960 The precursor to the minicomputer, DEC's PDP-1, sells for $120,000.

1961 According to *Datamation* magazine, IBM has an 81.2-percent share of the computer market in 1961, the year in which it introduces the 1400 Series.

1964 CDC's 6600 supercomputer, designed by Seymour Cray, performs up to three million instructions per second—a processing speed three times faster than that of its closest competitor, the IBM Stretch.

1964 IBM announces System/360, a family of six mutually compatible computers and 40 peripherals that could work together.

1964 Online transaction processing makes its debut in IBM's SABRE reservation system, set up for American Airlines.

1965 Digital Equipment Corp. introduces the PDP-8, the first commercially successful minicomputer.

1966 Hewlett-Packard enters the general-purpose computer business with its HP-2115 for computation, offering a computational power formerly found only in much larger computers.

1970 Computer-to-computer communication expands when the Department of Defense establishes four nodes on the ARPAnet: two at University of California campuses (one at Santa Barbara and one at Los Angeles) and one each at SRI International and the University of Utah.

1971 A team at IBM's San Jose Laboratories invents the 8-inch floppy disk.

1971 The first advertisement for a microprocessor, the Intel 4004, appears in *Electronic News*.

1971 The Kenbak-1, one of the first personal computers, advertises for $750 in *Scientific American*.

1972 Hewlett-Packard announces the HP-35 as "a fast, extremely accurate electronic slide rule" with a solid-state memory similar to that of a computer.

1972 Intel's 8008 microprocessor makes its debut.

1972 Steve Wozniak builds his "blue box," a tone generator to make free phone calls.

1973 Robert Metcalfe devises the Ethernet method of network connection at the Xerox Palo Alto Research Center.

1973 The Micral is the earliest commercial, non-kit personal computer based on a microprocessor, the Intel 8008.

1973 The TV Typewriter, designed by Don Lancaster, provides the first display of alphanumeric information on an ordinary television set.

1974 Researchers at the Xerox Palo Alto Research Center design the Alto, the first work station with a built-in mouse for input.

1974 Scelbi advertises its 8H computer, the first commercially advertised U.S. computer based on a microprocessor, Intel's 8008.

1975 Telenet, the first commercial packet-switching network and civilian equivalent of ARPAnet, is born.

1975 The January edition of *Popular Electronics* features the Altair 8800, which is based on Intel's 8080 microprocessor, on its cover.

1975 The visual display module (VDM) prototype, designed by Lee Felsenstein, marks the first implementation of a memory-mapped alphanumeric video display for personal computers.

1976 Steve Wozniak designs the Apple I, a single-board computer.

1976 The 5 1/4-inch flexible disk drive and disk are introduced by Shugart Associates.

1976 The Cray I makes its name as the first commercially successful vector processor.

1977 Tandy Radio Shack introduces the TRS-80.

1977 Apple Computer introduces the Apple II.

1977 Commodore introduces the PET (Personal Electronic Transactor).

1978 The VAX 11/780 from Digital Equipment Corp. features the capability to address up to 4.3GB of virtual memory, providing hundreds of times the capacity of most minicomputers.

1979 Motorola introduces the 68000 microprocessor.

1980 John Shoch, at the Xerox Palo Alto Research Center, invents the computer "worm," a short program that searches a network for idle processors.

1980 Seagate Technology creates the first hard disk drive for microcomputers, the ST-506.

1980 The first optical data storage disk has 60 times the capacity of a 5 1/4-inch floppy disk.

1981 Xerox introduces the Star, the first personal computer with a graphical user interface (GUI).

1981 Adam Osborne completes the first portable computer, the Osborne I, which weighs 24 pounds and costs $1,795.

1981 IBM introduces its PC, igniting a fast growth of the personal computer market. The IBM PC is the grandfather of all modern PCs.

1981 Sony introduces and ships the first 3 1/2-inch floppy drives and disks.

1983 Apple introduces its Lisa, which incorporates a GUI very similar to that first introduced on the Xerox Star.

1983 Compaq Computer Corp. introduces its first PC clone that uses the same software as the IBM PC.

1984 Apple Computer launches the Macintosh, the first successful mouse-driven computer with a GUI, with a single $1.5 million commercial during the 1984 Super Bowl.

1984 IBM releases the PC-AT (PC Advanced Technology), three times faster than original PCs and based on the Intel 286 chip. The AT introduces the 16-bit ISA bus and is the computer all modern PCs are based on.

1985 Philips introduces the CD-ROM.

1986 Compaq announces the Deskpro 386, the first computer on the market to use what was then Intel's new 386 chip.

1987 IBM introduces its PS/2 machines, which make the 3 1/2-inch floppy disk drive and VGA video standard for PCs. The PS/2 also introduces the MicroChannel Architecture (MCA) bus, the first plug-and-play bus for PCs.

1988 Apple cofounder Steve Jobs, who left Apple to form his own company, unveils the NeXT.

1988 Compaq and other PC-clone makers develop Enhanced Industry Standard Architecture (EISA), which unlike MicroChannel retains backward-compatibility with the existing ISA bus.

1988 Robert Morris's worm floods the ARPAnet. The 23-year-old Morris, the son of a computer security expert for the National Security Agency, sends a nondestructive worm through the Internet, causing problems for about 6,000 of the 60,000 hosts linked to the network.

1989 Intel releases the 486 (P4) microprocessor, which contains more than one million transistors. Intel also introduces 486 motherboard chipsets.

1990 The World Wide Web (WWW) is born when Tim Berners-Lee, a researcher at CERN—the high-energy physics laboratory in Geneva—develops Hypertext Markup Language (HTML).

1993 Intel releases the Pentium (P5) processor. Intel shifts from numbers to names for its chips after it learns it's impossible to trademark a number. Intel also releases motherboard chipsets and for the first time complete motherboards as well.

1995 Intel releases the Pentium Pro processor, the first in the P6 processor family.

1995 Microsoft releases Windows 95, the first mainstream 32-bit operating system, in a huge rollout.

1997 Intel releases the Pentium II processor, essentially a Pentium Pro with MMX features added.

1997 AMD introduces the K6, which is compatible with the Intel P5 (Pentium).

1998 Microsoft releases Windows 98.

1998 Intel releases the Celeron, a low-cost version of the Pentium II processor with reduced L2 cache.

1999 Intel releases the Pentium III, essentially a Pentium II with SSE (Streaming SIMD Extensions) added.

1999 AMD introduces the Athlon.

2000 Microsoft releases Windows Me (Millennium Edition) and Windows 2000.

2000 Both Intel and AMD introduce processors running at 1GHz.

2000 AMD introduces the Duron, a low-cost Athlon with reduced L2 cache.

2000 Intel introduces the Pentium IV, the latest processor in the Intel Architecture 32-bit (IA-32) family.

2000 Intel releases the Itanium processor, their first 64-bit (IA-64) processor for PCs.

Mechanical Calculators

One of the earliest calculating devices on record is the abacus, which has been known and widely used for more than 2,000 years. The abacus is a simple wooden rack holding parallel rods on which beads are strung. When these beads are manipulated back and forth according to certain rules, several types of arithmetic operations can be performed.

Math with standard Arabic numbers found its way to Europe in the eighth and ninth centuries. In the early 1600s, a man named Charles Napier (the inventor of logarithms) developed a series of rods (later called Napier's Bones) that could be used to assist with numeric multiplication.

Blaise Pascal is normally credited with building the first digital calculating machine in 1642. It could perform the addition of numbers entered on dials and was intended to help his father, who was a tax collector. Then in 1671, Gottfried Wilhelm von Leibniz invented a calculator that was finally built in 1694. His calculating machine could not only add, but by successive adding and shifting, could also multiply.

In 1820, Charles Xavier Thomas developed the first commercially successful mechanical calculator that could not only add but also subtract, multiply, and divide. After that, a succession of ever improving mechanical calculators created by various other inventors followed.

The First Mechanical Computer

Charles Babbage, a mathematics professor in Cambridge, England, is considered by many to be the father of computers because of his two great inventions—each a different type of mechanical computing engine.

The Difference Engine, as he called it, was conceived in 1812 and solved polynomial equations by the method of differences. By 1822, he had built a small working model of his Difference Engine for demonstration purposes. With financial help from the British government, Babbage started construction of a full-scale model in 1823. It was intended to be steam-powered and fully automatic and would even print the resulting tables.

Babbage continued work on it for 10 years, but by 1833 he had lost interest because he now had an idea for an even better machine, something he described as a general-purpose, fully program-controlled, automatic mechanical digital computer. Babbage called his new machine an Analytical Engine. The plans for the Analytical Engine specified a parallel decimal computer operating on numbers (words) of 50 decimal digits and with a storage capacity (memory) of 1,000 such numbers. Built-in operations were to include everything that a modern general-purpose computer would need, even the all-important conditional function, which would allow instructions to be executed in an order depending on certain conditions, not just in numerical sequence. In modern computers, this conditional capability is manifested in the `IF` statement found in modern computer languages. The Analytical Engine was also intended to use punched cards, which would control or program the machine. The machine was to operate automatically by steam power and would require only one attendant.

The Analytical Engine is regarded as the first real predecessor to a modern computer because it had all the elements of what is considered a computer today. These included

- *An input device.* Using an idea similar to the looms used in textile mills at the time, a form of punched cards supplied the input.
- *A control unit.* A barrel-shaped section with many slats and studs was used to control or program the processor.
- *A processor (or calculator).* A computing engine containing hundreds of axles and thousands of gears about 10 feet tall.
- *Storage.* A unit containing more axles and gears that could hold 1,000 50-digit numbers.
- *An output device.* Plates designed to fit in a printing press, used to print the final results.

Alas, this potential first computer was never actually completed because of the problems in machining all the precision gears and mechanisms required. The tooling of the day was simply not good enough.

An interesting side note is that the punched card idea first proposed by Babbage finally came to fruition in 1890. That year a competition was held for a better method to tabulate the U.S. Census information, and Herman Hollerith—a Census Department employee—came up with the idea for punched cards. Without these cards, department employees had estimated the census data would take years to tabulate; with these cards they were able to finish in about six weeks. Hollerith went on to found the Tabulating Machine Company, which later became known as IBM.

IBM and other companies at the time developed a series of improved punch-card systems. These systems were constructed of electromechanical devices, such as relays and motors. Such systems included features to automatically feed in a specified number of cards from a "read-in" station; perform operations, such as addition, multiplication, and sorting; and feed out cards punched with results. These punched-card computing machines could process 50–250 cards per minute, with each card holding up to 80-digit numbers. The punched cards not only provided a means of input and output, but they also served as a form of memory storage. Punched-card machines did the bulk of the world's computing for more than 50 years and gave many of the early computer companies their starts.

Electronic Computers

A physicist named John V. Atanasoff (with associate Clifford Berry) is credited with creating the first true digital electronic computer during 1937–1942, while working at Iowa State University. The Atanasoff-Berry Computer (called the ABC) was the first to use modern digital switching techniques and vacuum tubes as switches, and it introduced the concepts of binary arithmetic and logic circuits. This was made legally official on October 19, 1973, when following a lengthy court trial, U.S. Federal Judge Earl R. Larson voided the ENIAC patent of Eckert and Mauchly and named Atanasoff as the inventor of the first electronic digital computer.

Military needs during World War II caused a great thrust forward in the evolution of computers. In 1943, Alan Turing completed a secret British code-breaking computer called Colossus, which was used to decode German secret messages. Unfortunately, Turing's work went largely uncredited because Colossus was kept secret until many years after the war.

Besides code-breaking, systems were needed to calculate weapons trajectory and other military functions. In 1946, John P. Eckert, John W. Mauchly, and their associates at the Moore School of Electrical Engineering at the University of Pennsylvania built the first large-scale electronic computer for the military. This machine became known as *ENIAC*, the *Electrical Numerical Integrator and Calculator*. It operated on 10-digit numbers and could multiply two such numbers at the rate of 300 products per second by finding the value of each product from a multiplication table stored in its memory. ENIAC was about 1,000 times faster than the previous generation of electromechanical relay computers.

ENIAC used about 18,000 vacuum tubes, occupied 1,800 square feet (167 square meters) of floor space, and consumed about 180,000 watts of electrical power. Punched cards served as the input and output; registers served as adders and also as quick-access read/write storage.

The executable instructions composing a given program were created via specified wiring and switches that controlled the flow of computations through the machine. As such, ENIAC had to be rewired and switched for each program to be run.

Although Eckert and Mauchly were originally given a patent for the electronic computer, it was later voided and the patent awarded to John Atanasoff for creating the Atanasoff-Berry Computer.

Earlier in 1945, the mathematician John von Neumann demonstrated that a computer could have a very simple, fixed physical structure and yet be capable of executing any kind of computation effectively by means of proper programmed control without the need for any changes in hardware. In other words, you could change the program without rewiring the system. The *stored-program technique*, as von Neumann's ideas are known, became fundamental for future generations of high-speed digital computers and has become universally adopted.

The first generation of modern programmed electronic computers to take advantage of these improvements appeared in 1947. This group of machines included EDVAC and UNIVAC, the first commercially available computers. These computers included, for the first time, the use of true random access memory (RAM) for storing parts of the program and data that is needed quickly. Typically, they were programmed directly in machine language, although by the mid-1950s progress had been made in several aspects of advanced programming. The standout of the era is the UNIVAC (Universal Automatic Computer), which was the first true general-purpose computer designed for both alphabetical and numerical uses. This made the UNIVAC a standard for business, not just science and the military.

Modern Computers

From UNIVAC to the present, computer evolution has moved very rapidly. The first-generation computers were known for using vacuum tubes in their construction. The generation to follow would use the much smaller and more efficient transistor.

From Tubes to Transistors

Any modern digital computer is largely a collection of electronic switches. These switches are used to represent and control the routing of data elements called *binary digits* (or *bits*). Because of the on or off nature of the binary information and signal routing used by the computer, an efficient electronic switch was required. The first electronic computers used vacuum tubes as switches, and although the tubes worked, they had many problems.

The type of tube used in early computers was called a *triode* and was invented by Lee De Forest in 1906. It consists of a cathode and a plate, separated by a control grid, suspended in a glass vacuum tube. The cathode is heated by a red-hot electric filament, which causes it to emit electrons that are attracted to the plate. The control grid in the middle can control this flow of electrons. By making it negative, the electrons are repelled back to the cathode; by making it positive, they are attracted toward the plate. Thus, by controlling the grid current, you can control the on/off output of the plate.

Unfortunately, the tube was inefficient as a switch. It consumed a great deal of electrical power and gave off enormous heat—a significant problem in the earlier systems. Primarily because of the heat they generated, tubes were notoriously unreliable—in larger systems, one failed every couple of hours or so.

The invention of the transistor, or semiconductor, was one of the most important developments leading to the personal computer revolution. The transistor was first invented in 1947, and announced in 1948, by Bell Laboratory engineers John Bardeen and Walter Brattain. Bell associate William Shockley invented the junction transistor a few months later, and all three jointly shared the Nobel Prize in Physics in 1956 for inventing the transistor. The transistor, which essentially functions as a solid-state electronic switch, replaced the less-suitable vacuum tube. Because the transistor was so much smaller and consumed significantly less power, a computer system built with transistors was also much smaller, faster, and more efficient than a computer system built with vacuum tubes.

Transistors are made primarily from the elements silicon and germanium, with certain impurities added. Depending on the impurities added—its electron content—the material becomes known as either N-Type (negative) or P-Type (positive). Both types are conductors, allowing electricity to flow in either direction. However, when the two types are joined, a barrier is formed where they meet that allows current to flow only in one direction when a voltage is present in the right polarity. This is why they are normally called semiconductors.

A transistor is made by placing two P-N junctions back to back. They are made by sandwiching a thin wafer of one type of semiconductor material between two wafers of the other type. If the wafer in between is made from P-type material, the transistor is designated a NPN. If the wafer in between is N-type, the transistor is designated PNP.

In an NPN transistor, the N-type semiconductor material on one side of the wafer is called the *emitter* and is normally connected to a negative current. The P-type material in the center is called the *base*. And the N-type material on the other side of the base is called the *collector*.

An NPN transistor compares to a triode tube such that the emitter is equivalent to the cathode, the base is equivalent to the grid, and the collector is equivalent to the plate. By controlling the current at the base, you can control the flow of current between the emitter and collector.

Compared to the tube, the transistor is much more efficient as a switch and can be miniaturized to microscopic scale. The latest Pentium II and III microprocessors consist of more than 27 million transistors on a single chip die!

The conversion from tubes to transistors began the trend toward miniaturization that continues to this day. Today's small laptop (or palmtop) PC systems, which run on batteries, have more computing power than many earlier systems that filled rooms and consumed huge amounts of electrical power.

Integrated Circuits

The third generation of modern computers is known for using integrated circuits instead of individual transistors. In 1959, engineers at Texas Instruments invented the *integrated circuit (IC)*, a semiconductor circuit that contains more than one transistor on the same base (or substrate material) and connects the transistors without wires. The first IC contained only six transistors. By comparison, the Intel Pentium Pro microprocessor used in many of today's high-end systems has more than 5.5 million transistors, and the integral cache built into some of these chips contains as many as an additional 32 million transistors! Today, many ICs have transistor counts in the multimillion range.

The First Microprocessor

In 1998, Intel celebrated its 30th anniversary. Intel was founded on July 18, 1968, by Robert Noyce, Gordon Moore, and Andrew Grove. They had a specific goal: to make semiconductor memory practical and affordable. This was not a given at the time, considering that silicon chip–based memory was at least 100 times more expensive than the magnetic core memory commonly used in those days. At the time, semiconductor memory was going for about a dollar a bit, whereas core memory was about a penny a bit. Noyce said, "All we had to do was reduce the cost by a factor of a hundred, then we'd have the market; and that's basically what we did."

By 1970, Intel was known as a successful memory chip company, having introduced a 1Kb memory chip much larger than anything else available at the time. (1Kb equals 1,024 bits, and a byte equals 8 bits. This chip, therefore, stored only 128 bytes—not much by today's standards.) Known as the 1103 dynamic random access memory (DRAM), it became the world's largest-selling semiconductor device by the end of the following year. By this time, Intel had also grown from the core founders and a handful of others to more than 100 employees.

Because of Intel's success in memory chip manufacturing and design, Japanese manufacturer Busicom asked Intel to design a set of chips for a family of high-performance programmable calculators. At the time, all logic chips were custom designed for each application or product. Because most chips had to be custom designed specific to a particular application, no one chip could have any widespread usage.

Busicom's original design for its calculator called for at least 12 custom chips. Intel engineer Ted Hoff rejected the unwieldy proposal and instead designed a single-chip, general-purpose logic device that retrieved its application instructions from semiconductor memory. As the core of a four-chip set, this central processing unit could be controlled by a program that could essentially tailor the function of the chip to the task at hand. The chip was generic in nature, meaning it could function in designs other than calculators. Previous designs were hard-wired for one purpose, with built-in instructions; this chip would read a variable set of instructions from memory, which would control the function of the chip. The idea was to design almost an entire computing device on a single chip that could perform various functions, depending on which instructions it was given.

There was one problem with the new chip: Busicom owned the rights to it. Hoff and others knew that the product had almost limitless application, bringing intelligence to a host of “dumb” machines. They urged Intel to repurchase the rights to the product. While Intel founders Gordon Moore and Robert Noyce championed the new chip, others within the company were concerned that the product would distract Intel from its main focus—making memory. They were finally convinced by the fact that every four-chip microcomputer set included two memory chips. As the director of marketing at the time recalled, “Originally, I think we saw it as a way to sell more memories, and we were willing to make the investment on that basis.”

Intel offered to return Busicom’s $60,000 investment in exchange for the rights to the product. Struggling with financial troubles, the Japanese company agreed. Nobody else in the industry at the time, even at Intel, realized the significance of this deal. Of course, it paved the way for Intel’s future in processors. The result was the 1971 introduction of the 4-bit Intel 4004 microcomputer set (the term *microprocessor* was not coined until later). Smaller than a thumbnail and packing 2,300 transistors, the $200 chip delivered as much computing power as the first electronic computer, ENIAC. By comparison, ENIAC relied on 18,000 vacuum tubes packed into 3,000 cubic feet (85 cubic meters) when it was built in 1946. The 4004 executed 60,000 operations in one second, primitive by today’s standards, but a major breakthrough at the time.

Intel introduced the 8008 microcomputer in 1972, which processed 8 bits of information at a time, twice as much as the original chip. By 1981, Intel’s microprocessor family had grown to include the 16-bit 8086 and the 8-bit 8088 processors. These two chips garnered an unprecedented 2,500 design wins in a single year. Among those designs was a product from IBM that was to become the first PC.

In 1982, Intel introduced the 286 chip. With 134,000 transistors, it provided about three times the performance of other 16-bit processors of the time. Featuring on-chip memory management, the 286 was the first microprocessor that offered software compatibility with its predecessors. This revolutionary chip was first used in IBM’s benchmark PC-AT.

In 1985 came the Intel386 processor. With a new 32-bit architecture and 275,000 transistors, the chip could perform more than 5 million instructions every second (MIPS). Compaq’s DESKPRO 386 was the first PC based on the new microprocessor.

Next out of the block was the Intel486 processor in 1989. The 486 had 1.2 million transistors and the first built-in math coprocessor. It was some 50 times faster than the original 4004, equaling the performance of powerful mainframe computers.

Then, in 1993, Intel introduced the first Pentium processor, setting new performance standards with up to five times the performance of the Intel486 processor. The Pentium processor uses 3.1 million transistors to perform up to 90 MIPS—now up to about 1,500 times the speed of the original 4004.

The first processor in the P6 family, called the Pentium Pro processor, was introduced in 1995. With 5.5 million transistors, it was the first to be packaged with a second die containing high-speed memory cache to accelerate performance. Capable of performing up to 300 MIPS, the Pentium Pro continues to be a popular choice for multiprocessor servers and high-performance workstations.

Intel revised the original P6 (Pentium Pro) and introduced the Pentium II processor in May 1997. Pentium II processors had 7.5 million transistors packed into a cartridge rather than a conventional chip, allowing them to attach the L2 cache chips directly on the module. The Pentium II family was augmented in April 1998, with both the low-cost Celeron processor for basic PCs and the high-end

Pentium II Xeon processor for servers and workstations. Intel followed with the Pentium III in 1999, essentially a Pentium II with SSE (Streaming SIMD Extensions) added.

Around the time the Pentium was establishing its dominance, AMD acquired NexGen, who had been working on their Nx686 processor, and incorporated that design along with a Pentium interface into what would be called the AMD K6. The K6 was both hardware and software compatible with the Pentium, meaning it plugged into the same Socket 7 and could run the same programs. As Intel dropped their Pentium in favor of the Pentium II and III, AMD continued making faster versions of the K6 and made huge inroads in the low-end PC market.

AMD introduced the Athlon in 1999 to compete with Intel head to head in the high-end PC market. Athlon is very successful, and it seems for the first time Intel has real competition.

The year 2000 saw both companies introduce more new chips to the market. AMD premiered both their Athlon Thunderbird and Duron processors. The Duron is essentially an Athlon with a smaller L2 cache designed for lower-cost systems, whereas the Thunderbird uses a more integrated cache to ratchet up the Athlon's performance.

Intel introduced the Pentium IV in 2000, the latest processor in the Intel Architecture 32-bit (IA-32) family. They also announced the Itanium processor (code named Merced), which is the first IA-64 (Intel Architecture-64 bit) processor. Itanium is Intel's first processor with 64-bit instructions and will spawn a whole new category of operating systems and applications while still remaining backward-compatible with 32-bit software.

2000 also saw another significant milestone written into the history books when both Intel and AMD crossed the 1GHz barrier, a speed that many thought could never be accomplished.

Personal Computer History

The fourth and current generation of the modern computer includes those that incorporate microprocessors in their designs. Of course, part of this fourth generation of computers is the personal computer, which itself was made possible by the advent of low-cost microprocessors and memory.

Birth of the Personal Computer

In 1973, some of the first microcomputer kits based on the 8008 chip were developed. These kits were little more than demonstration tools and didn't do much except blink lights. In late 1973, Intel introduced the 8080 microprocessor, which was 10 times faster than the earlier 8008 chip and addressed 64KB of memory. This was the breakthrough the personal computer industry had been waiting for.

A company called MITS introduced the Altair kit in a cover story in the January 1975 issue of *Popular Electronics*. The Altair kit, considered the first personal computer, included an 8080 processor, a power supply, a front panel with a large number of lights, and 256 bytes (not kilobytes) of memory. The kit sold for $395 and had to be assembled. Assembly back then meant you got out your soldering iron to actually finish the circuit boards, not like today where you can assemble a system of premade components with nothing more than a screwdriver.

The Altair included an open architecture system bus called the S-100 bus because it had 100 pins per slot. The open architecture meant that anybody could develop boards to fit in these slots and interface to the system. This prompted various add-ons and peripherals from numerous aftermarket companies. The new processor inspired software companies to write programs, including the CP/M (control program for microprocessors) operating system and the first version of the Microsoft BASIC (beginners all-purpose symbolic instruction code) programming language.

IBM introduced what can be called its first personal computer in 1975. The Model 5100 had 16KB of memory, a built-in 16-line–by–64-character display, a built-in BASIC language interpreter, and a built-in DC-300 cartridge tape drive for storage. The system's $9,000 price placed it out of the mainstream personal computer marketplace, which was dominated by experimenters (affectionately referred to as *hackers*) who built low-cost kits ($500 or so) as a hobby. Obviously, the IBM system was not in competition for this low-cost market and did not sell as well by comparison.

The Model 5100 was succeeded by the 5110 and 5120 before IBM introduced what we know as the IBM Personal Computer (Model 5150). Although the 5100 series preceded the IBM PC, the older systems and the 5150 IBM PC had nothing in common. The PC IBM turned out was more closely related to the IBM System/23 DataMaster, an office computer system introduced in 1980. In fact, many of the engineers who developed the IBM PC had originally worked on the DataMaster.

In 1976, a new company called Apple Computer introduced the Apple I, which originally sold for $666.66. The selling price was an arbitrary number selected by one of Apple's cofounders, Steve Jobs. This system consisted of a main circuit board screwed to a piece of plywood; a case and power supply were not included. Only a few of these computers were made, and they reportedly have sold to collectors for more than $20,000. The Apple II, introduced in 1977, helped set the standard for nearly all the important microcomputers to follow, including the IBM PC.

The microcomputer world was dominated in 1980 by two types of computer systems. One type, the Apple II, claimed a large following of loyal users and a gigantic software base that was growing at a fantastic rate. The other type, CP/M systems, consisted not of a single system but of all the many systems that evolved from the original MITS Altair. These systems were compatible with one another and were distinguished by their use of the CP/M operating system and expansion slots, which followed the S-100 standard. All these systems were built by a variety of companies and sold under various names. For the most part, however, these systems used the same software and plug-in hardware. It is interesting to note that none of these systems was PC compatible or Macintosh compatible, the two primary standards in place today.

A new competitor looming on the horizon was able to see that to be successful, a personal computer needed to have an open architecture, slots for expansion, a modular design, and healthy support from both hardware and software companies other than the original manufacturer of the system. This competitor turned out to be IBM, which was quite surprising at the time because IBM was not known for systems with these open-architecture attributes! IBM, in essence, became more like the early Apple, and Apple itself became like everybody expected IBM to be. The open architecture of the forthcoming IBM PC and the closed architecture of the forthcoming Macintosh caused a complete turnaround in the industry.

The IBM Personal Computer

At the end of 1980, IBM decided to truly compete in the rapidly growing low-cost personal computer market. The company established the Entry Systems Division, located in Boca Raton, Florida, to develop the new system. The division was located intentionally far away from IBM's main headquarters in New York, or any other IBM facilities, so that this new division would be able to operate independently as a separate unit. This small group consisted of 12 engineers and designers under the direction of Don Estridge, and was charged with developing IBM's first real PC. (IBM considered the previous 5100 system, developed in 1975, to be an intelligent programmable terminal rather than a genuine computer, even though it truly was a computer.) Nearly all these engineers had come to the new division from the System/23 DataMaster project, which was a small office computer system introduced in 1980 and was the direct predecessor of the IBM PC.

Much of the PC's design was influenced by the DataMaster design. In the DataMaster's single-piece design, the display and keyboard were integrated into the unit. Because these features were limiting, they became external units on the PC, although the PC keyboard layout and electrical designs were copied from the DataMaster.

Several other parts of the IBM PC system also were copied from the DataMaster, including the expansion bus (or input/output slots), which included not only the same physical 62-pin connector, but also almost identical pin specifications. This copying of the bus design was possible because the PC used the same interrupt controller as the DataMaster and a similar direct memory access (DMA) controller. Also, expansion cards already designed for the DataMaster could easily be redesigned to function in the PC.

The DataMaster used an Intel 8085 CPU, which had a 64KB address limit and an 8-bit internal and external data bus. This arrangement prompted the PC design team to use the Intel 8088 CPU, which offered a much larger (1MB) memory address limit and an internal 16-bit data bus, but only an 8-bit external data bus. The 8-bit external data bus and similar instruction set enabled the 8088 to be easily interfaced into the earlier DataMaster designs.

IBM brought its system from idea to delivery of functioning systems in one year by using existing designs and purchasing as many components as possible from outside vendors. The Entry Systems Division was granted autonomy from IBM's other divisions and could tap resources outside the company, rather than go through the bureaucratic procedures that required exclusive use of IBM resources. IBM contracted out the PC's languages and operating system to a small company named Microsoft. That decision was the major factor in establishing Microsoft as the dominant force in PC software today.

Note

It is interesting to note that IBM had originally contacted Digital Research (the company that created CP/M, then the most popular personal computer operating system) to have it develop an operating system for the new IBM PC. However, Digital was leery of working with IBM and especially balked at the nondisclosure agreement IBM wanted Digital to sign. Microsoft jumped on the opportunity left open by Digital Research and, consequently, has become one of the largest software companies in the world. IBM's use of outside vendors in developing the PC was an open invitation for the aftermarket to jump in and support the system—and it did.

On Wednesday, August 12, 1981, a new standard was established in the microcomputer industry with the debut of the IBM PC. Since then, hundreds of millions of PC-compatible systems have been sold, as the original PC has grown into an enormous family of computers and peripherals. More software has been written for this computer family than for any other system on the market.

The PC Industry 20 Years Later

In the more than 20 years since the original IBM PC was introduced, many changes have occurred. The IBM-compatible computer, for example, advanced from a 4.77MHz 8088-based system to 1.5GHz or faster Pentium IV-based systems—nearly 12,000 times faster than the original IBM PC (in actual processing speed, not just clock speed). The original PC had only one or two single-sided floppy drives that stored 160KB each using DOS 1.0, whereas modern systems easily can have 75GB (75 billion bytes) or more of hard disk storage.

A rule of thumb in the computer industry (called Moore's Law, originally set forth by Intel cofounder Gordon Moore) is that available processor performance and disk-storage capacity doubles every two years, give or take.

Since the beginning of the PC industry, this pattern has held steady, and if anything, it may be accelerating.

In addition to performance and storage capacity, another major change since the original IBM PC was introduced is that IBM is not the only manufacturer of PC-compatible systems. IBM originated the PC-compatible standard, of course, but today it no longer sets the standards for the system it originated. More often than not, new standards in the PC industry are developed by companies and organizations other than IBM. Today, it is Intel and Microsoft who are primarily responsible for developing and extending the PC hardware and software standards, respectively. Some have even taken to calling PCs "Wintel" systems, owing to the dominance of those two companies.

In more recent years, Intel and Microsoft have carried the evolution of the PC forward. The introduction of hardware standards such as the PCI (Peripheral Component Interconnect) bus, AGP (Accelerated Graphics Port) bus, ATX and NLX motherboard form factors, processor socket and slot interfaces, and numerous others show that Intel is really pushing PC hardware design these days. In a similar fashion, Microsoft is pushing the software side of things with the continual evolution of the Windows operating system as well as applications such as the Office suite.

Today literally hundreds of system manufacturers follow the collective PC standard and produce computers that are fully PC compatible. In addition, thousands of peripheral manufacturers produce components that expand and enhance PC-compatible systems.

PC-compatible systems have thrived not only because compatible hardware can be assembled easily, but also because the primary operating system was available not from IBM but from a third party (Microsoft). The core of the system software is the BIOS (basic input/output system), and this was also available from third-party companies, such as AMI, Award, Phoenix, and others. This situation enabled other manufacturers to license the operating system and BIOS software and to sell their own compatible systems. The fact that DOS borrowed the functionality and user interface from both CP/M and UNIX probably had a lot to do with the amount of software that became available. Later, with the success of Windows, even more reasons would exist for software developers to write programs for PC-compatible systems.

One reason Apple Macintosh systems never enjoyed the extreme success of PC systems is that Apple controls all the primary systems software (BIOS and OS) and has never licensed it to other companies for use in compatible systems.

At some point in its development, Apple seemed to recognize this flawed stance, and in the mid-1990s, licensed its software to third-party manufacturers such as Power Computing. After a short time, though, Apple cancelled its licensing agreements with other manufacturers. Because Apple remains essentially a closed system, other companies cannot develop compatible machines, meaning Apple-compatible systems are available from only one source: Apple. As such, it seems too late for Apple to effectively compete with the PC-compatible juggernaut. It is fortunate for the computing public as a whole that IBM created a more open and extendible standard, which today finds systems being offered by hundreds of companies in thousands of configurations. This kind of competition among manufacturers and vendors of PC-compatible systems is the reason such systems offer so much performance and so many capabilities for the money.

The PC continues to thrive and prosper, and new technology continues to be integrated into these systems, enabling them to grow with the times. These systems offer a high value for the money and have plenty of software available to run on them. It's a safe bet that PC-compatible systems will dominate the personal computer marketplace for the next 15 to 20 years.

Moore's Law

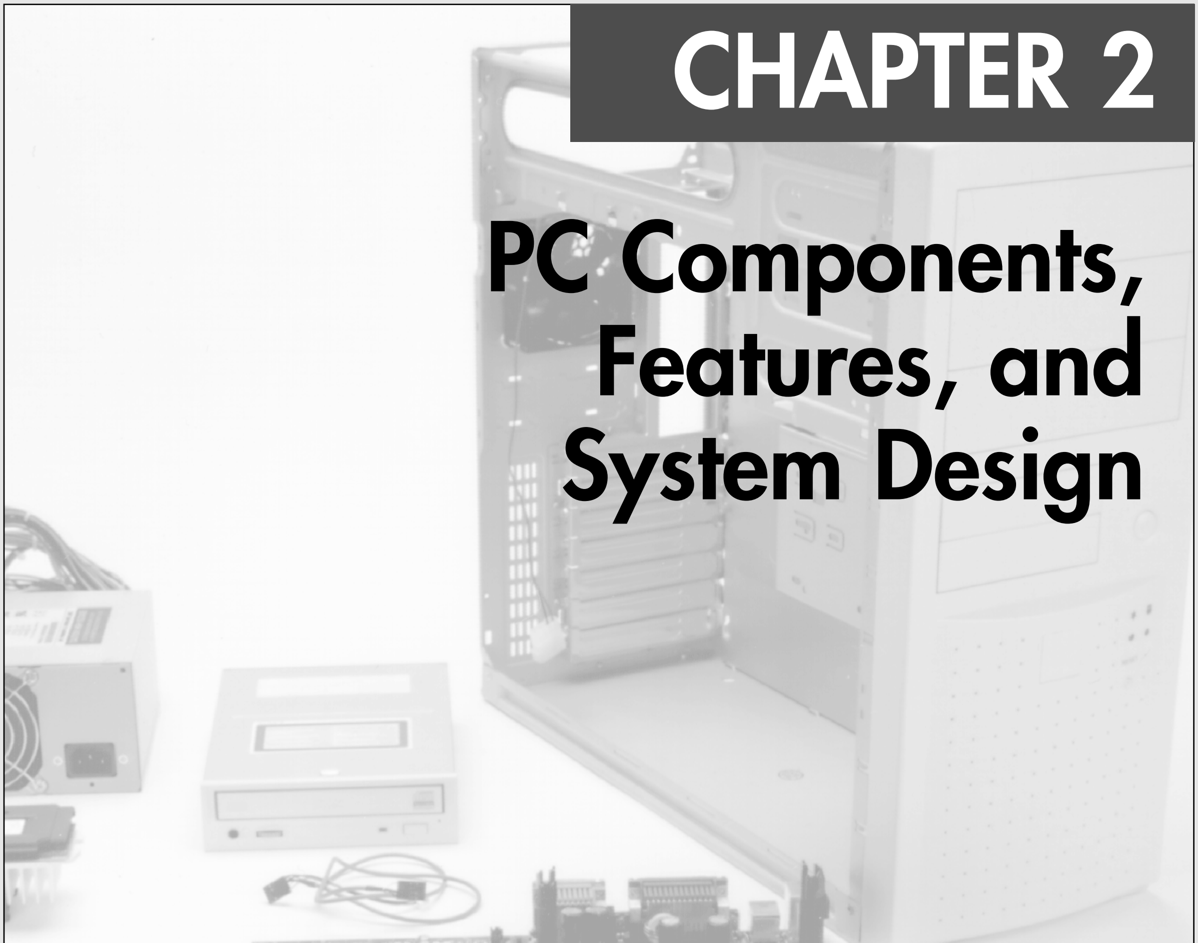
In 1965, Gordon Moore was preparing a speech about the growth trends in computer memory, and he made an interesting observation. When he began to graph the data, he realized a striking trend existed. Each new chip contained roughly twice as much capacity as its predecessor, and each chip was released within 18–24 months of the previous chip. If this trend continued, he reasoned, computing power would rise exponentially over relatively brief periods of time.

Moore's observation, now known as Moore's Law, described a trend that has continued to this day and is still remarkably accurate. It was found to not only describe memory chips, but also accurately describe the growth of processor power and disk-drive storage capacity. It has become the basis for many industry performance forecasts. In 28 years, the number of transistors on a chip has increased more than 12,000 times, from 2,300 on the 4004 in 1971 to more than 28.1 million on the Pentium III in 1999.

What does the future hold? For PCs, one thing is sure: They will continue to become faster, smaller, and cheaper. According to Gordon Moore, computing power continues to increase at a rate of about double the power every two years or less. This has held true not only for speed but for storage capacity as well. This means that computers you will purchase two years from now will be about twice as fast and store twice as much as what you can purchase today. The really amazing part is that this rapid pace of evolution shows no signs of letting up; in fact the pace might be increasing.

CHAPTER 2

PC Components, Features, and System Design



This chapter defines what a *PC* really is and continues by defining the types of PCs on the market. In addition, the chapter provides an overview of the components found in a modern PC. I'll also point you to sources (magazines, seminars, and online resources) that will help if you need to locate additional information. If you want to become A+ certified, you'll find the breakdown of test objectives at the end of this chapter to be a handy reference.

What Is a PC?

I normally ask the question, "What exactly is a PC?" when I begin one of my PC hardware seminars. Of course, most people immediately answer that PC stands for *personal computer*, which in fact it does. They might then continue by defining a personal computer as any small computer system purchased and used by an individual. Unfortunately, that definition is not nearly precise or accurate enough for our purposes. I agree that a PC is a personal computer, but not all personal computers are PCs. For example, an Apple Macintosh system is clearly a personal computer, but nobody I know would call a Mac a PC, least of all Mac users! For the true definition of what a PC is, you must look deeper.

Calling something a PC implies that it is something much more specific than just any personal computer. One thing it implies is a family relation to the first IBM PC from 1981. In fact, I'll go so far as to say that IBM literally *invented* the PC; that is, IBM designed and created the very first one, and IBM originally defined and set all the standards that made the PC distinctive from other personal computers. Note that it is very clear in my mind—as well as in the historical record—that IBM did *not* invent the personal computer. (Most recognize the historical origins of the personal computer in the MITS Altair, introduced in 1975.) IBM did not invent the personal computer, but it did invent the PC. Some people might take this definition a step further and define a PC as any personal computer that is "IBM compatible." In fact, many years back, PCs were called either IBM compatibles or IBM clones, in essence paying homage to the origins of the PC at IBM.

The reality today is that although IBM clearly designed and created the first PC in 1981 and controlled the development and evolution of the PC standard for several years thereafter, IBM is no longer in control of the PC standard; that is, it does not dictate what makes up a PC today. IBM lost control of the PC standard in 1987 when it introduced its PS/2 line of systems. Up until then, other companies that were producing PCs literally copied IBM's systems right down to the chips; connectors; and even the shapes (form factors) of the boards, cases, and power supplies. After 1987, IBM abandoned many of the standards it created in the first place. That's why for many years now I have refrained from using the designation "IBM compatible" when referring to PCs.

If a PC is no longer an IBM compatible, what is it? The real question seems to be, "Who is in control of the PC standard today?" That question is best broken down into two parts. First, who is in control of PC software? Second, who is in control of PC hardware?

Who Controls PC Software?

Most of the people in my seminars don't even hesitate for a split second when I ask this question; they immediately respond "Microsoft!" I don't think there is any argument with that answer. Microsoft clearly controls the operating systems used on PCs, which have migrated from the original MS-DOS to Windows 3.1/95/98/Me, Windows NT, and Windows 2000.

Microsoft has effectively used its control of the PC operating system as leverage to also control other types of PC software, such as utilities and applications. For example, many utility programs originally offered by independent companies, such as disk caching, disk compression, defragmentation, file structure repair, and even calculators and notepads, are now bundled in (included with) Windows. Microsoft has even bundled applications such as Web browsers, ensuring an automatic installed base for these applications—much to the dismay of companies who produce competing versions. Microsoft has also leveraged its control of the operating system to integrate its own networking software and applications suites more seamlessly into the operating system than others. That's why it now dominates most of the PC software universe, from operating systems to utilities, from word processors to spreadsheets.

In the early days of the PC, when IBM was clearly in control of the PC hardware standard, it hired Microsoft to provide most of the core software for the PC. IBM developed the hardware, wrote the BIOS (basic input/output system), and then hired Microsoft to develop the disk operating system (DOS), as well as several other programs and utilities for IBM. In what was later viewed as perhaps the most costly business mistake in history, IBM failed to secure exclusive rights to the DOS it had contracted from Microsoft, either by purchasing it outright or by an exclusive license agreement. Instead, IBM licensed it non-exclusively, which subsequently allowed Microsoft to sell the same MS-DOS code it developed for IBM to any other company that was interested. Early PC cloners such as Compaq eagerly licensed this same operating system code, and suddenly consumers could purchase the same basic MS-DOS operating system with several different company names on the box. In retrospect, that single contractual error made Microsoft into the dominant software company it is today, and subsequently caused IBM to lose control of the very PC standard it had created.

As a writer myself (of words, not software), I can appreciate what an incredible oversight this was. Imagine that a book publisher comes up with a great idea for a very popular book and then contracts with and subsequently pays an author to write it. Then, by virtue of a poorly written contract, the author discovers that the publisher can legally sell the very same book (perhaps with a different title) to all the competitors of the original publisher. Of course, no publisher I know would allow this to happen; yet that is exactly what IBM allowed Microsoft to do back in 1981. By virtue of its deal with Microsoft, IBM had essentially lost control of the software it commissioned for its new PC from day one.

It is interesting to note that in the PC business software enjoys copyright protection, whereas hardware can be protected only by patents, which are difficult, are time-consuming to get, and expire after 17 years. To patent something requires that it be a unique and substantially new design. This made it impossible to patent most aspects of the IBM PC because it was designed using previously existing parts that anybody could purchase off the shelf! In fact, most of the important parts for the original PC came from Intel, such as the 8088 processor, 8284 clock generator, 8253/54 timer, 8259 interrupt controller, 8237 DMA (direct memory access) controller, 8255 peripheral interface, and 8288 bus controller. These chips made up the heart and soul of the original PC.

Because the design of the original PC was not wholly patentable, anybody could duplicate the hardware of the IBM PC. All he or she had to do was purchase the same chips from the same manufacturers and suppliers IBM used and design a new motherboard with a similar circuit. Seemingly as if to aid in this, IBM even published complete schematic diagrams of its motherboards and all its adapter cards in very detailed and easily available technical reference manuals. I have several of these early IBM manuals and still refer to them from time to time for specific component-level PC design information. In fact, I still recommend these original manuals to anybody who wants to delve deeply into PC design.

The difficult part of copying the IBM PC was the software, which is protected by copyright law. Phoenix Software was among the first to develop a legal way around this problem, which enabled it to functionally duplicate (but not exactly copy) software such as the BIOS (basic input/output system). The *BIOS* is defined as the core set of control software, which drives the hardware devices in the system directly. These types of programs are normally called *device drivers*, so in essence, the BIOS is a collection of all the core device drivers used to operate and control the system hardware. What is called the *operating system* (such as DOS or Windows) uses the drivers in the BIOS to control and communicate with the various hardware and peripherals in the system.

▶▶ See Chapter 5, "BIOS," p. 345.

Phoenix's method for legally duplicating the BIOS was an ingenious form of reverse-engineering. It hired two teams of software engineers, the second of which had to be specially screened to consist only of people who had never seen or studied the IBM BIOS code. The first team did study the IBM BIOS and wrote as complete a description of what it did as possible. The second team read the description written by the first team and set out to write from scratch a new BIOS that did everything the first team described. The end result was a new BIOS written from scratch with code that, although not identical to IBM's, had exactly the same functionality.

Phoenix called this a "clean room" approach to reverse-engineering software, and it can escape any legal attack. Because IBM's original PC BIOS consisted of only 8KB of code and had limited functionality, duplicating it through the clean room approach was not very difficult nor time consuming. As the IBM BIOS evolved, Phoenix—as well as the other BIOS companies—found it relatively easy to keep up with any changes IBM made. Discounting the POST (power on self test) or BIOS Setup program (used for configuring the system) portion of the BIOS, most BIOSes—even today—have only about 32KB of active code. Today, Phoenix and others, such as AMI and Microid Research, are producing BIOS software for PC system manufacturers.

After the hardware and the BIOS of the IBM PC were duplicated, all that was needed to produce a fully IBM-compatible system was DOS. Reverse engineering DOS—even with the clean room approach—would have been a daunting task because DOS is much larger than the BIOS and consists of many more programs and functions. Also, the operating system has evolved and changed more often than the BIOS, which by comparison has remained relatively constant. This means that the only way to get DOS on an IBM compatible is to license it. This is where Microsoft comes in. Because IBM (who hired Microsoft to write DOS in the first place) did not ensure that Microsoft signed an exclusive license agreement, Microsoft was free to sell the same DOS to anybody. With a licensed copy of MS-DOS, the last piece was in place and the floodgates were open for IBM-compatible systems to be produced whether IBM liked it or not.

In retrospect, this is exactly why there are no clones or compatibles of the Apple Macintosh system. It is not that Mac systems cannot be duplicated; in fact, Mac hardware is fairly simple and easy to produce using off-the-shelf parts. The real problem is that Apple owns the Mac OS as well as the BIOS, and because Apple has seen fit not to license them, no other company can sell an Apple-compatible system. Also, note that the Mac BIOS and OS are very tightly integrated; the Mac BIOS is very large and complex, and it is essentially a part of the OS, unlike the much more simple and easily duplicated BIOS found on PCs. The greater complexity and integration has allowed both the Mac BIOS and OS to escape any clean-room duplication efforts. This means that without Apple's blessing (in the form of licensing), no Mac clones are likely ever to exist.

It might be interesting to note that during 1996–97, an effort was made by the more liberated thinkers at Apple to license its BIOS/OS combination, and several Mac-compatible machines were not only developed but also were produced and sold. Companies such as Sony, Power Computing, Radius, and even Motorola invested millions of dollars in developing these systems, but shortly after these first Mac clones were sold, Apple rudely canceled all licensing! This was apparently the result of an edict from Steve Jobs, who had been hired back to run the company and who was one of the original architects of the closed-box, proprietary-design Macintosh system in the first place. By canceling these licenses, Apple has virtually guaranteed that its systems will never be a mainstream success. Along with its smaller market share come much higher system costs, fewer available software applications, and fewer hardware upgrades as compared to PCs. The proprietary design also means that major repair or upgrade components, such as motherboards, power supplies, and cases, are available only from Apple at very high prices, and upgrades of these components are normally not cost effective.

I often think that if Apple had a different view and had licensed its OS and BIOS early on, this book might be called *Upgrading and Repairing Macs* instead!

Who Controls PC Hardware?

Although it is clear that Microsoft has always controlled PC software by virtue of its control over the PC operating system, what about the hardware? It is easy to see that IBM controlled the PC hardware standard up through 1987. After all, IBM invented the core PC motherboard design, expansion bus slot architecture (8/16-bit ISA bus), serial and parallel port design, video card design through VGA and XGA standards, floppy and hard disk interface and controller designs, power supply design, keyboard interface and design, mouse interface, and even the physical shapes (form factors) of everything from the motherboard to the expansion cards, power supplies, and system chassis. All these pre-1987 IBM PC, XT, and AT system design features are still influencing modern systems today.

But to me the real question is what company has been responsible for creating and inventing new and more recent PC hardware designs, interfaces, and standards? When I ask people that question, I normally see some hesitation in their responses—some people say Microsoft (but it controls the software, not the hardware), and some say Compaq or name a few other big-name system manufacturers. Only a few surmise the correct answer—Intel.

I can see why many people don't immediately realize this; I mean, how many people actually own an Intel-brand PC? No, not just one that says "Intel inside" on it (which refers only to the system having an Intel processor), but a system that was designed and built by, or even purchased through, Intel. Believe it or not, I think that many—if not most—people today do have Intel PCs!

Certainly this does not mean that consumers have purchased their systems from Intel because it is well known that Intel does not directly sell complete PCs to end users. You cannot currently order a system from Intel, nor can you purchase an Intel-brand system from somebody else. What I am talking about is the motherboard. In my opinion, the single most important part in a PC system is the motherboard, and I'd say that whoever made your motherboard should be considered the legitimate manufacturer of your system. Even back when IBM was the major supplier of PCs, it made only the motherboard and contracted the other components of the system (power supply, disk drives, and so on) out to others.

▶▶ See Chapter 4, "Motherboards and Buses," p. 193.

Most of the top-tier system manufacturers do make their own motherboards. According to *Computer Reseller News* magazine, the top desktop systems manufacturers for the last several years have consistently been Compaq, HP, and IBM. These companies, for the most part, do design and manufacture their own motherboards, as well as many other system components. In some cases, they even design their own chips and chipset components for their own boards. Although sales are high for these individual companies, a larger overall segment of the market can be called the second tier.

In this second tier are companies that do not really manufacture systems, but assemble them instead. That is, they purchase motherboards, cases, power supplies, disk drives, peripherals, and so on, and assemble and market the components together as complete systems. Dell, Gateway, and Micron are some of the larger system assemblers today, but hundreds more could be listed. In overall total volume, this ends up being the largest segment of the PC marketplace today. What is interesting about the second-tier systems is that, with very few exceptions, you and I can purchase the same motherboards and other components any of the second-tier manufacturers can (although we pay more than they do). We also can assemble a virtually identical system from scratch ourselves, but that is a story for Chapter 23, "Building or Upgrading Systems."

Note that some of these second-tier companies have incredible sales—for example, Dell is poised to take the top PC sales spot from Compaq, who has held it for many years. Gateway and the other system assemblers are not far behind.

The point of all this is, of course, that if Gateway, Dell, Micron, and others do not manufacture their own motherboards, who does? You guessed it—Intel. Not only do those specific companies use largely

Intel motherboards, if you check around, you'll find today that many of the systems on the market in the second tier come with Intel motherboards. The only place Intel doesn't dominate is the AMD-based systems using the Athlon or Duron.

Although this is an extreme case, one review of 10 systems in *Computer Shopper* magazine listed 8 out of the 10 systems evaluated as having Intel motherboards. In fact, those 8 used the exact same board. That means that those systems differed only in the cosmetics of the exterior case assemblies and by which peripheral components, such as video card, disk drives, keyboards, and so on, were selected. The funny thing was that many of the peripheral items were identical among the systems as well. Before you compare pre-assembled systems from different manufacturers, be sure to get a listing of which parts they are using; you might be surprised to see how similar the systems on the market today can be.

Although Intel still dominates motherboard sales, that dominance has faltered somewhat from a few years back. Because of Intel's focus on Rambus memory with many of its newer boards, many of the lower-cost system builders have been switching to alternative products. Also, Intel's boards are set up to make overclocking either impossible or extremely difficult, so "hotrod" system builders normally choose non-Intel boards.

▶▶ See "Chipsets," p. 225.

How did Intel come to dominate the interior of our PCs? Intel has been the dominant PC processor supplier since IBM chose the Intel 8088 CPU in the original IBM PC in 1981. By controlling the processor, Intel naturally controlled the chips needed to integrate its processors into system designs. This naturally led Intel into the chipset business. It started its chipset business in 1989 with the 82350 Extended Industry Standard Architecture (EISA) chipset, and by 1993 it had become—along with the debut of the Pentium processor—the largest-volume major motherboard chipset supplier. Now I imagine Intel sitting there, thinking that it makes the processor and all the other chips necessary to produce a motherboard, so why not just eliminate the middleman and make the entire motherboard, too? The answer to this, and a real turning point in the industry, came about in 1994 when Intel became the largest-volume motherboard manufacturer in the world. And Intel has remained solidly on top ever since. It doesn't just lead in this category by any small margin; in fact, during 1997, Intel made more motherboards than the next eight largest motherboard manufacturers combined, with sales of more than 30 million boards, worth more than $3.6 billion! Note that this figure does not include processors or chipsets—only the boards themselves. These boards end up in the various system assembler brand PCs you and I buy, meaning that most of us are now essentially purchasing Intel-manufactured systems, no matter who actually wielded the screwdriver.

Intel controls the PC hardware standard because it controls the PC motherboard. It not only makes the vast majority of motherboards being used in systems today, but it also supplies the vast majority of processors and motherboard chipsets to other motherboard manufacturers.

Intel also has had a hand in setting several recent PC hardware standards, such as the following:

- PCI (Peripheral Component Interconnect) local bus interface
- AGP (Accelerated Graphics Port) interface for high-performance video cards
- ATX motherboard, form factor that replaces the (somewhat long in the tooth) IBM-designed Baby-AT form factor that has been used since the early 1980s
- NLX motherboard form factor to replace the proprietary and limited LPX design used by many lower-cost systems, which finally brought motherboard upgradability to those systems
- DMI (Desktop Management Interface) for monitoring system hardware functions
- DPMA (Dynamic Power Management Architecture) and APM (Advanced Power Management) standards for managing power usage in the PC

Intel dominates not only the PC, but the entire semiconductor industry. According to the sales figures compiled by Cahners Research (shown in Figure 2.1), Intel has almost three times the sales of its closest competitor.

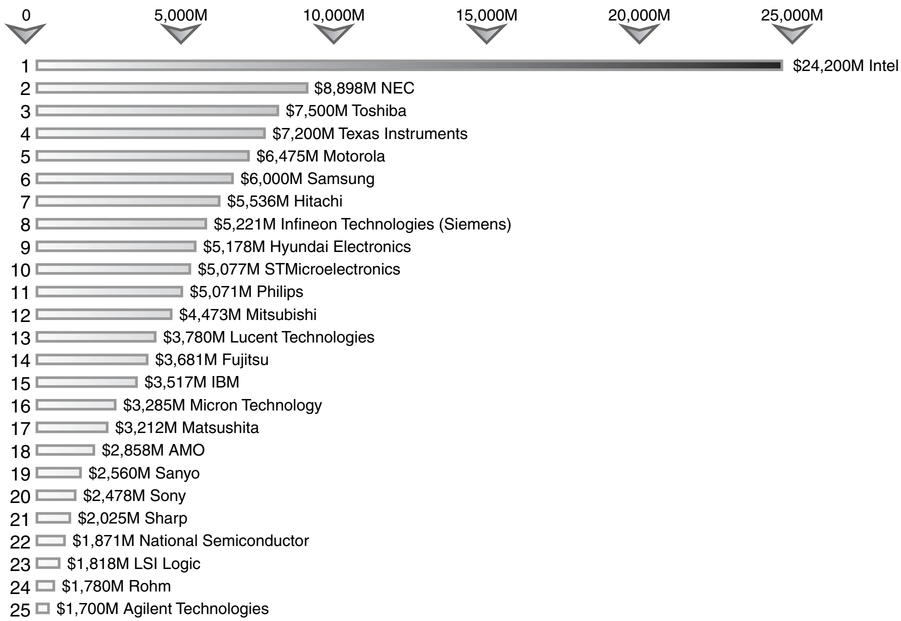


Figure 2.1 Top 25 companies ranked by 1999 semiconductor sales.

Whoever controls the operating system controls the software for the PC, and whoever controls the processor—and therefore the motherboard—controls the hardware. Because Microsoft and Intel together seem to control software and hardware in the PC today, it is no wonder the modern PC is often called a "Wintel" system.

PC 9x Specifications

Even though Intel fully controls PC hardware, Microsoft recognizes its power over the PC from the operating system perspective and has been releasing a series of documents called the "PC xx Design Guides" (where xx designates the year) as a set of standard specifications to guide both hardware and software developers who are creating products that work with Windows. The requirements in these guides are part of Microsoft's "Designed for Windows" logo requirement. In other words, if you produce either a hardware or software product and you want the official "Designed for Windows" logo to be on your box, your product must meet the PC xx minimum requirements.

Following are the documents that have been produced so far:

- "Hardware Design Guide for Microsoft Windows 95"
- "Hardware Design Guide Supplement for PC 95"
- "PC 97 Hardware Design Guide"
- "PC 98 System Design Guide"
- "PC 99 System Design Guide"
- "PC 2000 System Design Guide"

All these documents are available for download from Microsoft's Web site, and they also have been available as published books from Microsoft Press.

These system-design guides present information for engineers who build personal computers, expansion cards, and peripheral devices that are to be used with Windows 9x/Me, NT, and 2000 operating systems. The requirements and recommendations for PC design in these guides form the basis for the requirements of the "Designed for Windows" logo program for hardware Microsoft sponsors.

These guides include requirements for basic (desktop and mobile) systems, workstations, and even entertainment PCs. They also address Plug and Play device configuration and power management in PC systems; requirements for universal serial bus (USB) and IEEE 1394; and new devices supported under Windows, including new graphics and video device capabilities, DVD, scanners and digital cameras, and other devices.

Note

Note that these guides do not mean anything directly for the end user; instead, they are meant to be guides for PC manufacturers to build their systems. As such, they are only recommendations, and they do not have to be followed to the letter. In some ways, they are a market-control tool for Intel and Microsoft to further wield their influence over PC hardware and software. In reality, the market often dictates that some of these recommendations are disregarded, which is one reason why they continue to evolve with new versions year after year.

System Types

PCs can be broken down into many categories. I like to break them down in two ways—one by the type of software they can run, and the other by the motherboard host bus, or processor bus design and width. Because this book concentrates mainly on hardware, let's look at that first.

When a processor reads data, the data moves into the processor via the processor's external data bus connection. The processor's data bus is directly connected to the processor host bus on the motherboard. The processor data bus or host bus is also sometimes referred to as the *local bus* because it is local to the processor that is connected directly to it. Any other devices connected to the host bus essentially appear as if they are directly connected to the processor as well. If the processor has a 32-bit data bus, the motherboard must be wired to have a 32-bit processor host bus. This means the system can move 32 bits of data into or out of the processor in a single cycle.

▶▶ See "Data Bus," p. 58.

Different processors have different data bus widths, and the motherboards designed to accept them require a processor host bus with a matching width. Table 2.1 lists all the Intel processors and their data bus widths.

Table 2.1 Intel Processors and Their Data Bus Widths

Processor	Data Bus Width
8088	8-bit
8086	16-bit
286	16-bit
386SX	16-bit
386DX	32-bit
486/5x86	32-bit
Pentium (P5)/K6	64-bit

Table 2.1 Continued

Processor	Data Bus Width
Pentium Pro (P6)/Celeron/II/III	64-bit
AMD Duron/Athlon	64-bit
Pentium IV	64-bit

A common misconception arises in discussions of processor widths. Although the Pentium and newer processors all have 64-bit data bus widths, their internal registers are only 32 bits wide, and they process 32-bit commands and instructions. Thus, from a software point of view, all chips from the 386 to the Athlon/Duron and Pentium IV have 32-bit registers and execute 32-bit instructions. From the electronic or physical perspective, these 32-bit, software-capable processors have been available in physical forms with 16-bit (386SX), 32-bit (386DX and 486), and 64-bit (Pentium) data bus widths. The data bus width is the major factor in motherboard and memory system design because it dictates how many bits move in and out of the chip in one cycle.

▶▶ See "Internal Registers," p. 59.

The Itanium processor (code-named Merced) will have a new Intel architecture 64-bit (IA-64) instruction set, but it also will process the same 32-bit instructions as processors ranging from the 386 through the Pentium do, although we don't know how efficiently. It is not known whether Itanium will have a 64-bit data bus like the Pentium or will include a 128-bit data bus.

▶▶ See "Processor Specifications," p. 42.

Referring to Table 2.1, you can see that Pentium III systems have a 64-bit processor bus, which means any Pentium III motherboard has a 64-bit processor host bus. Pentium processors, whether they are the original Pentium, Pentium MMX, Pentium Pro, or even the Pentium II and III, all have 64-bit data busses.

As you can see from Table 2.1, systems can be broken down into the following hardware categories:

- 8-bit
- 16-bit
- 32-bit
- 64-bit

What is interesting is that besides the bus width, the 16- through 64-bit systems are remarkably similar in basic design and architecture. The older 8-bit systems are very different, however. This gives us two basic system types, or classes, of hardware:

- 8-bit (PC/XT-class) systems
- 16/32/64-bit (AT-class) systems

PC stands for personal computer; XT stands for an extended PC; and AT stands for an advanced technology PC. The terms *PC*, *XT*, and *AT*, as they are used here, are taken from the original IBM systems of those names. The XT was a PC system that included a hard disk for storage in addition to the floppy drives found in the basic PC system. These systems had an 8-bit 8088 processor and an 8-bit Industry Standard Architecture (ISA) bus for system expansion. The *bus* is the name given to expansion slots in which additional plug-in circuit boards can be installed. The 8-bit designation comes from the fact that the ISA bus found in the PC/XT class systems can send and receive only eight bits of data in a single cycle. The data in an 8-bit bus is sent along eight wires simultaneously, in parallel.

▶▶ See "The ISA Bus," p. 300.

16-bit and greater systems are said to be AT-class, which indicates that they follow certain standards and that they follow the basic design first set forth in the original IBM AT system. AT is the designation IBM applied to systems that first included more advanced 16-bit (and later, 32- and 64-bit) processors and expansion slots. AT-class systems must have a processor that is compatible with Intel 286 or higher processors (including the 386, 486, Pentium, Pentium Pro, Pentium II, and Pentium III processors), and they must have a 16-bit or greater system bus. The system bus architecture is central to the AT system design, along with the basic memory architecture, interrupt request (IRQ), direct memory access (DMA), and I/O port address design. All AT-class systems are similar in the way these resources are allocated and how they function.

The first AT-class systems had a 16-bit version of the ISA bus, which is an extension of the original 8-bit ISA bus found in the PC/XT-class systems. Eventually, several expansion slot or bus designs were developed for AT-class systems, including the following:

- 16-bit ISA bus
- 16/32-bit Extended ISA (EISA) bus
- 16/32-bit PS/2 Micro Channel Architecture (MCA) bus
- 16-bit PC-Card (PCMCIA) bus
- 32-bit Cardbus (PCMCIA) bus
- 32-bit VESA Local (VL) bus
- 32/64-bit Peripheral Component Interconnect (PCI) bus
- 32-bit Accelerated Graphics Port (AGP)

A system with any of these types of expansion slots is by definition an AT-class system, regardless of the actual Intel or Intel-compatible processor that is used. AT-type systems with 386 or higher processors have special capabilities not found in the first generation of 286-based ATs. These distinct capabilities are in the areas of memory addressing, memory management, and possible 32- or 64-bit wide access to data. Most systems with 386DX or higher chips also have 32-bit bus architectures to take full advantage of the 32-bit data transfer capabilities of the processor.

Most PC systems today incorporate 16-bit ISA slots for backward-compatibility and lower-function adapters, and PCI slots for truly high-performance adapters. In addition, most portable systems use PC-Card and Cardbus slots in the portable unit and ISA and PCI slots in optional docking stations.

Chapter 4, “Motherboards and Buses,” contains in-depth information on these and other PC system buses, including technical information such as pinouts, performance specifications, and bus operation and theory.

Table 2.2 summarizes the primary differences between the older 8-bit (PC/XT) systems and modern AT systems. This information distinguishes between these systems and includes all IBM and compatible models.

Table 2.2 Differences Between PC/XT and AT Systems

System Attributes	(8-Bit) PC/XT Type	(16/32/64-Bit) AT Type
Supported processors	All x86 or x88	286 or higher
Processor modes	Real	Real/Protected/Virtual Real
Software supported	16-bit only	16- or 32-bit
Bus slot width	8-bit	16/32/64-bit

Table 2.2 Continued

System Attributes	(8-Bit) PC/XT Type	(16/32/64-Bit) AT Type
Slot type	ISA only	ISA, EISA, MCA, PC-Card, Cardbus, VL-Bus, and PCI
Hardware interrupts	8 (6 usable)	16 (11 usable)
DMA channels	4 (3 usable)	8 (7 usable)
Maximum RAM	1MB	16MB/4GB or more
Floppy controller speed	250Kbps	250/300/500/1,000Kbps
Standard boot drive	360KB or 720KB	1.2MB/1.44MB/2.88MB
Keyboard interface	Unidirectional	Bidirectional
CMOS memory/clock	None standard	MC146818-compatible
Serial-port UART	8250B	16450/16550A

The easiest way to identify a PC/XT (8-bit) system is by the 8-bit ISA expansion slots. No matter which processor or other features the system has, if all the slots are 8-bit ISA, the system is a PC/XT. AT (16-bit plus) systems can be similarly identified—they have 16-bit or greater slots of any type. These can be ISA, EISA, MCA, PC-Card (formerly PCMCIA), Cardbus, VL-Bus, or PCI. Using this information, you can properly categorize virtually any system as a PC/XT type or an AT type. No PC/XT type (8-bit) systems have been manufactured for many years. Unless you are in a computer museum, virtually every system you encounter today is based on the AT-type design.

System Components

A modern PC is both simple and complicated. It is simple in the sense that over the years, many of the components used to construct a system have become integrated with other components into fewer and fewer actual parts. It is complicated in the sense that each part in a modern system performs many more functions than did the same types of parts in older systems.

This section briefly examines all the components and peripherals in a modern PC system. Each item is discussed further in later chapters.

Here are the components and peripherals necessary to assemble a basic modern PC system:

- Motherboard
- Processor
- Memory (RAM)
- Case/chassis
- Power supply
- Floppy drive
- Hard disk
- CD-ROM, CD-R, or DVD-ROM drive
- Keyboard
- Mouse
- Video card
- Monitor (display)
- Sound card
- Speakers
- Modem

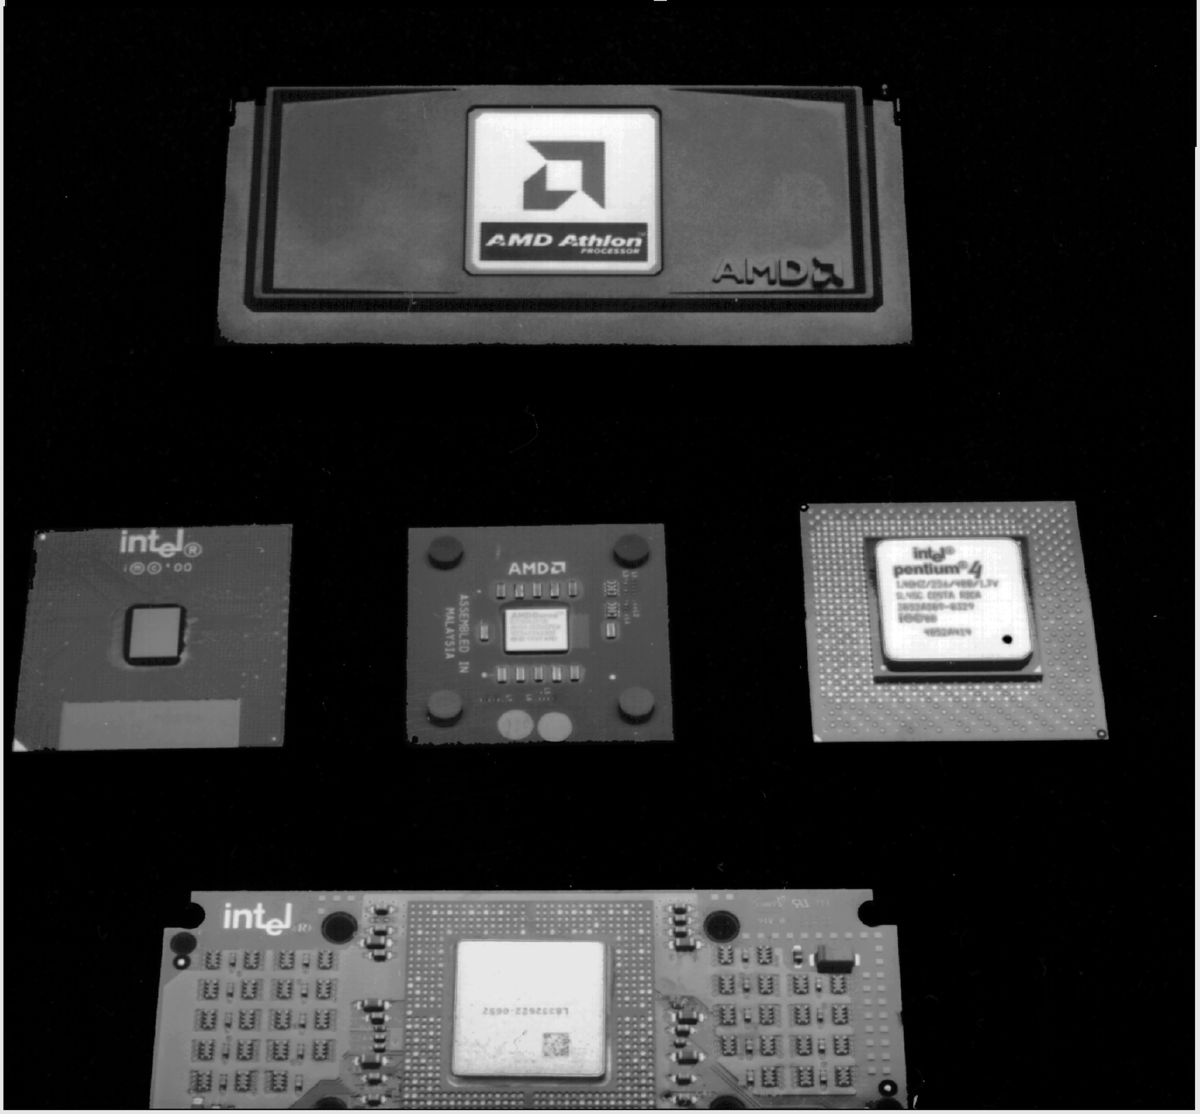
A breakdown of these items is shown in Table 2.3.

Table 2.3 Basic PC Components

Component	Description
Motherboard	The motherboard is the core of the system. It really is the PC; everything else is connected to it, and it controls everything in the system. Microprocessors are covered in detail in Chapter 3, "Microprocessor Types and Specifications."
Processor	The processor is often thought of as the "engine" of the computer. It's also called the CPU (central processing unit).
Memory (RAM)	The system memory is often called RAM (for random access memory). This is the primary memory, which holds all the programs and data the processor is using at a given time. Memory is covered in detail in Chapter 6, "Memory."
Case/chassis	The case is the frame or chassis that houses the motherboard, power supply, disk drives, adapter cards, and any other physical components in the system. The case is covered in detail in Chapter 21, "Power Supply and Chassis/Case."
Power supply	The power supply is what feeds electrical power to every single part in the PC. The power supply is covered in detail in Chapter 21.
Floppy drive	The floppy drive is a simple, inexpensive, low-capacity, removable-media, magnetic-storage device.
Hard drive	The hard disk is the primary archival storage memory for the system. Hard disk drives are also covered in detail in Chapter 10, "Hard Disk Storage."
CD-ROM/DVD-ROM	CD-ROM (compact disc read-only) and DVD-ROM (digital versatile disc read-only) drives are relatively high-capacity, removable media, optical drives. These drives are covered in detail in Chapter 13, "Optical Storage."
Keyboard	The keyboard is the primary device on a PC that is used by a human being to communicate with and control a system. Keyboards are covered in detail in Chapter 18, "Input Devices."
Mouse	Although many types of pointing devices are on the market today, the first and most popular device for this purpose is the mouse. The mouse and other pointing devices are covered in detail in Chapter 18.
Video card	The video card controls the information you see on the monitor. Video cards are covered in detail in Chapter 15, "Video Hardware."
Monitor	Monitors are covered in detail in Chapter 15.
Modem	Most prebuilt PCs ship with a modem (generally an internal modem). Modems and other Internet-connectivity devices and methods are covered in Chapter 19, "Internet Connectivity."

CHAPTER 3

Microprocessor Types and Specifications



Microprocessors

The brain or engine of the PC is the *processor* (sometimes called *microprocessor*), or *central processing unit (CPU)*. The CPU performs the system's calculating and processing. The processor is often the most expensive single component in the system; in higher-end systems it can cost up to four or more times more than the motherboard it plugs into. Intel is generally credited with creating the first microprocessor in 1971 with the introduction of a chip called the 4004. Today Intel still has control over the processor market, at least for PC systems. This means that all PC-compatible systems use either Intel processors or Intel-compatible processors from a handful of competitors (such as AMD or VIA/Cyrix).

Intel's dominance in the processor market hadn't always been assured. Although Intel is generally credited with inventing the processor and introducing the first one on the market, by the late 1970s the two most popular processors for PCs were *not* from Intel (although one was a clone of an Intel processor). Personal computers of that time primarily used the Z-80 by Zilog and the 6502 by MOS Technologies. The Z-80 was noted for being an improved and less expensive clone of the Intel 8080 processor, similar to the way companies today such as AMD, Cyrix, IDT, and Rise Technologies have cloned Intel's Pentium processors. In that case, though, the clone had become more popular than the original. Some might argue that AMD has achieved that type of status over the past year, but even though they have made significant gains, Intel still runs the PC processor show.

Back then I had a system containing both of those processors, consisting of a 1MHz (yes, that's *1*, as in 1MHz!) 6502-based Apple main system with a Microsoft Softcard (Z-80 card) plugged into one of the slots. The Softcard contained a 2MHz Z-80 processor. This enabled me to run software for both types of processors on the one system. The Z-80 was used in systems of the late 1970s and early 1980s that ran the CP/M operating system, whereas the 6502 was best known for its use in the early Apple computers (before the Mac).

The fate of both Intel and Microsoft was dramatically changed in 1981 when IBM introduced the IBM PC, which was based on a 4.77MHz Intel 8088 processor running the Microsoft Disk Operating System (MS-DOS) 1.0. Since that fateful decision was made, PC-compatible systems have used a string of Intel or Intel-compatible processors, with each new one capable of running the software of the processor before it—from the 8088 to the current Pentium 4/III/Celeron and Athlon/Duron. The following sections cover the various types of processor chips that have been used in personal computers since the first PC was introduced almost two decades ago. These sections provide a great deal of technical detail about these chips and explain why one type of CPU chip can do more work than another in a given period of time.

Pre-PC Microprocessor History

It is interesting to note that the microprocessor had existed for only 10 years prior to the creation of the PC! The microprocessor was invented by Intel in 1971; the PC was created by IBM in 1981. Now nearly 20 years later, we are still using systems based more or less on the design of that first PC. The processors powering our PCs today are still backward compatible in many ways with the 8088 selected by IBM in 1981.

The story of the development of the first microprocessor, the Intel 4004, can be read in Chapter 1, "Personal Computer Background." The 4004 processor was introduced on November 15, 1971, and originally ran at a clock speed of 108KHz (108,000 cycles per second, or just over one-tenth a megahertz). The 4004 contained 2,300 transistors and was built on a 10-micron process. This means that each line, trace, or transistor could be spaced about 10 microns (millionths of a meter) apart. Data was transferred 4 bits at a time, and the maximum addressable memory was only 640 bytes. The 4004 was designed for use in a calculator but proved to be useful for many other functions because of its inherent programmability.

In April 1972, Intel released the 8008 processor, which originally ran at a clock speed of 200KHz (0.2MHz). The 8008 processor contained 3,500 transistors and was built on the same 10-micron process as the previous processor. The big change in the 8008 was that it had an 8-bit data bus, which meant it could move data 8 bits at a time—twice as much as the previous chip. It could also address more memory, up to 16KB. This chip was primarily used in dumb terminals and general-purpose calculators.

The next chip in the lineup was the 8080, introduced in April 1974, running at a clock rate of 2MHz. Due mostly to the faster clock rate, the 8080 processor had 10 times the performance of the 8008. The 8080 chip contained 6,000 transistors and was built on a 6-micron process. Similar to the previous chip, the 8080 had an 8-bit data bus, so it could transfer 8 bits of data at a time. The 8080 could address up to 64KB of memory, significantly more than the previous chip.

It was the 8080 that helped start the PC revolution because this was the processor chip used in what is generally regarded as the first personal computer, the Altair 8800. The CP/M operating system was written for the 8080 chip, and Microsoft was founded and delivered its first product: Microsoft BASIC for the Altair. These initial tools provided the foundation for a revolution in software because thousands of programs were written to run on this platform.

In fact, the 8080 became so popular that it was cloned. A company called Zilog formed in late 1975, joined by several ex-Intel 8080 engineers. In July of 1976, it released the Z-80 processor, which was a vastly improved version of the 8080. It was not pin compatible but instead combined functions such as the memory interface and RAM refresh circuitry, which enabled cheaper and simpler systems to be designed. The Z-80 also incorporated a superset of 8080 instructions, meaning it could run all 8080 programs. It also included new instructions and new internal registers, so software designed for the Z-80 would not necessarily run on the older 8080. The Z-80 ran initially at 2.5MHz (later versions ran up to 10MHz) and contained 8,500 transistors. The Z-80 could access 64KB of memory.

Radio Shack selected the Z-80 for the TRS-80 Model 1, its first PC. The chip also was the first to be used by many pioneering systems, including the Osborne and Kaypro machines. Other companies followed, and soon the Z-80 was the standard processor for systems running the CP/M operating system and the popular software of the day.

Intel released the 8085, its followup to the 8080, in March of 1976. Even though it predated the Z-80 by several months, it never achieved the popularity of the Z-80 in personal computer systems. It was popular as an embedded controller, finding use in scales and other computerized equipment. The 8085 ran at 5MHz and contained 6,500 transistors. It was built on a 3-micron process and incorporated an 8-bit data bus.

Along different architectural lines, MOS Technologies introduced the 6502 in 1976. This chip was designed by several ex-Motorola engineers who had worked on Motorola's first processor, the 6800. The 6502 was an 8-bit processor like the 8080, but it sold for around $25, whereas the 8080 cost about $300 when it was introduced. The price appealed to Steve Wozniak, who placed the chip in his Apple I and Apple II designs. The chip was also used in systems by Commodore and other system manufacturers. The 6502 and its successors were also used in computer games, including the original Nintendo Entertainment System (NES) among others. Motorola went on to create the 68000 series, which became the basis for the Apple Macintosh line of computers. Today those systems use the PowerPC chip, also by Motorola and a successor to the 68000 series.

All these previous chips set the stage for the first PC chips. Intel introduced the 8086 in June 1978. The 8086 chip brought with it the original x86 instruction set that is still present on x86-compatible chips such as the Pentium 4. A dramatic improvement over the previous chips, the 8086 was a full 16-bit design with 16-bit internal registers and a 16-bit data bus. This meant that it could work on 16-bit numbers and data internally and also transfer 16 bits at a time in and out of the chip. The 8086 contained 29,000 transistors and initially ran at up to 5MHz. The chip also used 20-bit addressing, so it could directly address up to 1MB of memory. Although not directly backward compatible with the

8080, the 8086 instructions and language were very similar and enabled older programs to quickly be ported over to run. This later proved important to help jumpstart the PC software revolution with recycled CP/M (8080) software.

Although the 8086 was a great chip, it was expensive at the time and more importantly required an expensive 16-bit support chip and board design. To help bring costs down, in 1979, Intel released a crippled version of the 8086 called the 8088. The 8088 processor used the same internal core as the 8086, had the same 16-bit registers, and could address the same 1MB of memory, but the external data bus was reduced to 8 bits. This enabled support chips from the older 8-bit 8085 to be used, and far less expensive boards and systems could be made. It is for these reasons that IBM chose the crippled chip, the 8088, for the first PC.

This decision would affect history in several ways. The 8088 was fully software compatible with the 8086, so it could run 16-bit software. Also, because the instruction set was very similar to the previous 8085 and 8080, programs written for those older chips could be quickly and easily modified to run. This enabled a large library of programs to be quickly released for the IBM PC, thus helping it become a success. The overwhelming blockbuster success of the IBM PC left in its wake the legacy of requiring backward compatibility with it. To maintain the momentum, Intel has pretty much been forced to maintain backward compatibility with the 8088/8086 in most of the processors it has released since then.

In some ways the success of the PC, and the Intel architecture it contains, has limited the growth of the personal computer. In other ways, however, its success has caused a huge number of programs, peripherals, and accessories to be developed and the PC to become a de facto standard in the industry. The original 8088 processor used in the first PC contained close to 30,000 transistors and ran at less than 5MHz. Intel introduced one version of the Pentium III Xeon with 2MB of on-die cache that has a whopping 140 million transistors—the largest ever in a single processor chip. Intel has also released processors running at speeds of 2GHz and beyond, and AMD is not very far behind. And the progress doesn't stop there because, according to Moore's Law, processing speed and transistor counts are doubling every 1.5–2 years.

Processor Specifications

Many confusing specifications often are quoted in discussions of processors. The following sections discuss some of these specifications, including the data bus, address bus, and speed. The next section includes a table that lists the specifications of virtually all PC processors.

Processors can be identified by two main parameters: how wide they are and how fast they are. The speed of a processor is a fairly simple concept. Speed is counted in megahertz (MHz) and gigahertz (GHz), which means millions and billions, respectively, of cycles per second—and faster is better! The width of a processor is a little more complicated to discuss because three main specifications in a processor are expressed in width. They are

- Internal registers
- Data input and output bus
- Memory address bus

Systems below 16MHz usually had no cache memory at all. Starting with 16MHz systems, high-speed cache memory appeared on the motherboard because the main memory at the time could not run at 16MHz. Prior to the 486 processor, the cache on the motherboard was the only cache used in the system.

Starting with the 486 series, processors began including what was called Level 1 (L1) cache directly on the processor die. Therefore, the L1 cache always ran at the full speed of the chip, especially important when the later 486 chips began to run at speeds higher than the motherboards they were plugged into. During this time the cache on the motherboard was called the second level, or L2, cache and ran at the slower motherboard speed.

Starting with the Pentium Pro and Pentium II, Intel began including L2 cache memory chips directly within the same package as the main processor. Originally, this built-in L2 cache was implemented as physically separate chips contained within the processor package but not a part of the processor die. Because the speed of commercially available cache memory chips could not keep pace with the main processor, most of the L2 cache in these processors ran at one-half speed (Pentium II/III and AMD Athlon), whereas some ran the cache even slower—at two-fifths or even one-third the processor speed (AMD Athlon).

The original Pentium II, III, Celeron, and Athlon (Model 1 and 2) processors use 512KB of either one-half, two-fifths, or one-third speed L2 cache, as Table 3.1 shows.

Table 3.1 L2 Cache Speeds

Processor	Speed	L2 Size	L2 Type	L2 Speed
Pentium III	450–600MHz	512KB	External	1/2 core (225–300MHz)
Athlon	550–700MHz	512KB	External	1/2 core (275–350MHz)
Athlon	750–850MHz	512KB	External	2/5 core (300–340MHz)
Athlon	900–1000MHz	512KB	External	1/3 core (300–333MHz)

The Pentium Pro, Pentium II/III Xeon, newer Pentium III, Celeron, K6-3, Athlon (Model 4, code-named Thunderbird), and Duron processors include full-core speed L2, as shown in Table 3.2.

Table 3.2 Full-Core Speed Cache

Processor	Speed	L2 Size	L2 Type	L2 Speed
Pentium Pro	150–200MHz	256KB–1MB	External	Full core
K6-3	350–450MHz	256KB	On-die	Full core
Duron	550–700+MHz	64KB	On-die	Full core
Celeron	300–600+MHz	128KB	On-die	Full core
Pentium II Xeon	400–450MHz	512KB–2MB	External	Full core
Athlon	650–1000+MHz	256KB	On-die	Full core
Pentium III	500–1000+MHz	256KB	On-die	Full core
Pentium III Xeon	500–1000+MHz	256KB–2MB	On-die	Full core
Pentium 4	1.3–2.0+GHz	256KB	On-die	Full core
Xeon	1.4–2.0+GHz	256KB–1MB	On-die	Full core

The problem originally forcing the L2 cache to run at less than the processor core speed was simple: The cache chips available on the market simply couldn't keep up. Intel built its own high-speed cache memory chips for the earlier Xeon processors, but it also made them very expensive. A breakthrough occurred in the second-generation Celeron, in which Intel built both the L1 and L2 caches directly on the processor die, where they both ran at the full-core speed of the chip. This type of design was then quickly adopted by the second-generation Pentium III, as well as the AMD K6-3, Athlon, and Duron processors. In fact, virtually all future processors from Intel and AMD have adopted or will adopt on-die L2 cache because it is the only cost-effective way to include the L2 and increase the speed.

Table 3.3 lists the primary specifications for the Intel family of processors used in IBM and compatible PCs. Table 3.4 lists the Intel-compatible processors from AMD, Cyrix, NexGen, IDT, and Rise.

Table 3.3 Intel Processor Specifications

Processor	CPU Clock	Voltage	Internal Register Size	Data Bus Width	Max. Memory	Level 1 Cache
8088	1x	5v	16-bit	8-bit	1MB	—
8086	1x	5v	16-bit	16-bit	1MB	—
286	1x	5v	16-bit	16-bit	16MB	—

FPU = Floating-Point unit (internal math coprocessor)
WT = Write-Through cache (caches reads only)
WB = Write-Back cache (caches both reads and writes)
M = Millions
Bus = Processor external bus speed (motherboard speed)
Core = Processor internal core speed (CPU speed)
MMX = Multimedia extensions, 57 additional instructions for graphics and sound processing
3DNow = MMX plus 21 additional instructions for graphics and sound processing
Enh. 3DNow = 3DNow plus 24 additional instructions for graphics and sound processing

Note

Note in Table 3.3 that the Pentium Pro processor includes 256KB, 512KB, or 1MB of full-core speed L2 cache in a separate die within the chip. The Pentium II/III processors include 512KB of half-core speed L2 cache on the processor card. The Celeron, Pentium II PE, and Pentium IIIE processors include full-core speed L2 cache integrated directly within the processor die. The Celeron III uses the same die as the Pentium IIIE, but half of the on-die cache is disabled, leaving 128KB functional.

The transistor count figures do not include the external (off-die) 256KB, 512KB, 1MB, or 2MB L2 cache built into the Pentium Pro, Pentium II/III, Xeon, and AMD Athlon CPU packages, or the 2MB or 4MB of L3 cache in the Itanium. The external L2 cache in those processors contains an additional 15.5 (256KB), 31 (512KB), 62 million (1MB), or 124 million (2MB) transistors in separate chips, whereas the external 2MB or 4MB of L3 cache in the Itanium includes up to 300 million transistors!

Note in Table 3.4 that the Athlon includes either 512KB of L2 cache via separate chips, running at either one-half, two-fifths, or one-third the core speed, or 256KB of on-die L2 running at full-core speed, depending on which version you have.

L1 Cache Type	Level 2 Cache	L2 Cache Speed	Integral FPU	Multimedia Instructions	No. of Transistors	Date Introduced

WB	—	Bus	Yes	MMX	3.6M	Oct. '98

SSE = Streaming SIMD (single instruction multiple data) Extensions, MMX plus 70 additional instructions for graphics and sound processing

SSE2 = Streaming SIMD Extensions 2, SSE plus 144 additional instructions for graphics and sound processing

1. The 386SL contains an integral-cache controller, but the cache memory must be provided outside the chip.

2. Intel later marketed SL Enhanced versions of the SX, DX, and DX2 processors. These processors were available in both 5v and 3.3v versions and included power-management capabilities.

3. On-die integrated L2 cache—runs at full-core speed.

4. 128KB functional L2 cache (256KB total, 128KB disabled); uses same die as Pentium IIIE.

5. The Itanium also includes an additional 2MB (150M transistors) or 4MB (300M transistors) of integrated on-cartridge L3 cache running at full core speed.

Processor Speed Ratings

A common misunderstanding about processors is their different speed ratings. This section covers processor speed in general and then provides more specific information about Intel processors.

A computer system's clock speed is measured as a frequency, usually expressed as a number of cycles per second. A crystal oscillator controls clock speeds using a sliver of quartz sometimes contained in what looks like a small tin container. Newer systems include the oscillator circuitry in the motherboard chipset, so it might not be a visible separate component on newer boards. As voltage is applied to the quartz, it begins to vibrate (oscillate) at a harmonic rate dictated by the shape and size of the crystal (sliver). The oscillations emanate from the crystal in the form of a current that alternates at the harmonic rate of the crystal. This alternating current is the clock signal that forms the time base on which the computer operates. A typical computer system runs millions of these cycles per second, so speed is measured in megahertz. (One hertz is equal to one cycle per second.) An alternating current signal is like a sine wave, with the time between the peaks of each wave defining the frequency (see Figure 3.1).

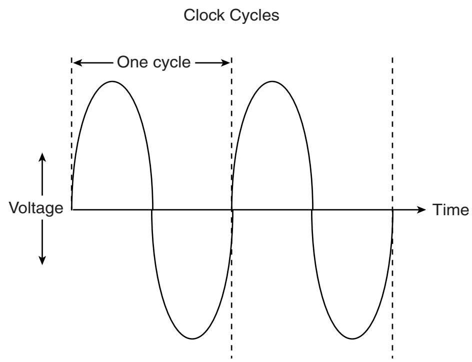

Figure 3.1 Alternating current signal showing clock cycle timing.

Note

The hertz was named for the German physicist Heinrich Rudolf Hertz. In 1885, Hertz confirmed the electromagnetic theory, which states that light is a form of electromagnetic radiation and is propagated as waves.

A single cycle is the smallest element of time for the processor. Every action requires at least one cycle and usually multiple cycles. To transfer data to and from memory, for example, a modern processor such as the Pentium III needs a minimum of three cycles to set up the first memory transfer and then only a single cycle per transfer for the next three to six consecutive transfers. The extra cycles on the first transfer typically are called *wait states*. A wait state is a clock tick in which nothing happens. This ensures that the processor isn't getting ahead of the rest of the computer.

▶▶ See "SIMMs, DIMMs, and RIMMs," p. 421.

The time required to execute instructions also varies:

- *8086 and 8088*. The original 8086 and 8088 processors take an average of 12 cycles to execute a single instruction.
- *286 and 386*. The 286 and 386 processors improve this rate to about 4.5 cycles per instruction.
- *486*. The 486 and most other fourth-generation Intel-compatible processors, such as the AMD 5x86, drop the rate further, to about 2 cycles per instruction.
- *Pentium, K6 series*. The Pentium architecture and other fifth-generation Intel-compatible processors, such as those from AMD and Cyrix, include twin instruction pipelines and other improvements that provide for operation at one or two instructions per cycle.
- *Pentium Pro, Pentium II/III/Celeron, and Athlon/Duron*. These P6 class processors, as well as other sixth-generation processors such as those from AMD and Cyrix, can execute as many as three or more instructions per cycle.

Different instruction execution times (in cycles) make comparing systems based purely on clock speed or number of cycles per second difficult. How can two processors that run at the same clock rate perform differently with one running "faster" than the other? The answer is simple: efficiency.

The main reason the 486 was considered fast relative to a 386 is that it executes twice as many instructions in the same number of cycles. The same thing is true for a Pentium; it executes about twice as many instructions in a given number of cycles as a 486. Therefore, given the same clock speed, a Pentium is twice as fast as a 486, and consequently a 133MHz 486 class processor (such as the AMD 5x86-133) is not even as fast as a 75MHz Pentium! That is because Pentium megahertz are "worth" about double what 486 megahertz are worth in terms of instructions completed per cycle. The Pentium II and III are about 50% faster than an equivalent Pentium at a given clock speed because they can execute about that many more instructions in the same number of cycles.

Comparing relative processor performance, you can see that a 1GHz Pentium III is about equal to a (theoretical) 1.5GHz Pentium, which is about equal to a 3GHz 486, which is about equal to a 6GHz 386 or 286, which is about equal to a 12GHz 8088. The original PC's 8088 ran at only 4.77MHz; today, we have systems that are comparatively at least 2,500 times faster! As you can see, you must be careful in comparing systems based on pure MHz alone because many other factors affect system performance.

Evaluating CPU performance can be tricky. CPUs with different internal architectures do things differently and can be relatively faster at certain things and slower at others. To fairly compare various CPUs at different clock speeds, Intel has devised a specific series of benchmarks called the *iCOMP (Intel Comparative Microprocessor Performance) index* that can be run against processors to produce a relative gauge of performance. The iCOMP index benchmark has been updated twice and released in original iCOMP, iCOMP 2.0, and now iCOMP 3.0 versions. More information on benchmarks, including iCOMP, can be found on Intel's site at `http://developer.intel.com/procs/perf/resources/spectrum.htm`.

Table 3.5 shows the relative power, or iCOMP 2.0 index, for several processors.

Note

Note that this reflects the most recent iCOMP index. Intel is designing new benchmarks that will show the power of the newer Pentium 4 and Itanium processor when running software optimized for their internal architectures.

Table 3.5 Intel iCOMP 2.0 Index Ratings

Processor	iCOMP 2.0 Index	Processor	iCOMP 2.0 Index
Pentium 75	67	Pentium Pro 200	220
Pentium 100	90	Celeron 300	226
Pentium 120	100	Pentium II 233	267
Pentium 133	111	Celeron 300A	296
Pentium 150	114	Pentium II 266	303
Pentium 166	127	Celeron 333	318
Pentium 200	142	Pentium II 300	332
Pentium-MMX 166	160	Pentium II Overdrive 300	351
Pentium Pro 150	168	Pentium II 333	366
Pentium-MMX 200	182	Pentium II 350	386
Pentium Pro 180	197	Pentium II Overdrive 333	387
Pentium-MMX 233	203	Pentium II 400	440
Celeron 266	213	Pentium II 450	483

The iCOMP 2.0 index is derived from several independent benchmarks and is a stable indication of relative processor performance. The benchmarks balance integer with floating-point and multimedia performance.

Recently, Intel discontinued the iCOMP 2.0 index and released the iCOMP 3.0 index. iCOMP 3.0 is an updated benchmark that incorporates an increasing use of 3D, multimedia, and Internet technology and software, as well as the increasing use of rich data streams and compute-intensive applications, including 3D, multimedia, and Internet technology. iCOMP 3.0 combines six benchmarks: WinTune 98 Advanced CPU Integer test, CPUmark 99, 3D WinBench 99-3D Lighting and Transformation Test, MultimediaMark 99, Jmark 2.0 Processor Test, and WinBench 99-FPU WinMark. These newer benchmarks take advantage of the SSE (Streaming SIMD Extensions), additional graphics and sound instructions built into the PIII. Without taking advantage of these new instructions, the PIII would benchmark at about the same speed as a PII at the same clock rate.

Table 3.6 shows the iCOMP Index 3.0 ratings for Pentium II and III processors.

Table 3.6 Intel iCOMP 3.0 Ratings

Processor	iCOMP 3.0 Index	Processor	iCOMP 3.0 Index
Pentium II 350	1000	Pentium III 650	2270
Pentium II 450	1240	Pentium III 700	2420
Pentium III 450	1500	Pentium III 750	2540
Pentium III 500	1650	Pentium III 800	2690
Pentium III 550	1780	Pentium III 866	2890
Pentium III 600	1930	Pentium III 1000	3280
Pentium III 600E	2110		

Considerations When Interpreting iCOMP Scores

Each processor's rating is calculated at the time the processor is introduced, using a particular, well-configured, commercially available system. Relative iCOMP index 3.0 scores and actual system performance might be affected by future changes in software design and configuration. Relative scores and actual system performance also can be affected by differences in components or characteristics of microprocessors, such as L2 cache, bus speed, extended multimedia or graphics instructions, or improvements in the microprocessor manufacturing process.

Differences in hardware components other than microprocessors used in the test systems also can affect how iCOMP scores relate to actual system performance. iCOMP 3.0 ratings cannot be compared with earlier versions of the iCOMP index because different benchmarks and weightings are used in calculating the result.

Processor Speeds and Markings Versus Motherboard Speed

Another confusing factor when comparing processor performance is that virtually all modern processors since the 486DX2 run at some multiple of the motherboard speed. For example, a Celeron 600 runs at a multiple of nine times the motherboard speed of 66MHz, whereas a Pentium III 1GHz runs at 7 1/2 times the motherboard speed of 133MHz. Up until early 1998, most motherboards ran at 66MHz or less because that is all Intel supported with its processors until then. Starting in April 1998, Intel released both processors and motherboard chipsets designed to run at 100MHz. Cyrix has a few processors designed to run on 75MHz motherboards, and many Pentium motherboards are capable of running that speed as well, although technically Intel never supported it. AMD also has versions of the K6-2 designed to run at motherboard speeds of 100MHz.

Starting in late 1999, chipsets and motherboards running at 133MHz became available to support the newer Pentium III processors. At that time, AMD Athlon motherboards and chipsets were introduced running at 100MHz but using a double transfer technique for an effective 200MHz data rate between the Athlon processor and the main chipset North Bridge chip.

In 2000 and 2001, processor bus speeds advanced further to 266MHz for the AMD Athlon and Intel Itanium and up to 400MHz for the Pentium 4.

Some might wonder why the more powerful Itanium processor uses a slower CPU bus than the Pentium 4. Actually, I wonder that as well! My guess is because they were designed by completely different teams with completely different agendas. The Itanium was designed in conjunction with HP, and from the get-go it was intended to use double-data rate (DDR) memory, which runs at 266MHz because that was favored by the server community. Because matching the CPU bus to the memory bus allows for the best performance, a system using DDR SDRAM works best if the CPU bus is also at 266MHz.

The P4, on the other hand, was designed to use RDRAM, hence the quad-pumped bus matching RDRAM in speed. Note that these bus speeds can easily be changed in the future, just as virtually every other processor that Intel has released can be. So, for example, I fully expect the Itanium to come out in a quad-pumped version using quad-data rate (QDR) memory when that technology becomes available. The bottom line is that nobody outside of the chip maker's inner circle really knows why some of these things come out the way they do!

Note

See Chapter 4, "Motherboards and Buses," for more information on chipsets and bus speeds.

Normally, you can set the motherboard speed and multiplier setting via jumpers or other configuration mechanism (such as BIOS setup) on the motherboard. Modern systems use a variable-frequency synthesizer circuit usually found in the main motherboard chipset to control the motherboard and CPU speed. Most Pentium motherboards have three or four speed settings. The processors used today are available in a variety of versions that run at different frequencies based on a given motherboard speed. For example, most of the Pentium chips run at a speed that is some multiple of the true motherboard speed. For example, Pentium processors and motherboards run at the speeds shown in Table 3.7.

Note

For information on specific AMD or Cyrix processors, see their respective sections later in this chapter.

Table 3.7 Intel Processor and Motherboard Speeds

CPU Type	CPU Speed (MHz/GHz)	CPU Clock Multiplier	Motherboard Speed (MHz)
Pentium	75	1.5x	50
Pentium	60	1x	60
Pentium	90	1.5x	60
Pentium	120	2x	60
Pentium	150	2.5x	60
Pentium/Pentium Pro	180	3x	60
Pentium	66	1x	66
Pentium	100	1.5x	66
Pentium	133	2x	66
Pentium/Pentium Pro	166	2.5x	66
Pentium/Pentium Pro	200	3x	66
Pentium/Pentium II	233	3.5x	66
Pentium(Mobile)/Pentium II/Celeron	266	4x	66

Table 3.7 Continued

CPU Type	CPU Speed (MHz/GHz)	CPU Clock Multiplier	Motherboard Speed (MHz)
Pentium II/Celeron	300	4.5x	66
Pentium II/Celeron	333	5x	66
Pentium II/Celeron	366	5.5x	66
Celeron	400	6x	66
Celeron	433	6.5x	66
Celeron	466	7x	66
Celeron	500	7.5x	66
Celeron	533	8x	66
Celeron	566	8.5x	66
Celeron	600	9x	66
Celeron	633	9.5x	66
Celeron	667	10x	66
Celeron	700	10.5x	66
Celeron	733	11x	66
Celeron	766	11.5x	66
Pentium II	350	3.5x	100
Pentium II	400	4x	100
Pentium II/III	450	4.5x	100
Pentium III	500	5x	100
Pentium III	550	5.5x	100
Pentium III	600	6x	100
Pentium III	650	6.5x	100
Pentium III	700	7x	100
Pentium III	750	7.5x	100
Pentium III/Celeron	800	8x	100
Pentium III/Celeron	850	8.5x	100
Pentium III	533	4x	133
Pentium III	600	4.5x	133
Pentium III	667	5x	133
Pentium III	733	5.5x	133
Pentium III	800	6x	133
Pentium III	866	6.5x	133
Pentium III	933	7x	133
Pentium III	1.0	7.5x	133
Pentium III	1.06	8x	133
Pentium III	1.13	8.5x	133
Pentium III	1.2	9x	133
Pentium III	1.26	9.5x	133
Pentium III	1.33	10x	133

Table 3.7 Continued

CPU Type	CPU Speed (MHz/GHz)	CPU Clock Multiplier	Motherboard Speed (MHz)
Pentium 4	1.3	3.25x	400
Pentium 4	1.4	3.5x	400
Pentium 4	1.5	3.75x	400
Pentium 4	1.6	4x	400
Pentium 4	1.7	4.25x	400
Pentium 4	1.8	4.5x	400
Pentium 4	1.9	4.75x	400
Pentium 4	2.0	5x	400
Pentium 4	2.1	5.25x	400
Itanium	733	2.75x	266
Itanium	800	3x	266

If all other variables are equal—including the type of processor, the number of wait states (empty cycles) added to different types of memory accesses, and the width of the data bus—you can compare two systems by their respective clock rates. However, the construction and design of the memory controller (contained in the motherboard chipset) as well as the type and amount of memory installed can have an enormous effect on a system's final execution speed.

In building a processor, a manufacturer tests it at various speeds, temperatures, and pressures. After the processor is tested, it receives a stamp indicating the maximum safe speed at which the unit will operate under the wide variation of temperatures and pressures encountered in normal operation. These ratings are clearly marked on the processor package.

Overclocking

In some systems, the processor speed can be set higher than the rating on the chip; this is called *overclocking* the chip. In many cases, you can get away with a certain amount of overclocking because Intel, AMD, and others often build safety margins into their ratings. So, a chip rated for, say, 800MHz might in fact run at 900MHz or more but is instead down-rated to allow for a greater margin of reliability. By overclocking, you are using this margin and running the chip closer to its true maximum speed. I don't normally recommend overclocking for a novice, but if you are comfortable with playing with your system, and you can afford and are capable of dealing with any potential consequences, overclocking might enable you to get more performance from your system.

If you are intent on overclocking, there are several issues to consider. One is that most Intel processors since the Pentium II have been multiplier-locked before they are shipped out. Therefore, any changes to the multiplier setting on the motherboard simply are ignored by the chip. Both Intel and AMD lock the multipliers on most of their newer processors. Although originally done to prevent re-markers from fraudulently relabeling processors, this has impacted the computing performance enthusiast, leaving tweaking the motherboard bus speed as the only way to achieve a clock speed higher than standard.

You can run into problems increasing motherboard bus speed as well. Intel motherboards, for example, simply don't support clock speeds other than the standard 66MHz, 100MHz, and 133MHz settings. Also all their boards with speed settings done via software (BIOS Setup) read the proper settings from the installed processor and only allow those settings. In other words, you simply plug in the processor, and the Intel motherboard won't allow any other settings other than what that processor is designed for.

Even if you could fool the processor into accepting a different setting, the jump from 66MHz to 100MHz, or from 100 to 133MHz, is a large one, and many processors would not make that much of a jump reliably. For example, a Pentium III 800E runs at a 100MHz bus speed with an 8x multiplier. Bumping the motherboard speed to 133MHz would cause the processor to try to run at 8×133 or 1066MHz. It is highly unlikely that the chip would run reliably at that speed. Likewise, a Celeron 600E runs at 9×66MHz. Raising the bus speed to 100MHz would cause the chip to try and run at 9×100MHz or 900MHz, likely an unsuccessful change.

What is needed is a board that supports intermediate speed settings and that allows the settings to be changed in smaller increments. This is because a given chip is generally overclockable by a certain percentage. The smaller steps you can take when increasing speed, the more likely that you'll be able to come close to the actual maximum speed of the chip without going over. For example, the Asus P3V4X motherboard supports front-side bus speed settings of 66MHz, 75MHz, 83MHz, 90MHz, 95MHz, 100MHz, 103MHz, 105MHz, 110MHz, 112MHz, 115MHz, 120MHz, 124MHz, 133MHz, 140MHz, and 150MHz. By setting the 800MHz Pentium IIIE to increments above 100MHz, you'd have:

Multiplier (fixed)	Bus Speed	Processor Speed
8x	100MHz	800MHz
8x	103MHz	824MHz
8x	105MHz	840MHz
8x	110MHz	880MHz
8x	112MHz	896MHz
8x	115MHz	920MHz
8x	120MHz	960MHz
8x	124MHz	992MHz
8x	133MHz	1066MHz

Likewise, using this motherboard with a Celeron 600, you could try settings above the standard 66MHz bus speed as follows:

Multiplier (fixed)	Bus Speed	Processor Speed
9x	66MHz	600MHz
9x	75MHz	675MHz
9x	83MHz	747MHz
9x	90MHz	810MHz
9x	95MHz	855MHz
9x	100MHz	900MHz

Typically, a 10%–20% increase is successful, so with this motherboard, you are likely to get your processor running 100MHz or more faster than it was originally designed for.

Another trick used by overclockers is to play with the voltage settings for the CPU. All Slot 1, Slot A, Socket 8, Socket 370, and Socket A processors have automatic voltage detection, where the system will detect and set the correct voltage by reading certain pins on the processor. Some motherboards, such as those made by Intel, do not allow any changes to these settings manually. Other motherboards, such as the Asus P3V4X I mentioned earlier, allow you to tweak the voltage settings from the automatic setting up or down by tenths of a volt. Some experimenters have found that by either increasing or decreasing voltage slightly from the standard, a higher speed of overclock can be achieved with the system running stable.

My recommendation is to be careful when playing with voltages. You can damage the chip in this manner. Even without changing voltage, overclocking with an adjustable bus speed motherboard is very easy and fairly rewarding. I do recommend you make sure you are using a high-quality board, good memory, and especially a good system chassis with additional cooling fans and a heavy-duty power supply. See Chapter 21, “Power Supply and Chassis/Case,” for more information on upgrading power supplies and chassis. Especially when overclocking, it is essential that the system components and especially the CPU remain properly cooled. Going a little bit overboard on the processor heatsink and adding extra cooling fans to the case never hurts and in many cases helps a great deal when hotrodding a system in this manner.

Note

One good source of online overclocking information is located at `http://www.tomshardware.com`. It includes, among other things, fairly thorough overclocking FAQs and an ongoing survey of users who have successfully (and sometimes unsuccessfully) overclocked their CPUs. Note that many of the newer Intel processors incorporate fixed bus multiplier ratios, which effectively prevent or certainly reduce the ability to overclock. Unfortunately, this can be overridden with a simple hardware fix, and many counterfeit processor vendors are selling re-marked (overclocked) chips.

The Processor Heatsink Might Hide the Rating

Most processors have heatsinks on top of them, which can prevent you from reading the rating printed on the chip.

A *heatsink* is a metal device that draws heat away from an electronic device. Most processors running at 50MHz and faster should have a heatsink installed to prevent the processor from overheating.

Fortunately, most CPU manufacturers are placing marks on the top and bottom of the processor. If the heatsink is difficult to remove from the chip, you can take the heatsink and chip out of the socket together and read the markings on the bottom of the processor to determine what you have.

Cyrix P-Ratings

Cyrix/IBM 6x86 processors use a PR (performance rating) scale that is not equal to the true clock speed in megahertz. For example, the Cyrix 6x86MX/MII-PR366 actually runs at only 250MHz (2.5 × 100MHz). This is a little misleading—you must set up the motherboard as if a 250MHz processor were being installed, not the 366MHz you might suspect. Unfortunately, this leads people to believe these systems are faster than they really are. Table 3.8 shows the relationship between the Cyrix 6x86, 6x86MX, and M-II P-Ratings versus the actual chip speeds in MHz.

Table 3.8 Cyrix P-Ratings Versus Actual Chip Speeds in MHz

CPU Type	P-Rating	Actual CPU Speed (MHz)	Clock Multiplier	Motherboard Speed (MHz)
6x86	PR90	80	2x	40
6x86	PR120	100	2x	50
6x86	PR133	110	2x	55
6x86	PR150	120	2x	60
6x86	PR166	133	2x	66
6x86	PR200	150	2x	75
6x86MX	PR133	100	2x	50

Table 3.8 Continued

CPU Type	P-Rating	Actual CPU Speed (MHz)	Clock Multiplier	Motherboard Speed (MHz)
6x86MX	PR133	110	2x	55
6x86MX	PR150	120	2x	60
6x86MX	PR150	125	2.5x	50
6x86MX	PR166	133	2x	66
6x86MX	PR166	137.5	2.5x	55
6x86MX	PR166	150	3x	50
6x86MX	PR166	150	2.5x	60
6x86MX	PR200	150	2x	75
6x86MX	PR200	165	3x	55
6x86MX	PR200	166	2.5x	66
6x86MX	PR200	180	3x	60
6x86MX	PR233	166	2x	83
6x86MX	PR233	187.5	2.5x	75
6x86MX	PR233	200	3x	66
6x86MX	PR266	207.5	2.5x	83
6x86MX	PR266	225	3x	75
6x86MX	PR266	233	3.5x	66
M-II	PR300	225	3x	75
M-II	PR300	233	3.5x	66
M-II	PR333	250	3x	83
M-II	PR366	250	2.5x	100
M-II	PR400	285	3x	95
M-II	PR433	300	3x	100
Cyrix III	PR433	350	3.5x	100
Cyrix III	PR466	366	3x	122
Cyrix III	PR500	400	3x	133
Cyrix III	PR533	433	3.5x	124
Cyrix III	PR533	450	4.5x	100

Note that a given P-Rating can mean several different actual CPU speeds—for example, a Cyrix 6x86MX-PR200 might actually be running at 150MHz, 165MHz, 166MHz, or 180MHz, but *not* at 200MHz.

This P-Rating is supposed to indicate speed in relation to an Intel Pentium processor, but the processor being compared to is the original non-MMX, small L1 cache version running on an older motherboard platform with an older chipset and slower technology memory. The P-Rating does not compare well against the Celeron, Pentium II, or Pentium III processors. In that case these chips are more comparative at their true speeds. In other words, the MII-PR366 really runs at only 250MHz and compares well against Intel processors running at closer to that speed. I consider calling a chip an MII-366 when it really runs at only 250MHz very misleading, to say the least.

AMD P-Ratings

Although both AMD and Cyrix concocted this misleading P-Rating system, AMD thankfully used it for only a short time and only on the older K5 processor. It still has the PR designation stamped on its newer chips, but all K6 and Athlon processors have PR numbers that match their actual CPU speeds in MHz. Table 3.9 shows the P-Rating and actual speeds of the AMD K5, K6, and Athlon processors.

Table 3.9 AMD P-Ratings Versus Actual Chip Speeds in MHz

CPU Type	P-Rating	Actual CPU Speed (MHz)	Clock Multiplier	Motherboard Speed (MHz)
K5	PR75	75	1.5x	50
K5	PR90	90	1.5x	60
K5	PR100	100	1.5x	66
K5	PR120	90	1.5x	60
K5	PR133	100	1.5x	66
K5	PR166	116.7	1.75x	66
K6	PR166	166	2.5x	66
K6	PR200	200	3x	66
K6	PR233	233	3.5x	66
K6	PR266	266	4x	66
K6	PR300	300	4.5x	66
K6-2	PR233	233	3.5x	66
K6-2	PR266	266	4x	66
K6-2	PR300	300	4.5x	66
K6-2	PR300	300	3x	100
K6-2	PR333	333	5x	66
K6-2	PR333	333	3.5x	95
K6-2	PR350	350	3.5x	100
K6-2	PR366	366	5.5x	66
K6-2	PR380	380	4x	95
K6-2	PR400	400	6x	66
K6-2	PR400	400	4x	100
K6-2	PR450	450	4.5x	100
K6-2	PR475	475	5x	95
K6-2	PR500	500	5x	100
K6-2	PR533	533	5.5x	97
K6-2	PR550	550	5.5x	100
K6-3	PR400	400	4x	100
K6-3	PR450	450	4.5x	100
Athlon	PR500	500	2.5x	200
Athlon	PR550	550	2.75x	200
Athlon/Duron	PR600	600	3x	200
Athlon/Duron	PR650	650	3.25x	200

Table 3.9 Continued

CPU Type	P-Rating	Actual CPU Speed (MHz)	Clock Multiplier	Motherboard Speed (MHz)
Athlon/Duron	PR700	700	3.5x	200
Athlon/Duron	PR750	750	3.75x	200
Athlon/Duron	PR800	800	4x	200
Athlon/Duron	PR850	850	4.25x	200
Athlon/Duron	PR900	900	4.5x	200
Athlon/Duron	PR950	950	4.75x	200
Athlon/Duron	PR1000	1.0	5x	200
Athlon	PR1100	1.1	5.5x	200
Athlon	PR1200	1.2	6x	200
Athlon	PR1300	1.3	6.5x	200
Athlon	PR1000	1.0	3.75x	266
Athlon	PR1133	1.13	4.25x	266
Athlon	PR1200	1.2	4.5x	266
Athlon	PR1333	1.33	5x	266

Note the Athlon to North Bridge processor bus actually runs at a double (2x) transfer speed, which is twice that of actual the motherboard clock speed.

Data Bus

Perhaps the most common way to describe a processor is by the speed at which it runs and the width of the processor's external data bus. This defines the number of data bits that can be moved into or out of the processor in one cycle. A *bus* is a series of connections that carry common signals. Imagine running a pair of wires from one end of a building to another. If you connect a 110v AC power generator to the two wires at any point and place outlets at convenient locations along the wires, you have constructed a power bus. No matter into which outlet you plug the wires, you have access to the same signal, which in this example is 110v AC power. Any transmission medium that has more than one outlet at each end can be called a bus. A typical computer system has several internal and external buses.

The processor bus discussed most often is the external data bus—the bundle of wires (or pins) used to send and receive data. The more signals that can be sent at the same time, the more data can be transmitted in a specified interval and, therefore, the faster (and wider) the bus. A wider data bus is like having a highway with more lanes, which enables greater throughput.

Data in a computer is sent as digital information consisting of a time interval in which a single wire carries 5v to signal a 1 data bit, or 0v to signal a 0 data bit. The more wires you have, the more individual bits you can send in the same time interval. A chip such as the 286 or 386SX, which has 16 wires for transmitting and receiving such data, has a 16-bit data bus. A 32-bit chip, such as the 386DX and 486, has twice as many wires dedicated to simultaneous data transmission as a 16-bit chip; a 32-bit chip can send twice as much information in the same time interval as a 16-bit chip. Modern processors such as the Pentium series have 64-bit external data buses. This means that all processors from the Pentium to the Athlon, Pentium 4, or Itanium can transfer 64 bits of data at a time to and from the system memory.

A good way to understand this flow of information is to consider a highway and the traffic it carries. If a highway has only one lane for each direction of travel, only one car at a time can move in a certain direction. If you want to increase traffic flow, you can add another lane so that twice as many cars pass in a specified time. You can think of an 8-bit chip as being a single-lane highway because 1 byte flows through at a time. (One byte equals 8 individual bits.) The 16-bit chip, with 2 bytes flowing at a time, resembles a two-lane highway. You might have four lanes in each direction to move a large number of automobiles; this structure corresponds to a 32-bit data bus, which has the capability to move 4 bytes of information at a time. Taking this further, a 64-bit data bus is like having an 8-lane highway moving data in and out of the chip!

Just as you can describe a highway by its lane width, you can describe a chip by the width of its data bus. When you read an advertisement that describes a 32-bit or 64-bit computer system, the ad usually refers to the CPU's data bus. This number provides a rough idea of the chip's performance potential (and, therefore, the system).

Perhaps the most important ramification of the data bus in a chip is that the width of the data bus also defines the size of a bank of memory. So, a 32-bit processor, such as the 486 class chips, reads and writes memory 32 bits at a time. Pentium-class processors, including the Pentium III and Celeron, read and write memory 64 bits at a time. Because standard 72-pin single inline memory modules (SIMMs) are only 32 bits wide, they must be installed one at a time in most 486 class systems; they're installed two at a time in most Pentium class systems. Newer dual inline memory modules (DIMMs) are 64 bits wide, so they are installed one at a time in Pentium class systems. Each DIMM is equal to a complete bank of memory in Pentium systems, which makes system configuration easy because they can then be installed or removed one at a time.

▶▶ See "Memory Banks," p. 438.

Internal Registers (Internal Data Bus)

The size of the internal registers indicate how much information the processor can operate on at one time and how it moves data around internally within the chip. This is sometimes also referred to as the *internal data bus*. The register size is essentially the same as the internal data bus size. A *register* is a holding cell within the processor; for example, the processor can add numbers in two different registers, storing the result in a third register. The register size determines the size of data on which the processor can operate. The register size also describes the type of software or commands and instructions a chip can run. That is, processors with 32-bit internal registers can run 32-bit instructions that are processing 32-bit chunks of data, but processors with 16-bit registers cannot. Most advanced processors today—chips from the 386 to the Pentium 4—use 32-bit internal registers and can therefore run the same 32-bit operating systems and software. The new Itanium processor has 64-bit internal registers, which require new operating systems and software to fully utilize.

Some processors have an internal data bus (made up of data paths and storage units called registers) that is larger than the external data bus. The 8088 and 386SX are examples of this structure. Each chip has an internal data bus twice the width of the external bus. These designs, which sometimes are called h*ybrid designs*, usually are low-cost versions of a "pure" chip. The 386SX, for example, can pass data around internally with a full 32-bit register size; for communications with the outside world, however, the chip is restricted to a 16-bit-wide data path. This design enables a systems designer to build a lower-cost motherboard with a 16-bit bus design and still maintain software and instruction set compatibility with the full 32-bit 386.

Internal registers often are larger than the data bus, which means the chip requires two cycles to fill a register before the register can be operated on. For example, both the 386SX and 386DX have internal 32-bit registers, but the 386SX must "inhale" twice (figuratively) to fill them, whereas the 386DX can do the job in one "breath." The same thing would happen when the data is passed from the registers back out to the system bus.

The Pentium is an example of this type of design. All Pentiums have a 64-bit data bus and 32-bit registers—a structure that might seem to be a problem until you understand that the Pentium has two internal 32-bit pipelines for processing information. In many ways, the Pentium is like two 32-bit chips in one. The 64-bit data bus provides for very efficient filling of these multiple registers. Multiple pipelines are called *superscalar* architecture, which was introduced with the Pentium processor.

▶▶ See "Pentium Processors," p. 129.

More advanced sixth-generation processors, such as the Pentium Pro and Pentium II/III, have as many as six internal pipelines for executing instructions. Although some of these internal pipes are dedicated to special functions, these processors can still execute as many as three instructions in one clock cycle. The newest Itanium processor uses 10-stage parallel pipelines, which enable it to execute as many as 20 operations per clock cycle.

Address Bus

The address bus is the set of wires that carries the addressing information used to describe the memory location to which the data is being sent or from which the data is being retrieved. As with the data bus, each wire in an address bus carries a single bit of information. This single bit is a single digit in the address. The more wires (digits) used in calculating these addresses, the greater the total number of address locations. The size (or width) of the address bus indicates the maximum amount of RAM that a chip can address.

The highway analogy can be used to show how the address bus fits in. If the data bus is the highway and the size of the data bus is equivalent to the number of lanes, the address bus relates to the house number or street address. The size of the address bus is equivalent to the number of digits in the house address number. For example, if you live on a street in which the address is limited to a two-digit (base 10) number, no more than 100 distinct addresses (00–99) can exist for that street (10^2). Add another digit, and the number of available addresses increases to 1,000 (000–999), or 10^3.

Computers use the binary (base 2) numbering system, so a two-digit number provides only four unique addresses (00, 01, 10, and 11), calculated as 2^2. A three-digit number provides only eight addresses (000–111), which is 2^3. For example, the 8086 and 8088 processors use a 20-bit address bus that calculates as a maximum of 2^{20} or 1,048,576 bytes (1MB) of address locations. Table 3.10 describes the memory-addressing capabilities of processors.

Table 3.10 Processor Memory-Addressing Capabilities

Processor Family	Address Bus	Bytes	Kilobytes (KB)	Megabytes (MB)	Gigabytes (GB)	Terabytes (TB)
8088 8086	20-bit	1,048,576	1,024	1	—	—
286 386SX	24-bit	16,777,216	16,384	16	—	—
386DX 486 586	32-bit	4,294,967,296	4,194,304	4,096	4	—
686 786	36-bit	68,719,476,736	67,108,864	65,536	64	—
Itanium	44-bit	17,592,186,044,416	17,179,869,184	16,777,216	16,384	16

Note: The Pentium and AMD K6 are 586 (fifth-generation) processors. The Pentium Pro/II/III/Celeron and AMD Athlon/Duron are 686 (sixth-generation) processors, and the Pentium 4 is considered a 786 (seventh-generation) processor.

The data bus and address bus are independent, and chip designers can use whatever size they want for each. Usually, however, chips with larger data buses have larger address buses. The sizes of the buses can provide important information about a chip's relative power, measured in two important ways. The size of the data bus is an indication of the chip's information-moving capability, and the size of the address bus tells you how much memory the chip can handle.

Internal Level 1 Cache

All modern processors starting with the 486 family include an integrated L1 cache and controller. The integrated L1 cache size varies from processor to processor, starting at 8KB for the original 486DX and now up to 32KB, 64KB, or more in the latest processors.

Because L1 cache is always built into the processor die, it runs at the full-core speed of the processor internally. By full-core speed, I mean this cache runs at the higher clock multiplied internal processor speed rather than the external motherboard speed. This cache basically is an area of very fast memory built into the processor and is used to hold some of the current working set of code and data. Cache memory can be accessed with no wait states because it is running at the same speed as the processor core.

Using cache memory reduces a traditional system bottleneck because system RAM often is much slower than the CPU. This prevents the processor from having to wait for code and data from much slower main memory, therefore improving performance. Without the L1 cache, a processor frequently would be forced to wait until system memory caught up.

L1 cache is even more important in modern processors because it is often the only memory in the entire system that can truly keep up with the chip. Most modern processors are clock multiplied, which means they are running at a speed that is really a multiple of the motherboard into which they are plugged. The Pentium III 1GHz, for example, runs at a multiple of 7 1/2 times the true motherboard speed of 133MHz. Because the main memory is plugged into the motherboard, it can also run at only 133MHz maximum. The only 1GHz memory in such a system is the L1 and L2 caches built into the processor core. In this example, the Pentium III 1GHz processor has 32KB of integrated L1 cache in two separate 16KB blocks and 256KB of L2, all running at the full speed of the processor core.

▶▶ See "Memory Module Speed," p. 440.

If the data the processor wants is already in the internal cache, the CPU does not have to wait. If the data is not in the cache, the CPU must fetch it from the Level 2 cache or (in less sophisticated system designs) from the system bus, meaning main memory directly.

To understand the importance of cache, you need to know the relative speeds of processors and memory. The problem with this is that processor speed usually is expressed in MHz (millions of cycles per second), whereas memory speeds often are expressed in nanoseconds (billionths of a second per cycle).

Both are really time- or frequency-based measurements, and a chart comparing them can be found in Chapter 6, "Memory," Table 6.3. In this table, you will note that a 233MHz processor equates to 4.3 nanosecond cycling, which means you would need 4ns memory to keep pace with a 200MHz CPU. Also note that the motherboard of a 233MHz system typically runs at 66MHz, which corresponds to a speed of 15ns per cycle, and requires 15ns memory to keep pace. Finally note that 60ns main memory (common on many Pentium class systems) equates to a clock speed of approximately 16MHz. So in a typical Pentium 233 system, you have a processor running at 233MHz (4.3ns per cycle), a motherboard running at 66MHz (15ns per cycle), and main memory running at 16MHz (60ns per cycle).

How Cache Works

To learn how the L1 and L2 caches work, consider the following analogy.

This story involves a person (in this case you) eating food to act as the processor requesting and operating on data from memory. The kitchen where the food is prepared is the main memory (SIMM/DIMM) RAM. The cache controller is the waiter, and the L1 cache is the table at which you are seated. L2 cache is introduced as a food cart, which is positioned between your table and the kitchen.

Okay, here's the story. Say you start to eat at a particular restaurant every day at the same time. You come in, sit down, and order a hot dog. To keep this story proportionately accurate, let's say you normally eat at the rate of one bite (byte? <g>) every four seconds (233MHz = about 4ns cycling). It also takes 60 seconds for the kitchen to produce any given item that you order (60ns main memory).

So, when you first arrive, you sit down, order a hot dog, and you have to wait for 60 seconds for the food to be produced before you can begin eating. After the waiter brings the food, you start eating at your normal rate. Pretty quickly you finish the hot dog, so you call the waiter and order a hamburger. Again you wait 60 seconds while the hamburger is being produced. When it arrives, you again begin eating at full speed. After you finish the hamburger, you order a plate of fries. Again you wait, and after it is delivered 60 seconds later, you eat it at full speed. Finally, you decide to finish the meal and order cheesecake for dessert. After another 60-second wait, you can again eat dessert at full speed. Your overall eating experience consists of mostly a lot of waiting, followed by short bursts of actual eating at full speed.

After coming into the restaurant for two consecutive nights at exactly 6 p.m. and ordering the same items in the same order each time, on the third night the waiter begins to think; "I know this guy is going to be here at 6 p.m., order a hot dog, a hamburger, fries, and then cheesecake. Why don't I have these items prepared in advance and surprise him, maybe I'll get a big tip?" So you enter the restaurant and order a hot dog, and the waiter immediately puts it on your plate, with no waiting! You then proceed to finish the hot dog and right as you are about to request the hamburger, the waiter deposits one on your plate. The rest of the meal continues in the same fashion, and you eat the entire meal, taking a bite every four seconds, and never have to wait for the kitchen to prepare the food. Your overall eating experience this time consists of all eating, with no waiting for the food to be prepared, due primarily to the intelligence and thoughtfulness of your waiter.

This analogy exactly describes the function of the L1 cache in the processor. The L1 cache itself is the table that can contain one or more plates of food. Without a waiter, the space on the table is a simple food buffer. When stocked, you can eat until the buffer is empty, but nobody seems to be intelligently refilling it. The waiter is the cache controller who takes action and adds the intelligence to decide which dishes are to be placed on the table in advance of your needing them. Like the real cache controller, he uses his skills to literally guess which food you will require next, and if and when he guesses right, you never have to wait.

Let's now say on the fourth night you arrive exactly on time and start off with the usual hot dog. The waiter, by now really feeling confident, has the hot dog already prepared when you arrive, so there is no waiting.

Just as you finish the hot dog, and right as he is placing a hamburger on your plate, you say "Gee, I'd really like a bratwurst now; I didn't actually order this hamburger." The waiter guessed wrong, and the consequence is that this time you have to wait the full 60 seconds as the kitchen prepares your brat. This is known as a *cache miss*, in which the cache controller did not correctly fill the cache with the data the processor actually needed next. The result is waiting, or in the case of a sample 233MHz Pentium system, the system essentially throttles back to 16MHz (RAM speed) whenever a cache miss occurs. According to Intel, the L1 cache in most of its processors has approximately a 90% hit ratio.

This means that the cache has the correct data 90% of the time, and consequently the processor runs at full speed—233MHz in this example—90% of the time. However, 10% of the time the cache controller guesses wrong and the data has to be retrieved out of the significantly slower main memory, meaning the processor has to wait. This essentially throttles the system back to RAM speed, which in this example was 60ns or 16MHz.

In this analogy, the processor was 14 times faster than the main memory. Memory speeds have increased from 16MHz (60ns) to 266MHz (3.8ns), but processor speeds have also risen to 2GHz and beyond, so even in the latest systems, memory is still 7.5 or more times SLOWER than the processor. Cache is what makes up the difference.

The main feature of L1 cache is that it has always been integrated into the processor core, where it runs at the same speed as the core. This, combined with the hit ratio of 90% or greater, makes L1 cache very important for system performance.

Level 2 Cache

To mitigate the dramatic slowdown every time an L1 cache miss occurs, a secondary (L2) cache can be employed.

Using the restaurant analogy I used to explain L1 cache in the previous section, I'll equate the L2 cache to a cart of additional food items placed strategically such that the waiter can retrieve food from it in 15 seconds. In an actual Pentium class (Socket 7) system, the L2 cache is mounted on the motherboard, which means it runs at motherboard speed—66MHz, or 15ns in this example. Now, if you ask for an item the waiter did not bring in advance to your table, instead of making the long trek back to the kitchen to retrieve the food and bring it back to you 60 seconds later, he can first check the cart where he has placed additional items. If the requested item is there, he will return with it in only 15 seconds. The net effect in the real system is that instead of slowing down from 233MHz to 16MHz waiting for the data to come from the 60ns main memory, the data can instead be retrieved from the 15ns (66MHz) L2 cache. The effect is that the system slows down from 233MHz to 66MHz.

Just as with the L1 cache, most L2 caches have a hit ratio also in the 90% range; therefore, if you look at the system as a whole, 90% of the time it will be running at full speed (233MHz in this example) by retrieving data out of the L1 cache. Ten percent of the time it will slow down to retrieve the data from the L2 cache. Ninety percent of the time the processor goes to the L2 cache, the data will be in the L2, and 10% of that time it will have to go to the slow main memory to get the data because of an L2 cache miss. So, by combining both caches, our sample system runs at full processor speed 90% of the time (233MHz in this case), at motherboard speed 9% (90% of 10%) of the time (66MHz in this case), and at RAM speed about 1% (10% of 10%) of the time (16MHz in this case). You can clearly see the importance of both the L1 and L2 caches; without them the system uses main memory more often, which is significantly slower than the processor.

This brings up other interesting points. If you could spend money doubling the performance of either the main memory (RAM) or the L2 cache, which would you improve? Considering that main memory is used directly only about 1% of the time, if you doubled performance there, you would double the speed of your system only 1% of the time! That doesn't sound like enough of an improvement to justify much expense. On the other hand, if you doubled L2 cache performance, you would be doubling system performance 9% of the time, a much greater improvement overall. I'd much rather improve L2 than RAM performance.

The processor and system designers at Intel and AMD know this and have devised methods of improving the performance of L2 cache. In Pentium (P5) class systems, the L2 cache usually was found on the motherboard and had to therefore run at motherboard speed. Intel made the first dramatic improvement by migrating the L2 cache from the motherboard directly into the processor and initially running it at the same speed as the main processor. The cache chips were made by Intel and mounted next to the main processor die in a single chip housing. This proved too expensive, so with the Pentium II Intel began using cache chips from third-party suppliers such as Sony, Toshiba, NEC, Samsung, and others. Because these were supplied as complete packaged chips and not raw die, Intel mounted them on a circuit board alongside the processor. This is why the Pentium II was designed as a cartridge rather than what looked like a chip.

One problem was the speed of the available third-party cache chips. The fastest ones on the market were 3ns or higher, meaning 333MHz or less in speed. Because the processor was being driven in speed above that, in the Pentium II and initial Pentium III processors Intel had to run the L2 cache at half the processor speed because that is all the commercially available cache memory could handle. AMD followed suit with the Athlon processor, which had to drop L2 cache speed even further in some models to two-fifths or one-third the main CPU speed to keep the cache memory speed less than the 333MHz commercially available chips.

Then a breakthrough occurred, which first appeared in the Celeron processor 300A and above. These had 128KB of L2 cache, but no external chips were used. Instead, the L2 cache had been integrated directly into the processor core just like the L1. Consequently, both the L1 and L2 caches now would run at full processor speed, and more importantly scale up in speed as the processor speeds increased in the future. In the newer Pentium III, as well as all the Xeon and Celeron processors, the L2 cache runs at full processor core speed, which means there is no waiting or slowing down after an L1 cache miss. AMD also achieved full-core speed on-die cache in its later Athlon and Duron chips. Using on-die cache improves performance dramatically because the 9% of the time the system would be using the L2 it would now remain at full speed instead of slowing down to one-half or less the processor speed or, even worse, slow down to motherboard speed as in Socket 7 designs. Another benefit of on-die L2 cache is cost, which is less because now fewer parts are involved.

Let's revisit the restaurant analogy using a modern Pentium III 1GHz. You would now be taking a bite every one second (1GHz = 1ns cycling). The L1 cache would also be running at that speed, so you could eat anything on your table at that same rate (the table = L1 cache). The real jump in speed comes when you want something that isn't already on the table (L1 cache miss), in which case the waiter runs to the cart and returns nine out of ten times with the food you want in only one second (L2 speed = 1GHz or 1ns cycling). In this more modern system, you would run at 1GHz 99% of the time (L1 and L2 hit ratios combined) and slow down to RAM speed (wait for the kitchen) only 1% of the time as before. With faster memory running at 133MHz (7.5ns), you would have to wait only 7.5 seconds for the food to come from the kitchen. If only restaurant performance increased at the same rate processor performance has!

Cache Organization

The organization of the cache memory in the 486 and Pentium family is called a *four-way set associative cache*, which means that the cache memory is split into four blocks. Each block also is organized as 128 or 256 lines of 16 bytes each.

To understand how a four-way set associative cache works, consider a simple example. In the simplest cache design, the cache is set up as a single block into which you can load the contents of a corresponding block of main memory. This procedure is similar to using a bookmark to locate the current page of a book you are reading. If main memory equates to all the pages in the book, the bookmark indicates which pages are held in cache memory. This procedure works if the required data is located within the pages marked with the bookmark, but it does not work if you need to refer to a previously read page. In that case, the bookmark is of no use.

An alternative approach is to maintain multiple bookmarks to mark several parts of the book simultaneously. Additional hardware overhead is associated with having multiple bookmarks, and you also have to take time to check all the bookmarks to see which one marks the pages of data you need.

Each additional bookmark adds to the overhead but also increases your chance of finding the desired pages.

If you settle on marking four areas in the book, you have essentially constructed a four-way set associative cache. This technique splits the available cache memory into four blocks, each of which stores different lines of main memory. Multitasking environments, such as Windows, are good examples of environments in which the processor needs to operate on different areas of memory simultaneously and in which a four-way cache improves performance greatly.

The contents of the cache must always be in sync with the contents of main memory to ensure that the processor is working with current data. For this reason, the internal cache in the 486 family is a *write-through* cache. Write-through means that when the processor writes information out to the cache, that information is automatically written through to main memory as well.

By comparison, the Pentium and later chips have an internal write-back cache, which means that both reads and writes are cached, further improving performance. Even though the internal 486 cache is write-through, the system can employ an external write-back cache for increased performance. In addition, the 486 can buffer up to 4 bytes before actually storing the data in RAM, improving efficiency in case the memory bus is busy.

Another feature of improved cache designs is that they are nonblocking. This is a technique for reducing or hiding memory delays by exploiting the overlap of processor operations with data accesses. A *nonblocking* cache enables program execution to proceed concurrently with cache misses as long as certain dependency constraints are observed. In other words, the cache can handle a cache miss much better and enable the processor to continue doing something nondependent on the missing data.

The cache controller built into the processor also is responsible for watching the memory bus when alternative processors, known as *bus masters*, are in control of the system. This process of watching the bus is referred to as *bus snooping*. If a bus master device writes to an area of memory that also is stored in the processor cache currently, the cache contents and memory no longer agree. The cache controller then marks this data as invalid and reloads the cache during the next memory access, preserving the integrity of the system.

A secondary external L2 cache of extremely fast static RAM (SRAM) chips also is used in most systems. It further reduces the amount of time the CPU must spend waiting for data from system memory. The function of the secondary processor cache is similar to that of the onboard cache. The secondary processor cache holds information that is moving to the CPU, thereby reducing the time the CPU spends waiting and increasing the time the CPU spends performing calculations. Fetching information from the secondary processor cache rather than from system memory is much faster because of the SRAM chips' extremely fast speed—15 nanoseconds (ns) or less.

Pentium systems incorporate the secondary cache on the motherboard, whereas Pentium Pro and later systems have the secondary cache inside the processor package. By moving the L2 cache into the processor, systems are capable of running at speeds higher than the motherboard—up to as fast as the processor core.

As clock speeds increase, cycle time decreases. Most SIMM memory used in Pentium and earlier systems was 60ns, which works out to be only about 16MHz! Standard motherboard speeds are now 66MHz, 100MHz, or 133MHz, and processors are available at 600MHz or more. Newer systems don't use cache on the motherboard any longer because the faster SDRAM or RDRAM used in modern Pentium Celeron/II/III systems can keep up with the motherboard speed. The trend today is toward integrating the L2 cache into the processor die just like the L1 cache. This enables the L2 to run at full-core speed because it is now a part of the core. Cache speed is always more important than size. The rule is that a smaller but faster cache is always better than a slower but bigger cache. Table 3.11 illustrates the need for and function of L1 (internal) and L2 (external) caches in modern systems.

Table 3.11 CPU Speeds Relative to Cache, SIMM/DIMM, and Motherboard

CPU Type	Pentium	Pentium Pro	Pentium II	Pentium II
CPU speed	233MHz	200MHz	333MHz	450MHz
L1 cache speed	4.3ns (233MHz)	5.0ns (200MHz)	3.0ns (333MHz)	2.2ns (450MHz)
L2 cache speed	15ns (66MHz)	5ns (200MHz)	6ns (166MHz)	4.4ns (225MHz)
Motherboard speed	66MHz	66MHz	66MHz	100MHz
RAM type	FPM/EDO	FPM/EDO	SDRAM	SDRAM
RAM speed	60ns (16MHz)	60ns (16MHz)	15ns (66MHz)	10ns (100MHz)
CPU Type	**AMD K6-2**	**AMD K6-3**	**Pentium III (Katmai)**	**AMD Athlon**
CPU speed	550MHz	450MHz	600MHz	800MHz
L1 cache speed	1.8ns (550MHz)	2.2ns (450MHz)	1.6ns (600MHz)	1.3ns (800MHz)
L2 cache speed	10ns (100MHz)	2.2ns (450MHz)	3.3ns (300MHz)	3.1ns (320MHz)
Motherboard speed	100MHz	100MHz	100MHz	200MHz
RAM type	SDRAM	SDRAM	SDRAM	SDRAM
RAM speed	10ns (100MHz)	10ns (100MHz)	10ns (100MHz)	10ns (100MHz)
CPU Type	**AMD Athlon**	**AMD Duron**	**AMD Athlon (Thunderbird)**	**Celeron**
CPU speed	1000MHz	800MHz	1000MHz	800MHz
L1 cache speed	1ns (1000MHz)	1.3ns (800MHz)	1ns (1000MHz)	1.3ns (800MHz)
L2 cache speed	3ns (333MHz)	1.3ns (800MHz)	1ns (1000MHz)	1.3ns (800MHz)
Motherboard speed	200MHz	200MHz	266MHz	100MHz
RAM type	SDRAM	SDRAM	DDR	SDRAM
RAM speed	10ns (100MHz)	10ns (100MHz)	3.8ns (266MHz)	10ns (100MHz)
CPU Type	**Pentium III (Coppermine)**	**Pentium 4**	**Itanium**	
CPU speed	1000MHz	1.7GHz	800MHz	
L1 cache speed	1ns (1000MHz)	0.6ns (1.7GHz)	1.3ns (800MHz)	
L2 cache speed	1ns (1000MHz)	0.6ns (1.7GHz)	1.3ns (800MHz)	
Motherboard speed	133MHz	400MHz	266MHz	
RAM type	SDRAM	RDRAM	DDR	
RAM speed	7.5ns (133MHz)	2.5ns (800MHz)	3.8ns (266MHz)	

Note: RDRAM technically runs at 800MHz, but the channel is only 16 bits wide, resulting in a bandwidth of 1.6GB/sec, which is equivalent to running 200MHz at the 64-bit width of the processor data bus.

The Celeron processors at 300MHz and faster as well as the Pentium III processors at 600MHz and faster have on-die L2 cache that runs at the full-core speed of the processor. Newer Athlon processors and all Duron processors have full-core speed on-die cache as well. The older Pentium II and III processors, as well as the older Athlons, use external L2 and run the cache at either one-half, two-fifths, or one-third of the core processor speed. As you can see, having two levels of cache between the very fast CPU and the much slower main memory helps minimize any wait states the processor might have to endure, especially those with the on-die L2. This enables the processor to keep working closer to its true speed.

Processor Modes

All Intel 32-bit and later processors, from the 386 on up, can run in several modes. Processor modes refer to the various operating environments and affect the instructions and capabilities of the chip. The processor mode controls how the processor sees and manages the system memory and the tasks that use it.

Three different modes of operation possible are

- Real mode (16-bit software)
- Protected mode (32-bit software)
- Virtual real mode (16-bit programs within a 32-bit environment)

Real Mode

The original IBM PC included an 8088 processor that could execute 16-bit instructions using 16-bit internal registers and could address only 1MB of memory using 20 address lines. All original PC software was created to work with this chip and was designed around the 16-bit instruction set and 1MB memory model. For example, DOS and all DOS software, Windows 1.x through 3.x, and all Windows 1.x through 3.x applications are written using 16-bit instructions. These 16-bit operating systems and applications are designed to run on an original 8088 processor.

◄◄ See "Internal Registers," p. 59.

◄◄ See "Address Bus," p. 60.

Later processors such as the 286 could also run the same 16-bit instructions as the original 8088, but much faster. In other words, the 286 was fully compatible with the original 8088 and could run all 16-bit software just the same as an 8088, but, of course, that software would run faster. The 16-bit instruction mode of the 8088 and 286 processors has become known as *real mode*. All software running in real mode must use only 16-bit instructions and live within the 20-bit (1MB) memory architecture it supports. Software of this type is usually single-tasking—only one program can run at a time. No built-in protection exists to keep one program from overwriting another program or even the operating system in memory, so if more than one program is running, one of them could bring the entire system to a crashing halt.

Protected (32-bit) Mode

Then came the 386, which was the PC industry's first 32-bit processor. This chip could run an entirely new 32-bit instruction set. To take full advantage of the 32-bit instruction set, a 32-bit operating system and a 32-bit application were required. This new 32-bit mode was referred to as *protected mode*, which alludes to the fact that software programs running in that mode are protected from overwriting one another in memory. Such protection helps make the system much more crash-proof because an errant program cannot very easily damage other programs or the operating system. In addition, a crashed program can be terminated, while the rest of the system continues to run unaffected.

Knowing that new operating systems and applications—which take advantage of the 32-bit protected mode—would take some time to develop, Intel wisely built a backward-compatible real mode into the 386. That enabled it to run unmodified 16-bit operating systems and applications. It ran them quite well—much more quickly than any previous chip. For most people, that was enough; they did not necessarily want any new 32-bit software—they just wanted their existing 16-bit software to run more quickly. Unfortunately, that meant the chip was never running in the 32-bit protected mode, and all the features of that capability were being ignored.

When a high-powered processor such as a Pentium III is running DOS (real mode), it acts like a "Turbo 8088." Turbo 8088 means that the processor has the advantage of speed in running any 16-bit programs; it otherwise can use only the 16-bit instructions and access memory within the same 1MB memory map of the original 8088. Therefore, if you have a 128MB Pentium III system running Windows 3.x or DOS, you are effectively using only the first megabyte of memory, leaving the other 127MB largely unused!

New operating systems and applications that ran in the 32-bit protected mode of the modern processors were needed. Being stubborn, we resisted all the initial attempts at getting switched over to a 32-bit environment. It seems that as a user community, we are very resistant to change and would be content with our older software running faster rather than adopting new software with new features. I'll be the first one to admit that I was one of those stubborn users myself!

Because of this resistance, 32-bit operating systems, such as Unix or variants (such as Linux), OS/2, and even Windows NT and Windows 2000, have had a very hard time getting any mainstream share in the PC marketplace. Out of those, Windows 2000 is the only one that will likely become a true mainstream product, and that is mainly because Microsoft has coerced us in that direction with Windows 95 through 98 and Me. Windows 3.x was the last full 16-bit operating system. In fact, it was not a complete operating system because it ran on top of DOS.

Microsoft realized how stubborn the installed base of PC users was so it developed Windows 95 through the current Windows Me as a bridge to a full 32-bit world. Windows 95, 98, and Me are mostly 32-bit operating systems but retain enough 16-bit capability to fully run old 16-bit applications. Windows 95 came out in August 1995, a full 10 years later than the introduction of the first 32-bit PC processor! It has taken us only 10 years to migrate to software that can fully use the processors we have in front of us.

The new Itanium processor adds 64-bit native capability to the table. It also runs all the existing 32-bit software, but to fully take advantage of the processor, a 64-bit OS and applications are required. Microsoft has released 64-bit versions of Windows XP, and several companies have released 64-bit applications for networking and workstation use.

Virtual Real Mode

The key to the backward compatibility of the Windows 32-bit environment is the third mode in the processor: virtual real mode. *Virtual real* is essentially a virtual real mode 16-bit environment that runs inside 32-bit protected mode. When you run a DOS prompt window inside Windows, you have created a virtual real mode session. Because protected mode enables true multitasking, you can actually have several real mode sessions running, each with its own software running on a virtual PC. This can all run simultaneously, even while other 32-bit applications are running.

Note that any program running in a virtual real mode window can access up to only 1MB of memory, which that program will believe is the first and only megabyte of memory in the system. In other words, if you run a DOS application in a virtual real window, it will have a 640KB limitation on memory usage. That is because there is only 1MB of total RAM in a 16-bit environment, and the upper 384KB is reserved for system use. The virtual real window fully emulates an 8088 environment, so that aside from speed, the software runs as if it were on an original real mode-only PC. Each virtual machine gets its own 1MB address space, an image of the real hardware BIOS routines, and emulation of all other registers and features found in real mode.

Virtual real mode is used when you use a DOS window to run a DOS or Windows 3.x 16-bit program. When you start a DOS application, Windows creates a virtual DOS machine under which it can run.

One interesting thing to note is that all Intel and Intel-compatible (such as AMD and Cyrix) processors power up in real mode. If you load a 32-bit operating system, it automatically switches the processor into 32-bit mode and takes control from there.

Some 16-bit (DOS and Windows 3.x) applications misbehave, which means they do things that even virtual real mode does not support. Diagnostics software is a perfect example of this. Such software does not run properly in a real-mode (virtual real) window under Windows. In that case, you can still run your Pentium III in the original no-frills real mode by either booting to a DOS floppy or, in the case of Windows 9x (excluding Me), interrupting the boot process and commanding the system to boot plain DOS. This is accomplished on Windows 9x systems by pressing the F8 key when you see the prompt `Starting Windows...` on the screen or immediately after the beep when the power on self test (POST) is completed. In the latter case, it helps to press the F8 key multiple times because getting the timing just right is difficult and Windows 9x looks for the key during only a short two-second time window. If successful, you will then see the Startup menu; you can select one of the command prompt choices, which tell the system to boot plain 16-bit real mode DOS. The choice of Safe Mode Command Prompt is best if you are going to run true hardware diagnostics, which do not normally run in protected mode and should be run with a minimum of drivers and other software loaded.

Note that even though Windows Me is based on Windows 98, Microsoft removed the Startup menu option in an attempt to further wean us from any 16-bit operation. Windows NT and 2000 also lack the capability to interrupt the startup in this manner. For these operating systems, you need a Startup Disk (floppy), which you can create and then use to boot the system in real mode. Normally, you would do this to perform certain maintenance procedures, especially such as running hardware diagnostics or doing direct disk sector editing.

Although real mode is used by 16-bit DOS and “standard” DOS applications, special programs were available that “extend” DOS and allow access to extended memory (over 1MB). These are sometimes called *DOS extenders* and usually are included as a part of any DOS or Windows 3.x software that uses them. The protocol that describes how to make DOS work in protected mode is called DOS protected mode interface (DPMI). DPMI was used by Windows 3.x to access extended memory for use with Windows 3.x applications. It allowed these programs to use more memory even though they were still 16-bit programs. DOS extenders are especially popular in DOS games because they enable them to access much more of the system memory than the standard 1MB most real mode programs can address. These DOS extenders work by switching the processor in and out of real mode. In the case of those that run under Windows, they use the DPMI interface built into Windows, enabling them to share a portion of the system’s extended memory.

Another exception in real mode is that the first 64KB of extended memory is actually accessible to the PC in real mode, despite the fact that it’s not supposed to be possible. This is the result of a bug in the original IBM AT with respect to the 21st memory address line, known as A20 (A0 is the first address line). By manipulating the A20 line, real-mode software can gain access to the first 64KB of extended memory—the first 64KB of memory past the first megabyte. This area of memory is called the *high memory area (HMA)*.

SMM (Power Management)

Spurred on primarily by the goal of putting faster and more powerful processors in laptop computers, Intel has created power-management circuitry. This circuitry enables processors to conserve energy use and lengthen battery life. This was introduced initially in the Intel 486SL processor, which is an enhanced version of the 486DX processor. Subsequently, the power-management features were universalized and incorporated into all Pentium and later processors. This feature set is called SMM, which stands for *system management mode*.

SMM circuitry is integrated into the physical chip but operates independently to control the processor’s power use based on its activity level. It enables the user to specify time intervals after which the CPU will be partially or fully powered down. It also supports the Suspend/Resume feature that allows for instant power on and power off, used mostly with laptop PCs. These settings usually are controlled via system BIOS settings.

Superscalar Execution

The fifth-generation Pentium and newer processors feature multiple internal instruction execution pipelines, which enable them to execute multiple instructions at the same time. The 486 and all preceding chips can perform only a single instruction at a time. Intel calls the capability to execute more than one instruction at a time *superscalar* technology. This technology provides additional performance compared with the 486.

▶▶ See "Pentium Processors," p. 129.

Superscalar architecture usually is associated with high-output Reduced Instruction Set Computer (RISC) chips. A RISC chip has a less complicated instruction set with fewer and simpler instructions. Although each instruction accomplishes less, overall the clock speed can be higher, which can usually increase performance. The Pentium is one of the first Complex Instruction Set Computer (CISC) chips to be considered superscalar. A CISC chip uses a richer, fuller-featured instruction set, which has more complicated instructions. As an example, say you wanted to instruct a robot to screw in a light bulb. Using CISC instructions you would say

1. Pick up the bulb.
2. Insert it into the socket.
3. Rotate clockwise until tight.

Using RISC instructions, you would say something more along the lines of

1. Lower hand.
2. Grasp bulb.
3. Raise hand.
4. Insert bulb into socket.
5. Rotate clockwise one turn.
6. Is bulb tight? If not repeat step 5.
7. End.

Overall, many more RISC instructions are required to do the job because each instruction is simpler (reduced) and does less. The advantage is that there are fewer overall commands the robot (or processor) has to deal with, and it can execute the individual commands more quickly, and thus in many cases execute the complete task (or program) more quickly as well. The debate goes on whether RISC or CISC is really better, but in reality there is no such thing as a pure RISC or CISC chip—it is all just a matter of definition, and the lines are somewhat arbitrary.

Intel and compatible processors have generally been regarded as CISC chips, although the fifth- and sixth-generation versions have many RISC attributes and internally break CISC instructions down into RISC versions.

MMX Technology

MMX technology was originally named for multimedia extensions, or matrix math extensions, depending on whom you ask. Intel officially states that it is actually not an abbreviation and stands for nothing other than the letters MMX (not being an abbreviation was apparently required so that the letters could be trademarked); however, the internal origins are probably one of the preceding.

MMX technology was introduced in the later fifth-generation Pentium processors (see Figure 3.2) as a kind of add-on that improves video compression/decompression, image manipulation, encryption, and I/O processing—all of which are used in a variety of today's software.

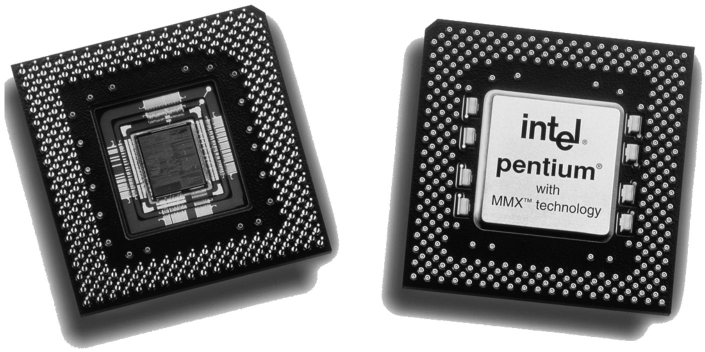

Figure 3.2 An Intel Pentium MMX chip shown from the top and bottom (exposing the die). *Photograph used by permission of Intel Corporation.*

MMX consists of two main processor architectural improvements. The first is very basic; all MMX chips have a larger internal L1 cache than their non-MMX counterparts. This improves the performance of any and all software running on the chip, regardless of whether it actually uses the MMX-specific instructions.

The other part of MMX is that it extends the processor instruction set with 57 new commands or instructions, as well as a new instruction capability called single instruction, multiple data (SIMD).

Modern multimedia and communication applications often use repetitive loops that, while occupying 10% or less of the overall application code, can account for up to 90% of the execution time. SIMD enables one instruction to perform the same function on multiple pieces of data, similar to a teacher telling an entire class to "sit down," rather than addressing each student one at a time. SIMD enables the chip to reduce processor-intensive loops common with video, audio, graphics, and animation.

Intel also added 57 new instructions specifically designed to manipulate and process video, audio, and graphical data more efficiently. These instructions are oriented to the *highly parallel* and often repetitive sequences often found in multimedia operations. Highly parallel refers to the fact that the same processing is done on many data points, such as when modifying a graphic image. The main drawbacks to MMX were that it worked only on integer values and used the floating-point unit for processing, so time was lost when a shift to floating-point operations was necessary. These drawbacks were corrected in the additions to MMX from Intel and AMD.

Intel licensed the MMX capabilities to competitors such as AMD and Cyrix, who were then able to upgrade their own Intel-compatible processors with MMX technology.

SSE and SSE2

In February 1999, Intel introduced the Pentium III processor, and included in that processor was an update to MMX called Streaming SIMD Extensions (SSE). These were also called Katmai New Instructions (KNI) up until their debut because they were originally included on the Katmai processor, which was the codename for the Pentium III. The Celeron 533A and faster Celeron processors based on the Pentium III core also support SSE instructions. The earlier Pentium II and Celeron 533 and lower (based on the Pentium II core) do not support SSE.

SSE includes 70 new instructions for graphics and sound processing over what MMX provided. SSE is similar to MMX; in fact, besides being called KNI, SSE was also called MMX-2 by some before it was released. In addition to adding more MMX style instructions, the SSE instructions allow for floating-point calculations and now use a separate unit within the processor instead of sharing the standard floating-point unit as MMX did.

SSE2 was introduced in November 2000, along with the Pentium 4 processor, and adds 144 additional SIMD instructions. SSE2 also includes all the previous MMX and SSE instructions.

The Streaming SIMD Extensions consist of new instructions, including SIMD floating-point, additional SIMD integer, and cacheability control instructions. Some of the technologies that benefit from the Streaming SIMD Extensions include advanced imaging, 3D video, streaming audio and video (DVD playback), and speech-recognition applications. The benefits of SSE include the following:

- Higher resolution and higher quality image viewing and manipulation for graphics software
- High-quality audio, MPEG2 video, and simultaneous MPEG2 encoding and decoding for multimedia applications
- Reduced CPU utilization for speech recognition, as well as higher accuracy and faster response times when running speech-recognition software

The SSE and SSE2 instructions are particularly useful with MPEG2 decoding, which is the standard scheme used on DVD video discs. SSE-equipped processors should therefore be more capable of performing MPEG2 decoding in software at full speed without requiring an additional hardware MPEG2 decoder card. SSE-equipped processors are much better and faster than previous processors when it comes to speech recognition, as well.

One of the main benefits of SSE over plain MMX is that it supports single-precision floating-point SIMD operations, which have posed a bottleneck in the 3D graphics processing. Just as with plain MMX, SIMD enables multiple operations to be performed per processor instruction. Specifically, SSE supports up to four floating-point operations per cycle; that is, a single instruction can operate on four pieces of data simultaneously. SSE floating-point instructions can be mixed with MMX instructions with no performance penalties. SSE also supports data *prefetching*, which is a mechanism for reading data into the cache before it is actually called for.

Note that for any of the SSE instructions to be beneficial, they must be encoded in the software you are using, so SSE-aware applications must be used to see the benefits. Most software companies writing graphics- and sound-related software today have updated those applications to be SSE aware and use the features of SSE. For example, high-powered graphics applications such as Adobe Photoshop support SSE instructions for higher performance on processors equipped with SSE. Microsoft includes support for SSE in its DirectX 6.1 and later video and sound drivers, which are included with Windows 98 Second Edition, Windows Me, Windows NT 4.0 (with service pack 5 or later), and Windows 2000.

SSE is an extension to MMX, and SSE2 is an extension to SSE; therefore, processors that support SSE2 also support the SSE instructions, and processors that support SSE also support the original MMX instructions. This means that standard MMX-enabled applications run as they did on MMX-only processors.

3DNow and Enhanced 3DNow

3DNow technology is AMD's alternative to the SSE instructions in the Intel processors. Actually, 3DNow originally came out in the K6 series before Intel released SSE in the Pentium III, and then AMD added Enhanced 3DNow to the Athlon and Duron processors. AMD licensed MMX from Intel, and all its K6 series, Athlon, Duron, and later processors include full MMX instruction support. Not wanting to additionally license the SSE instructions being developed by Intel, AMD first came up with a different set of extensions beyond MMX called 3DNow. Introduced in May 1998 in the K6-2 processor and later enhanced when the Athlon was introduced in June 1999, 3DNow and Enhanced 3DNow are sets of instructions that extend the multimedia capabilities of the AMD chips beyond MMX. This enables greater performance for 3D graphics, multimedia, and other floating-point–intensive PC applications.

3DNow technology is a set of 21 instructions that uses SIMD techniques to operate on arrays of data rather than single elements. Enhanced 3DNow adds 24 more instructions to the original 21 for a total of 45 new instructions. Positioned as an extension to MMX technology, 3DNow is similar to the SSE found in the Pentium III and Celeron processors from Intel. According to AMD, 3DNow provides approximately the same level of improvement to MMX as did SSE, but in fewer instructions with less complexity. Although similar in capability, they are not compatible at the instruction level, so software specifically written to support SSE does not support 3DNow, and vice versa.

Just as with SSE, 3DNow also supports single precision floating-point SIMD operations and enables up to four floating-point operations per cycle. 3DNow floating-point instructions can be mixed with MMX instructions with no performance penalties. 3DNow also supports data prefetching.

Also like SSE, 3DNow is well supported by software, including Windows 9x, Windows NT 4.0, and all newer Microsoft operating systems. Application programming interfaces such as Microsoft's DirectX 6.x API and SGI's Open GL API have been optimized for 3DNow technology as have the drivers for many leading 3D graphic accelerator suppliers, including 3Dfx, ATI, Matrox, and nVidia. Although many games and video drivers support 3DNow, support is lacking from some of the major business graphics applications, such as Adobe Photoshop.

Dynamic Execution

First used in the P6 or sixth-generation processors, *dynamic execution* is an innovative combination of three processing techniques designed to help the processor manipulate data more efficiently. Those techniques are multiple branch prediction, data flow analysis, and speculative execution. Dynamic execution enables the processor to be more efficient by manipulating data in a more logically ordered fashion rather than simply processing a list of instructions, and it is one of the hallmarks of all sixth-generation processors.

The way software is written can dramatically influence a processor's performance. For example, performance is adversely affected if the processor is frequently required to stop what it is doing and jump or branch to a point elsewhere in the program. Delays also occur when the processor cannot process a new instruction until the current instruction is completed. Dynamic execution enables the processor to not only dynamically predict the order of instructions, but execute them out of order internally, if necessary, for an improvement in speed.

Multiple Branch Prediction

Multiple branch prediction predicts the flow of the program through several branches. Using a special algorithm, the processor can anticipate jumps or branches in the instruction flow. It uses this to predict where the next instructions can be found in memory with an accuracy of 90% or greater. This is possible because, while the processor is fetching instructions, it is also looking at instructions further ahead in the program.

Data Flow Analysis

Data flow analysis analyzes and schedules instructions to be executed in an optimal sequence, independent of the original program order. The processor looks at decoded software instructions and determines whether they are available for processing or are instead dependent on other instructions to be executed first. The processor then determines the optimal sequence for processing and executes the instructions in the most efficient manner.

Speculative Execution

Speculative execution increases performance by looking ahead of the program counter and executing instructions that are likely to be needed later. Because the software instructions being processed are based on predicted branches, the results are stored in a pool for later referral. If they are to be executed by the resultant program flow, the already completed instructions are retired and the results are committed to the processor's main registers in the original program execution order. This technique essentially enables the processor to complete instructions in advance and then grab the already completed results when necessary.

Dual Independent Bus Architecture

The Dual Independent Bus (DIB) architecture was first implemented in the sixth-generation processors from Intel and AMD. DIB was created to improve processor bus bandwidth and performance. Having two (dual) independent data I/O buses enables the processor to access data from either of its buses simultaneously and in parallel, rather than in a singular sequential manner (as in a single-bus system). The main (often called front-side) processor bus is the interface between the processor and the motherboard or chipset. The second (back-side) bus in a processor with DIB is used for the L2 cache, enabling it to run at much greater speeds than if it were to share the main processor bus.

Note

The DIB architecture is explained more fully in Chapter 4. For an example of the typical Pentium II/III system architecture, see Figure 4.34.

Two buses make up the DIB architecture: the L2 cache bus and the processor-to-main-memory, or system, bus. The P6 class processors from the Pentium Pro to the Celeron, Pentium II/III/4, and Athlon/Duron processors can use both buses simultaneously, eliminating a bottleneck there. The DIB architecture enables the L2 cache of the 1GHz Pentium III or Athlon, for example, to run 15 times faster than the L2 cache of older Pentium and K6 processors. Because the back-side, or L2 cache, bus is coupled to the speed of the processor core as the frequency of processors increases, so will the speed of the L2 cache increase.

The key to implementing DIB was to move the L2 cache memory off the motherboard and into the processor package. L1 cache always has been a direct part of the processor die, but L2 was larger and had to be external. By moving the L2 cache into the processor, the L2 cache could run at speeds more like the L1 cache, much faster than the motherboard or processor bus. To move the L2 cache into the processor initially, modifications had to be made to the CPU socket or slot. Two slot-based and five socket-based solutions fully support DIB: Slot 1 (Pentium II/III/Celeron), Slot A (Athlon), Socket 8 (Pentium Pro), Socket 370 (Pentium III/Celeron), Socket 423 (Pentium 4), Socket A (Athlon/Duron), and Socket 603 (Xeon).

DIB also enables the system bus to perform multiple simultaneous transactions (instead of singular sequential transactions), accelerating the flow of information within the system and boosting performance. Overall, DIB architecture offers up to three times the bandwidth performance over a single-bus architecture processor.

Processor Manufacturing

Processors are manufactured primarily from silicon, the second most common element on the planet (only the element oxygen is more common). Silicon is the primary ingredient in beach sand; however, in that form it isn't pure enough to be used in chips.

The manner in which silicon is formed into chips is a lengthy process that starts by growing pure silicon crystals via what is called the Czochralski method (named after the inventor of the process). In this method, electric arc furnaces transform the raw materials (primarily quartz rock that is mined) into metallurgical-grade silicon. Then to further weed out impurities, the silicon is converted to a liquid, distilled, and then redeposited in the form of semiconductor-grade rods, which are 99.999999% pure. These rods are then mechanically broken up into chunks and packed into quartz crucibles, which are loaded into electric crystal pulling ovens. There the silicon chunks are melted at more than 2,500° Fahrenheit. To prevent impurities, the ovens usually are mounted on very thick concrete cubes—often on a suspension to prevent any vibration, which would damage the crystal as it forms.

After the silicon is melted, a small seed crystal is inserted into the molten silicon and slowly rotated (see Figure 3.3). As the seed is pulled out of the molten silicon, some of the silicon sticks to the seed and hardens in the same crystal structure as the seed. By carefully controlling the pulling speed (10–40 millimeters per hour) and temperature (approximately 2,500° F), the crystal grows with a narrow neck that then widens into the full desired diameter. Depending on the chips being made, each ingot is approximately 8 or 12 inches in diameter and more than 5 feet long, weighing hundreds of pounds.

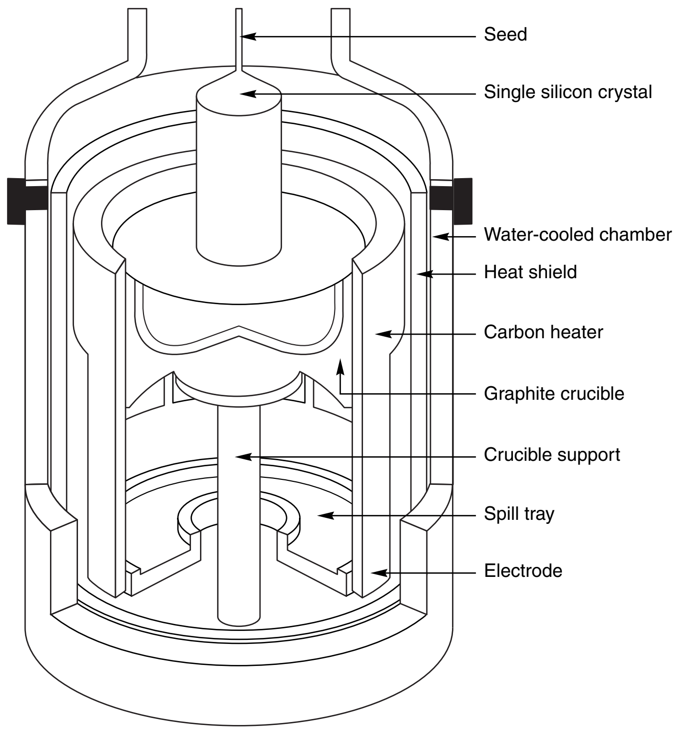

Figure 3.3 Growing a pure silicon ingot in a high-pressure, high-temperature oven.

The ingot is then ground into a perfect 200mm- (8-inch) or 300mm-diameter cylinder, with a flat cut on one side for positioning accuracy and handling. Each ingot is then cut with a high-precision diamond saw into more than a thousand circular wafers, each less than a millimeter thick (see Figure 3.4). Each wafer is then polished to a mirror-smooth surface.

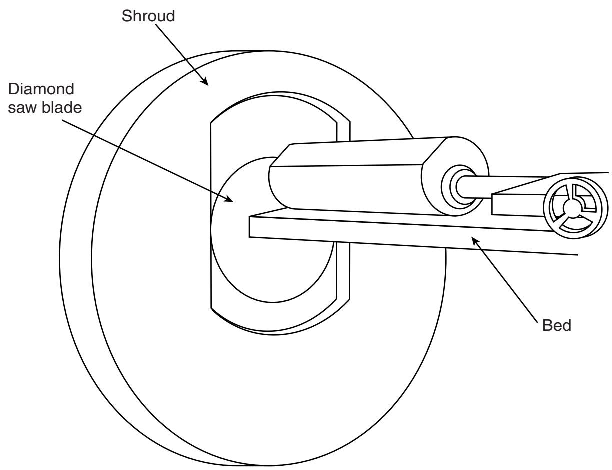

Figure 3.4 Slicing a silicon ingot into wafers with a diamond saw.

Chips are manufactured from the wafers using a process called *photolithography*. Through this photographic process, transistors and circuit and signal pathways are created in semiconductors by depositing different layers of various materials on the chip, one after the other. Where two specific circuits intersect, a transistor or switch can be formed.

The photolithographic process starts when an insulating layer of silicon dioxide is grown on the wafer through a vapor deposition process. Then a coating of photoresist material is applied, and an image of that layer of the chip is projected through a mask onto the now light-sensitive surface.

Doping is the term used to describe chemical impurities added to silicon (which is naturally a nonconductor), creating a material with semiconductor properties. The projector uses a specially created mask, which is essentially a negative of that layer of the chip etched in chrome on a quartz plate. The Pentium III currently uses 20 or more masks to create six layers of metal and semiconductor interconnects.

As the light passes through a mask, the light is focused on the wafer surface, imprinting it with the image of that layer of the chip. Each individual chip image is called a *die*. A device called a *stepper* then moves the wafer over a little bit, and the same mask is used to imprint another chip die immediately next to the previous one. After the entire wafer is imprinted with chips, a caustic solution washes away the areas where the light struck the photoresist, leaving the mask imprints of the individual chip vias (interconnections between layers) and circuit pathways. Then, another layer of semiconductor material is deposited on the wafer with more photoresist on top, and the next mask is used to produce the next layer of circuitry. Using this method, the layers and components of each chip are built one on top of the other until the chips are completed.

The final masks add the *metallization* layers, which are the metal interconnects used to tie all the individual transistors and other components together. Most chips use aluminum interconnects, although during 2002 many will be moving to copper. The first commercial PC processor chip to use copper is the 0.18 micron Athlon made in AMD's Dresden fab. Copper is a better conductor than aluminum and allows smaller interconnects with less resistance, meaning smaller and faster chips can be made. The reason copper hasn't been used up until recently is that there were difficult corrosion problems to overcome during the manufacturing process that were not as much of a problem with aluminum. Now that these problems have been solved, more and more chips will be fabricated with copper interconnects.

Note

The Pentium III and Celeron chips with the "coppermine" (codename for the 0.18 micron die used in those chips) die use aluminum and not copper metal interconnects as many people assume. The chip name had nothing to do with metal; it was instead named after the Coppermine River in the Northwest Territory of Canada. Intel has long had a fondness for using codenames based on rivers (and sometimes, other geological features), especially those in the northwest region of the North American continent. For example, the previous version of the Pentium III (0.25 micron die) was codenamed Katmai, after an Alaskan river. Current Intel code names read like the travel itinerary of a whitewater rafting enthusiast: Deerfield, Foster, Northwood, Tualatin, Gallatin, McKinley, and Madison are all rivers in Oregon, California, Alaska, Montana, and—in the case of Deerfield—Massachusetts and Vermont.

A completed circular wafer has as many chips imprinted on it as can possibly fit. Because each chip usually is square or rectangular, there are some unused portions at the edges of the wafer, but every attempt is made to use every square millimeter of surface.

The standard wafer size used in the industry today is 200mm in diameter, or just under 8 inches. This results in a wafer of about 31,416 square millimeters. The Pentium II 300MHz processor, for example, was made up of 7.5 million transistors using a 0.35 micron (millionth of a meter) process. This process results in a die of exactly 14.2mm on each side, which is 202 square millimeters of area. This means that about 150 total Pentium II 300MHz chips on the .35 micron process could be made from a single 200mm-diameter wafer.

The trend in the industry is to go to both larger wafers and a smaller chip die process. *Process* refers to the size of the individual circuits and transistors on the chip. For example, the Pentium II 333MHz through 450MHz processors were made on a newer and smaller .25 micron process, which reduced the total chip die size to only 10.2mm on each side, or a total chip area of 104 square millimeters. On the same 200mm (8-inch) wafer as before, Intel can make about 300 Pentium II chips using this process, or double the amount of the larger .35 micron process 300MHz version.

The Pentium III in the 600MHz and faster speeds is built on a .18 micron process and has a die size of only 104 square millimeters, which is about 10.2mm on each side. This is the same size as the older Pentium II, even though the newer PIII has 28.1 million transistors (including the on-die L2 cache) compared to only 7.5 million for the Pentium II. The Tualatin die version of the Pentium III uses a 0.13 micron process, as does the Northwood die version of the Pentium 4.

The industry is going through several transitions in chip manufacturing. The processes are moving from .18 micron to .13 micron, and wafers are moving from 200mm (8-inch) wafers to 300mm (12-inch) wafers. The larger 300mm wafers alone will enable more than double the number of chips to be made, compared to the 200mm mostly used today. The smaller 0.13-micron process will enable more transistors to be incorporated into the die while maintaining a reasonable die size allowing for sufficient yield. This means the trend for incorporating L2 cache within the die will continue, and transistor counts will rise up to 200 million per chip or more in the future. The current king of transistors is the Intel Pentium III Xeon introduced in May 2000 with 2MB of on-die cache and a whopping 140 million transistors in a single die.

The trend in wafers is to move from the current 200mm (8-inch) diameter to a bigger, 300mm (12-inch) diameter wafer. This will increase surface area dramatically over the smaller 200mm design and boost chip production to about 675 chips per wafer. Intel and other manufacturers expect to have 300mm wafer production in place during 2002. After that happens, chip prices should continue to drop dramatically as supply increases.

Note that not all the chips on each wafer will be good, especially as a new production line starts. As the manufacturing process for a given chip or production line is perfected, more and more of the chips will be good. The ratio of good to bad chips on a wafer is called the *yield*. Yields well under 50% are common when a new chip starts production; however, by the end of a given chip's life, the yields are normally in the 90% range. Most chip manufacturers guard their yield figures and are very secretive about them because knowledge of yield problems can give their competitors an edge. A low yield causes problems both in the cost per chip and in delivery delays to their customers. If a company has specific knowledge of competitors' improving yields, it can set prices or schedule production to get higher market share at a critical point. For example, AMD was plagued by low-yield problems during 1997 and 1998, which cost it significant market share. It has since solved the problems, and lately it seems Intel has had the harder time meeting production demands.

After a wafer is complete, a special fixture tests each of the chips on the wafer and marks the bad ones to be separated out later. The chips are then cut from the wafer using either a high-powered laser or diamond saw.

After being cut from the wafers, the individual dies are then retested, packaged, and retested again. The packaging process is also referred to as *bonding* because the die is placed into a chip housing in which a special machine bonds fine gold wires between the die and the pins on the chip. The package is the container for the chip die, and it essentially seals it from the environment.

After the chips are bonded and packaged, final testing is done to determine both proper function and rated speed. Different chips in the same batch often run at different speeds. Special test fixtures run each chip at different pressures, temperatures, and speeds, looking for the point at which the chip stops working. At this point, the maximum successful speed is noted and the final chips are sorted into bins with those that tested at a similar speed. For example, the Pentium III 750, 866, and 1000 are all exactly the same chip made using the same die. They were sorted at the end of the manufacturing cycle by speed.

One interesting thing about this is that as a manufacturer gains more experience and perfects a particular chip assembly line, the yield of the higher-speed versions goes way up. This means that out of a wafer of 150 total chips, perhaps more than 100 of them check out at 1000MHz, whereas only a few won't run at that speed. The paradox is that Intel often sells a lot more of the lower-priced 933 and 866MHz chips, so it will just dip into the bin of 1000MHz processors and label them as 933 or 866 chips and sell them that way. People began discovering that many of the lower-rated chips would actually run at speeds much higher than they were rated, and the business of overclocking was born.

An interesting problem then arose: Unscrupulous vendors began re-marking slower chips and reselling them as if they were faster. Often the price between the same chip at different speed grades can be substantial—in the hundreds of dollars—so by changing a few numbers on the chip, the potential profits can be huge. Because most of the Intel and AMD processors are produced with a generous safety margin—that is, they typically run well past their rated speeds—the re-marked chips would seem to work fine in most cases. Of course, in many cases they wouldn't work fine, and the system would end up crashing or locking up periodically.

At first the re-marked chips were just a case of rubbing off the original numbers and restamping with new official-looking numbers. These were easy to detect, though. Re-markers then resorted to manufacturing completely new processor housings, especially for the plastic-encased Slot 1 and Slot A processors from Intel and AMD. Although it might seem to be a huge bother to make a custom plastic case and swap it with the existing case, because the profits can be huge, criminals find it very lucrative. This type of re-marking is a form of organized crime and isn't just some kid in his basement with sandpaper and a rubber stamp.

Intel and AMD have seen fit to put a stop to some of the re-marking by building overclock protection in the form of a multiplier lock into most of its newer chips. This is usually done in the bonding or cartridge manufacturing process, where the chips are intentionally altered so they won't run at any speeds higher than they are rated. Usually this involves changing the bus frequency (BF) pins on the chip, which control the internal multipliers the chip uses. Even so, enterprising individuals have found ways to run their motherboards at bus speeds higher than normal, so even though the chip won't allow a higher multiplier, you can still run it at a speed higher than it was designed for.

Be Wary of PII and PIII Overclocking Fraud

Also note that unscrupulous individuals have devised a small logic circuit that bypasses the multiplier lock, enabling the chip to run at higher multipliers. This small circuit can be hidden in the PII or PIII cartridge, and then the chip can be re-marked or relabeled to falsely indicate it is a higher-speed version. This type of chip remarketing fraud is far more common in the industry than people want to believe. In fact, if you purchase your system or processor from a local computer flea market show, you have an excellent chance of getting a re-marked chip. I recommend purchasing processors only from more reputable direct distributors or dealers. You can contact Intel, AMD, or Cyrix for a list of them.

I recently installed a 200MHz Pentium processor in a system that is supposed to run at a 3x multiplier based off a 66MHz motherboard speed. I tried changing the multiplier to 3.5x, but the chip refused to go any faster; in fact, it ran at the same or lower speed than before. This is a sure sign of overclock protection inside, which is to say that the chip won't support any higher level of multiplier than it was designed for. Today, all Intel Pentium II and III processors are multiplier locked, which means the multiplier can no longer be controlled by the motherboard. So, overclocking can be accomplished only by running the motherboard at a higher bus speed than the processor was designed for. My motherboard at the time included a jumper setting for an unauthorized speed of 75MHz, which when multiplied by 3x resulted in an actual processor speed of 225MHz. This worked like a charm, and the system is now running fast and clean. Many new motherboards have BIOS or jumper settings that can be used to tweak the motherboard bus speeds a few MHz higher than normal, which is then internally multiplied by the processor to even higher speeds. Note that I am not necessarily recommending overclocking for everybody; in fact, I normally don't recommend it at all for any important systems. If you have a system you want to fool around with, it is interesting to try. Like my cars, I always seem to want to hotrod my computers.

The real problem with the overclock protection as implemented by Intel and AMD is that the professional counterfeiter can still override it by inserting some custom circuitry underneath the plastic case enclosing the processor. This again is particularly a problem with the slot-based processors because they use a case cover that can hide this circuitry. Socketed processors are much more immune to these re-marking attempts. To protect yourself from purchasing a fraudulent chip, verify the specification numbers and serial numbers with Intel and AMD before you purchase. Also beware where you buy your hardware. Purchasing over online auction sites can be extremely dangerous because defrauding the purchaser is so easy. Also, the traveling computer show/flea market arenas can be a hotbed of this type of activity.

Fraudulent computer components are not limited to processors. I have seen fake memory (SIMMs/DIMMs), fake mice, fake video cards, fake cache memory, counterfeit operating systems and applications, and even fake motherboards. The hardware that is faked usually works but is of inferior quality to the type it is purporting to be. For example, one of the most highly counterfeited pieces of hardware is the Microsoft mouse. They sell for $35 wholesale and yet I can purchase cheap mice from overseas manufacturers for as little as $2.32 each. It didn't take somebody long to realize that if they made the $2 mouse look like a $35 Microsoft mouse, they could sell it for $20 and people would think they were getting a genuine article for a bargain, while the thieves run off with a substantial profit.

PGA Chip Packaging

PGA packaging has been the most common chip package used until recently. It was used starting with the 286 processor in the 1980s and is still used today for Pentium and Pentium Pro processors. PGA takes its name from the fact that the chip has a grid-like array of pins on the bottom of the package. PGA chips are inserted into sockets, which are often of a ZIF (zero insertion force) design. A ZIF socket has a lever to allow for easy installation and removal of the chip.

Most Pentium processors use a variation on the regular PGA called staggered pin grid array (SPGA), in which the pins are staggered on the underside of the chip rather than in standard rows and columns. This was done to move the pins closer together and decrease the overall size of the chip when a large number of pins is required. Figure 3.5 shows a Pentium Pro that uses the dual-pattern SPGA (on the right) next to an older Pentium 66 that uses the regular PGA. Note that the right half of the Pentium Pro shown here has additional pins staggered among the other rows and columns.

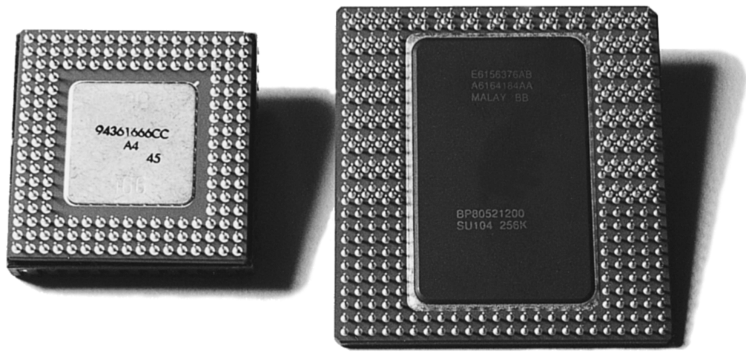

Figure 3.5 PGA on Pentium 66 (left) and dual-pattern SPGA on Pentium Pro (right).

Single Edge Contact and Single Edge Processor Packaging

Abandoning the chip-in-a-socket approach used by virtually all processors until this point, the Pentium II/III chips are characterized by their single edge contact (SEC) cartridge design. The processor, along with several L2 cache chips, is mounted on a small circuit board (much like an oversized memory SIMM), which is then sealed in a metal and plastic cartridge. The cartridge is then plugged into the motherboard through an edge connector called Slot 1, which looks very similar to an adapter card slot.

By placing the processor and L2 cache as separate chips inside a cartridge, Intel now has a CPU module that is easier and less expensive to make than the Pentium Pro that preceded it. The SEC cartridge is an innovative—if a bit unwieldy—package design that incorporates the back-side bus and L2 cache internally. Using the SEC design, the core and L2 cache are fully enclosed in a plastic and metal cartridge. These subcomponents are surface mounted directly to a substrate (or base) inside the cartridge to enable high-frequency operation. The SEC cartridge technology enables the use of widely available, high-performance industry standard burst static RAMs (BSRAMs) for the dedicated L2 cache. This greatly reduces the cost compared to the proprietary cache chips used inside the CPU package in the Pentium Pro.

A less expensive version of the SEC is called the single edge processor (SEP) package. The SEP package is basically the same circuit board containing processor and (optional) cache as the Pentium II, but without the fancy plastic cover. The SEP package plugs directly into the same Slot 1 connector used by the standard Pentium II. Four holes on the board enable the heatsink to be installed.

Slot 1 is the connection to the motherboard and has 242 pins. The Slot 1 dimensions are shown in Figure 3.6. The SEC cartridge or SEP processor is plugged into Slot 1 and secured with a processor-retention mechanism, which is a bracket that holds it in place. There also might be a retention mechanism or support for the processor heatsink. Figure 3.7 shows the parts of the cover that make up the SEC package. Note the large thermal plate used to aid in dissipating the heat from this processor. The SEP package is shown in Figure 3.8.

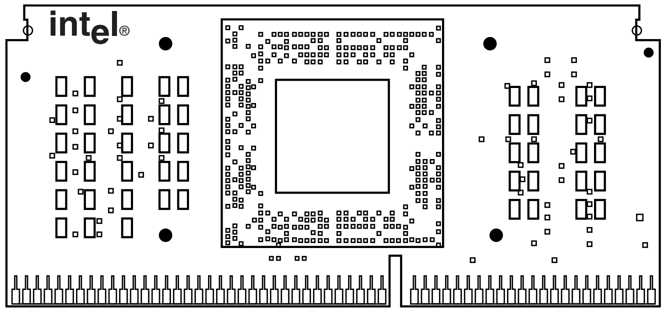

Figure 3.6 Pentium II Processor Slot 1 dimensions (metric/English).

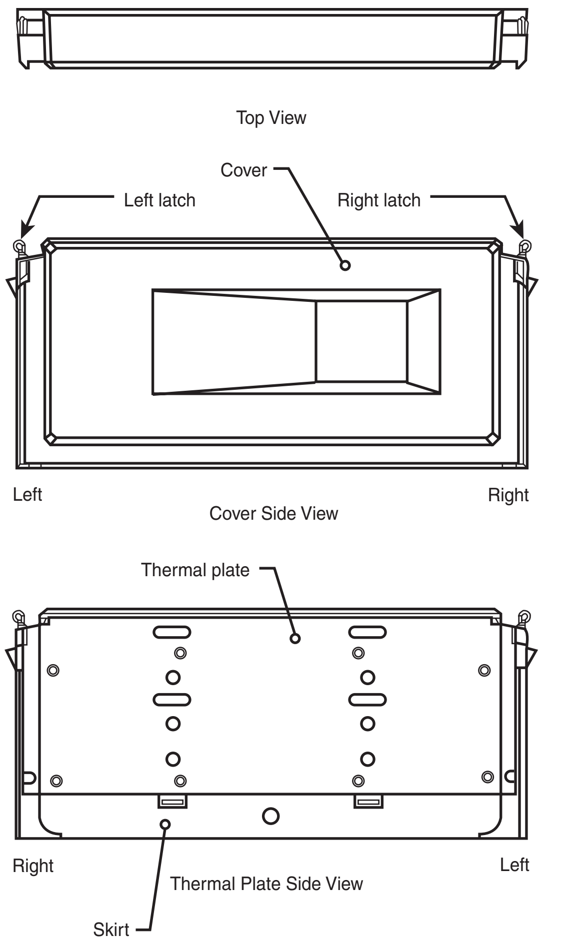

Figure 3.7 Pentium II Processor SEC package parts.

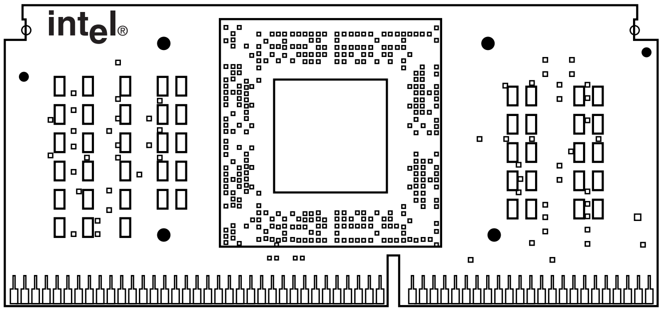

Figure 3.8 Celeron Processor SEP package front-side view.

With the Pentium III, Intel introduced a variation on the SEC packaging called SECC2 (single edge contact cartridge version 2). This new package covers only one side of the processor board and enables the heatsink to directly attach to the chip on the other side. This direct thermal interface allows for better cooling, and the overall lighter package is cheaper to manufacture. Note that a new Universal Retention System, consisting of a plastic upright stand, is required to hold the SECC2 package chip in place on the board. The Universal Retention System also works with the older SEC package as used on most Pentium II processors, as well as the SEP package used on the slot-based Celeron processors. This makes it the ideal retention mechanism for all Slot 1-based processors. Figure 3.9 shows the SECC2 package.

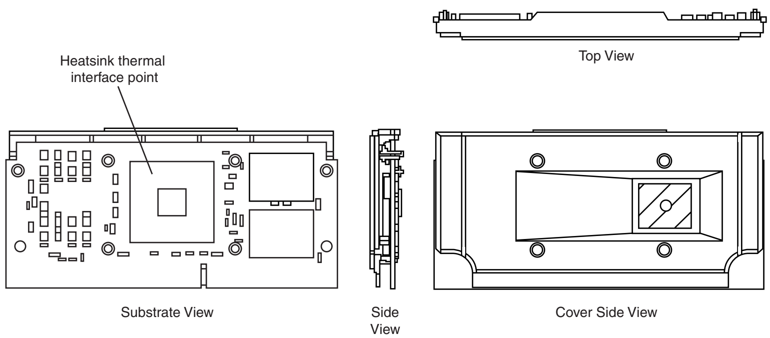

Figure 3.9 SECC2 packaging used in newer Pentium II and III processors.

The main reason for going to the SEC and SEP packages in the first place was to be able to move the L2 cache memory off the motherboard and onto the processor in an economical and scalable way. This has since been superceded in most processors by on-die cache, which eliminates the need for a cartridge.

Processor Sockets and Slots

Intel and AMD have created a set of socket and slot designs for their processors. Each socket or slot is designed to support a different range of original and upgrade processors. Table 3.12 shows the specifications of these sockets.

Table 3.12 CPU Socket and Slot Types and Specifications

Socket Number	Pins	Pin Layout	Voltage	Supported Processors
Socket 1	169	17x17 PGA	5v	486 SX/SX2, DX/DX2[1], DX4 OverDrive
Socket 2	238	19x19 PGA	5v	486 SX/SX2, DX/DX2[1], DX4 OverDrive, 486 Pentium OverDrive
Socket 3	237	19x19 PGA	5v/3.3v	486 SX/SX2, DX/DX2, DX4, 486 Pentium OverDrive, AMD 5x86
Socket 4	273	21x21 PGA	5v	Pentium 60/66, OverDrive
Socket 5	320	37x37 SPGA	3.3/3.5v	Pentium 75-133, OverDrive
Socket 6[2]	235	19x19 PGA	3.3v	486 DX4, 486 Pentium OverDrive
Socket 7	321	37x37 SPGA	VRM	Pentium 75–233+, MMX, OverDrive, AMD K5/K6, Cyrix M1/II
Socket 8	387	dual-pattern SPGA	Auto VRM	Pentium Pro, OverDrive
Socket 370	370	37x37 SPGA	Auto VRM	Celeron/Pentium III PPGA/FC-PGA
Socket PAC418	418	38x22 split SPGA	Auto VRM	Itanium
Socket 423	423	39x39 SPGA	Auto VRM	Pentium 4
Socket A (462)	462	37x37 SPGA	Auto VRM	AMD Athlon/Duron PGA
Socket 603	603	31x25 SPGA	Auto VRM	Xeon (P4)
Slot A	242	Slot	Auto VRM	AMD Athlon SECC
Slot 1 (SC242)	242	Slot	Auto VRM	Pentium II/III, Celeron SECC
Slot 2 (SC330)	330	Slot	Auto VRM	Pentium II/III Xeon SECC

1. Nonoverdrive DX4 or AMD 5x86 also can be supported with the addition of an aftermarket 3.3v voltage-regulator adapter.

2. Socket 6 was a paper standard only and was never actually implemented in any systems.

PGA = Pin grid array

PPGA = Plastic pin grid array

FC-PGA = Flip chip pin grid array

SPGA = Staggered pin grid array

SECC = Single edge contact cartridge

PAC = Pin array cartridge

VRM = Voltage regulator module

Sockets 1, 2, 3, and 6 are 486 processor sockets and are shown together in Figure 3.10 so you can see the overall size comparisons and pin arrangements between these sockets. Sockets 4, 5, 7, and 8 are Pentium and Pentium Pro processor sockets and are shown together in Figure 3.11 so you can see the overall size comparisons and pin arrangements between these sockets. More detailed drawings of each socket are included throughout the remainder of this section with the thorough descriptions of the sockets.

Socket 1

The original OverDrive socket, now officially called Socket 1, is a 169-pin PGA socket. Motherboards that have this socket can support any of the 486SX, DX, and DX2 processors and the DX2/OverDrive versions. This type of socket is found on most 486 systems that originally were designed for OverDrive upgrades. Figure 3.12 shows the pinout of Socket 1.

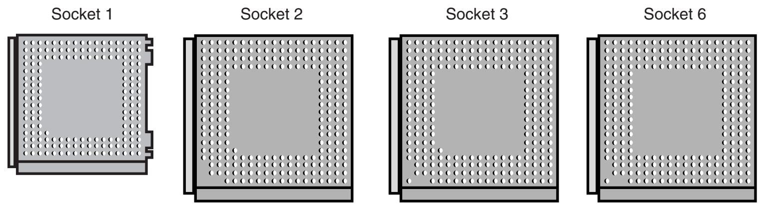

Figure 3.10 486 processor sockets.

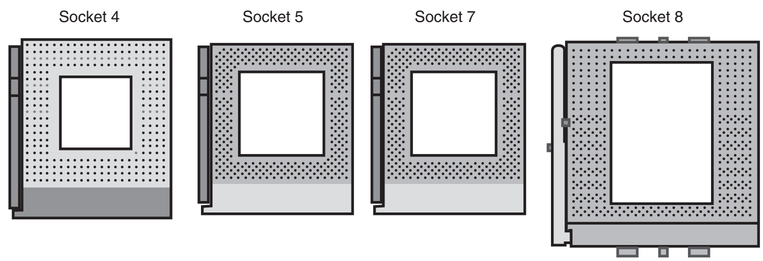

Figure 3.11 Pentium and Pentium Pro processor sockets.

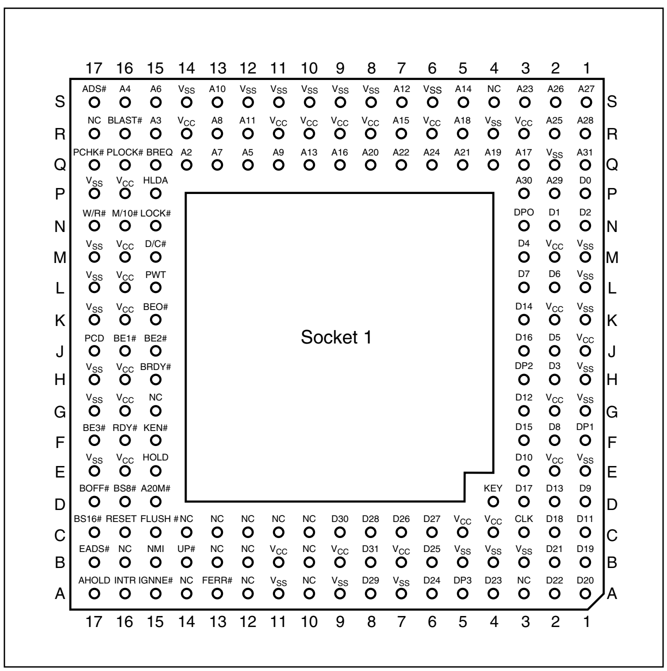

Figure 3.12 Intel Socket 1 pinout.

The original DX processor draws a maximum 0.9 amps of 5v power in 33MHz form (4.5 watts) and a maximum 1 amp in 50MHz form (5 watts). The DX2 processor, or OverDrive processor, draws a maximum 1.2 amps at 66MHz (6 watts). This minor increase in power requires only a passive heatsink consisting of aluminum fins that are glued to the processor with thermal transfer epoxy. Passive heatsinks don't have any mechanical components like fans. Heatsinks with fans or other devices that use power are called *active* heatsinks. OverDrive processors rated at 40MHz or less do not have heatsinks.

Socket 2

When the DX2 processor was released, Intel was already working on the new Pentium processor. The company wanted to offer a 32-bit, scaled-down version of the Pentium as an upgrade for systems that originally came with a DX2 processor. Rather than just increasing the clock rate, Intel created an all-new chip with enhanced capabilities derived from the Pentium.

The chip, called the Pentium OverDrive processor, plugs into a processor socket with the Socket 2 or Socket 3 design. These sockets hold any 486 SX, DX, or DX2 processor, as well as the Pentium OverDrive. Because this chip is essentially a 32-bit version of the (normally 64-bit) Pentium chip, many have taken to calling it a Pentium-SX. It was available in 25/63MHz and 33/83MHz versions. The first number indicates the base motherboard speed; the second number indicates the actual operating speed of the Pentium OverDrive chip. As you can see, it is a clock-multiplied chip that runs at 2.5 times the motherboard speed. Figure 3.13 shows the pinout configuration of the official Socket 2 design.

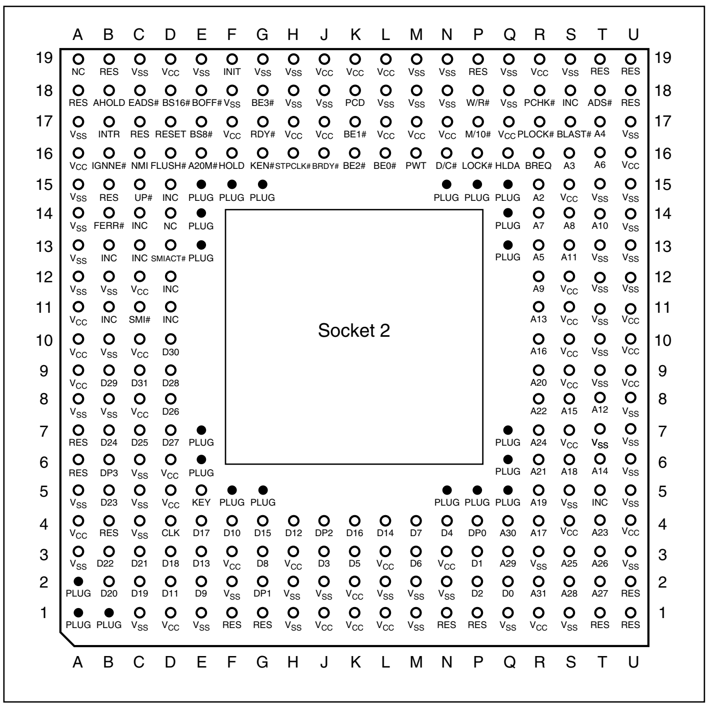

Figure 3.13 238-pin Intel Socket 2 configuration.

Notice that although the new chip for Socket 2 is called Pentium OverDrive, it is not a full-scale (64-bit) Pentium. Intel released the design of Socket 2 a little prematurely and found that the chip ran too hot for many systems. The company solved this problem by adding a special active heatsink to the Pentium OverDrive processor. This active heatsink is a combination of a standard heatsink and a built-in electric fan. Unlike the aftermarket glue-on or clip-on fans for processors that you might have seen, this one actually draws 5v power directly from the socket to drive the fan. No external connection to disk drive cables or the power supply is required. The fan/heatsink assembly clips and plugs directly into the processor and provides for easy replacement if the fan fails.

Another requirement of the active heatsink is additional clearance—no obstructions for an area about 1.4 inches off the base of the existing socket to allow for heatsink clearance. The Pentium OverDrive upgrade is difficult or impossible in systems that were not designed with this feature.

Another problem with this particular upgrade is power consumption. The 5v Pentium OverDrive processor draws up to 2.5 amps at 5v (including the fan) or 12.5 watts, which is more than double the 1.2 amps (6 watts) drawn by the DX2 66 processor.

Note

See Intel's Web site (`http://www.intel.com`) for a comprehensive list of certified OverDrive-compatible systems.

Socket 3

Because of problems with the original Socket 2 specification and the enormous heat the 5v version of the Pentium OverDrive processor generates, Intel came up with an improved design. The new processor is the same as the previous Pentium OverDrive processor, except that it runs on 3.3v and draws a maximum 3.0 amps of 3.3v (9.9 watts) and 0.2 amp of 5v (1 watt) to run the fan—a total of 10.9 watts. This configuration provides a slight margin over the 5v version of this processor. The fan is easy to remove from the OverDrive processor for replacement, should it ever fail.

Intel had to create a new socket to support both the DX4 processor, which runs on 3.3v, and the 3.3v Pentium OverDrive processor. In addition to the new 3.3v chips, this new socket supports the older 5v SX, DX, DX2, and even the 5v Pentium OverDrive chip. The design, called Socket 3, is the most flexible upgradable 486 design. Figure 3.14 shows the pinout specification of Socket 3.

Notice that Socket 3 has one additional pin and several others plugged in compared with Socket 2. Socket 3 provides for better keying, which prevents an end user from accidentally installing the processor in an improper orientation. However, one serious problem exists: This socket cannot automatically determine the type of voltage that is provided to it. You will likely find a jumper on the motherboard near the socket to enable selecting 5v or 3.3v operation.

Caution

Because this jumper must be manually set, however, a user could install a 3.3v processor in this socket when it is configured for 5v operation. This installation instantly destroys the chip when the system is powered on. So, it is up to the end user to ensure that this socket is properly configured for voltage, depending on which type of processor is installed. If the jumper is set in 3.3v configuration and a 5v processor is installed, no harm will occur, but the system will not operate properly unless the jumper is reset for 5v.

Socket 4

Socket 4 is a 273-pin socket designed for the original Pentium processors. The original Pentium 60MHz and 66MHz version processors had 273 pins and plugged into Socket 4—a 5v-only socket because all the original Pentium processors run on 5v. This socket accepts the original Pentium 60MHz or 66MHz processor and the OverDrive processor. Figure 3.15 shows the pinout specification of Socket 4.

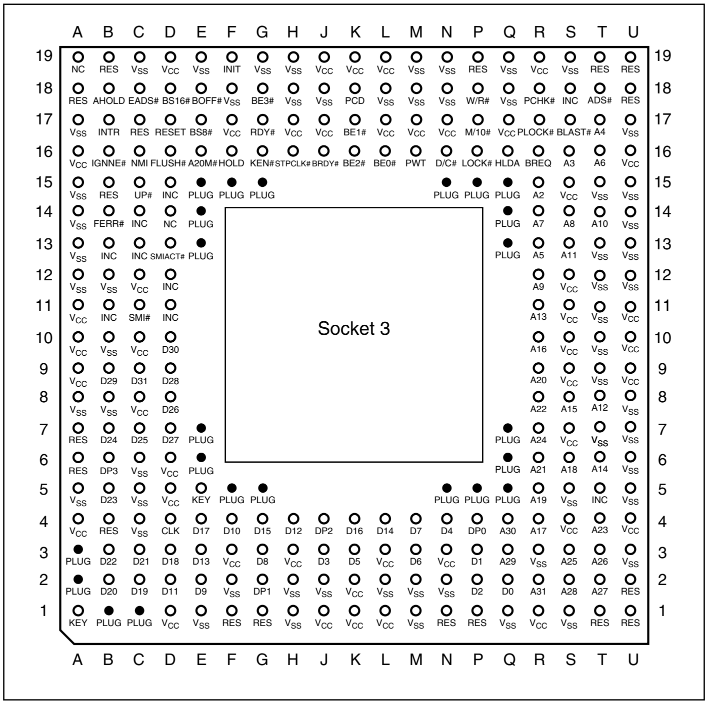

Figure 3.14 237-pin Intel Socket 3 configuration.

Somewhat amazingly, the original Pentium 66MHz processor consumes up to 3.2 amps of 5v power (16 watts), not including power for a standard active heatsink (fan). The 66MHz OverDrive processor that replaced it consumes a maximum 2.7 amps (13.5 watts), including about 1 watt to drive the fan. Even the original 60MHz Pentium processor consumes up to 2.91 amps at 5v (14.55 watts). It might seem strange that the replacement processor, which is twice as fast, consumes less power than the original, but this has to do with the manufacturing processes used for the original and OverDrive processors.

Although both processors run on 5v, the original Pentium processor was created with a circuit size of 0.8 micron, making that processor much more power-hungry than the 0.6 micron circuits used in the OverDrive and the other Pentium processors. Shrinking the circuit size is one of the best ways to decrease power consumption. Although the OverDrive processor for Pentium-based systems draws less power than the original processor, additional clearance might have to be allowed for the active heatsink assembly that is mounted on top. As in other OverDrive processors with built-in fans, the power to run the fan is drawn directly from the chip socket, so no separate power-supply connection is required. Also, the fan is easy to replace should it ever fail.

Socket 5

When Intel redesigned the Pentium processor to run at 75MHz, 90MHz, and 100MHz, the company went to a 0.6-micron manufacturing process and 3.3v operation. This change resulted in lower power consumption: only 3.25 amps at 3.3v (10.725 watts). Therefore, the 100MHz Pentium processor used far less power than even the original 60MHz version. This resulted in lower power consumption and enabled the extremely high clock rates without overheating.

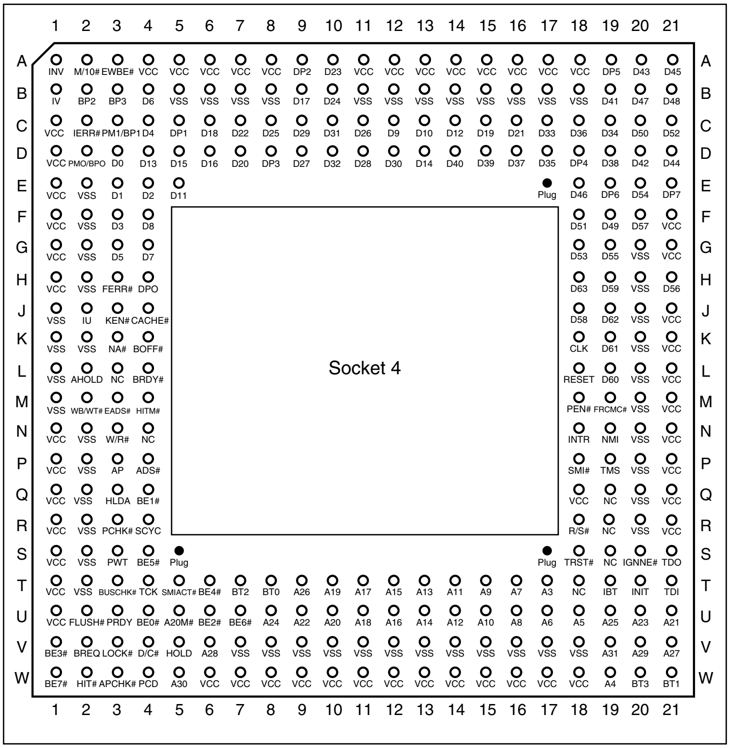

Figure 3.15 273-pin Intel Socket 4 configuration.

The Pentium 75 and higher processors actually have 296 pins, although they plug into the official Intel Socket 5 design, which calls for a total of 320 pins. The additional pins are used by the Pentium OverDrive for Pentium processors. This socket has the 320 pins configured in a staggered PGA, in which the individual pins are staggered for tighter clearance.

Several OverDrive processors for existing Pentiums were available. These usually were later design chips with integral voltage regulators to enable operating on the higher voltages the older chips originally required. Intel no longer sells these; however, companies such as Evergreen and Kingston do still sell upgrade chips for older systems. Figure 3.16 shows the standard pinout for Socket 5.

The Pentium OverDrive for Pentium processors has an active heatsink (fan) assembly that draws power directly from the chip socket. The chip requires a maximum 4.33 amps of 3.3v to run the chip (14.289 watts) and 0.2 amp of 5v power to run the fan (one watt), which results in a total power consumption of 15.289 watts. This is less power than the original 66MHz Pentium processor requires, yet it runs a chip that is as much as four times faster!

Socket 6

The last 486 socket was designed for the 486 DX4 and the 486 Pentium OverDrive processor. Socket 6 was intended as a slightly redesigned version of Socket 3 and had an additional 2 pins plugged for proper chip keying. Socket 6 has 235 pins and accepts only 3.3v 486 or OverDrive processors. Although Intel went to the trouble of designing this socket, it never was built or implemented in any systems. Motherboard manufacturers instead stuck with Socket 3.

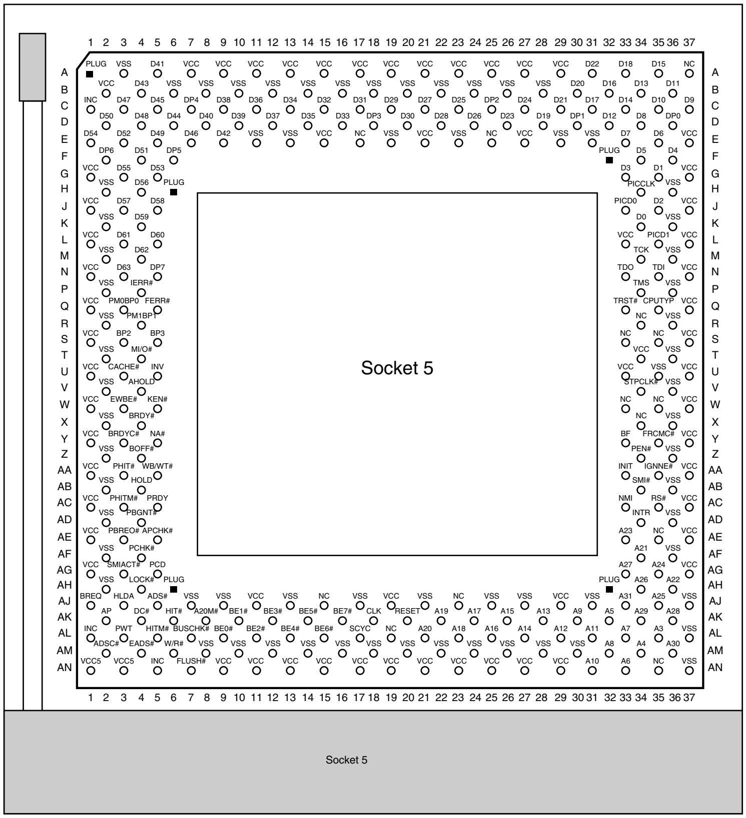

Figure 3.16 320-pin Intel Socket 5 configuration.

Socket 7 (and Super7)

Socket 7 is essentially the same as Socket 5 with one additional key pin in the opposite inside corner of the existing key pin. Socket 7, therefore, has 321 pins total in a 21×21 SPGA arrangement. The real difference with Socket 7 is not the socket but with the companion voltage regulator module (VRM) circuitry on the motherboard that must accompany it.

The VRM is either a small circuit board or a group of circuitry embedded in the motherboard that supplies the proper voltage level and regulation of power to the processor.

The main reason for the VRM is that Intel and AMD wanted to drop the voltages the processors would use from the 3.3V or 5V supplied to the motherboard by the power supply. Rather than require custom power supplies for different processors, the VRM converts the 3.3V or 5V to the proper voltage for the particular CPU you are using. Intel released different versions of the Pentium and Pentium-MMX processors that ran on 3.3v (called VR), 3.465v (called VRE), or 2.8v. Equivalent processors from AMD, Cyrix, and others used different variations of 3.3V, 3.2V, 2.9V, 2.4V, 2.3V, 2.2V, 2.1V, 2.0V, 1.9V, or 1.8V. Because of the variety of voltages that might be required to support different processors, most motherboard manufacturers started including VRM sockets or building adaptable VRMs into their Pentium motherboards.

Figure 3.17 shows the Socket 7 pinout.

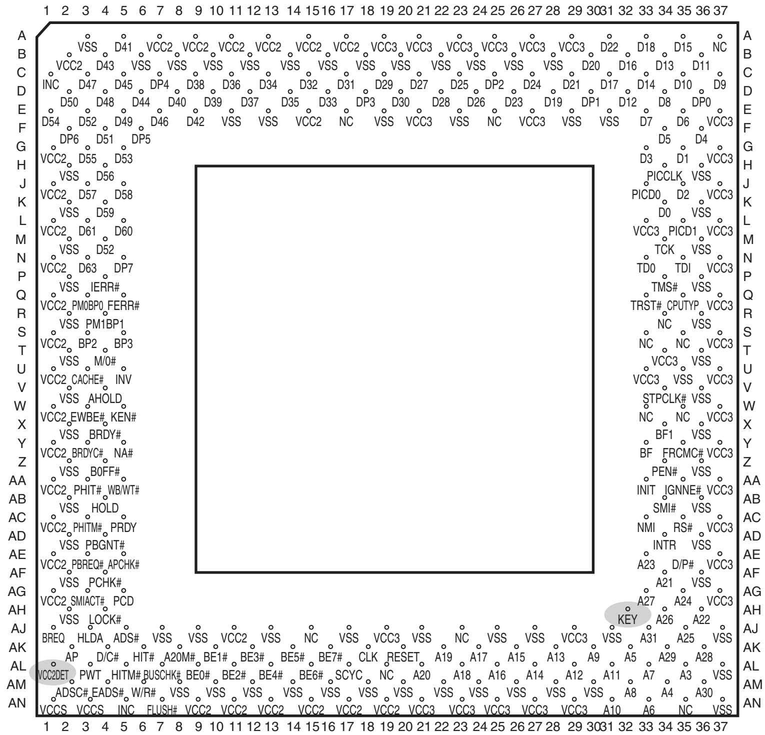

Figure 3.17 Socket 7 (Pentium) pinout (top view).

AMD, along with Cyrix and several chipset manufacturers, pioneered an improvement or extension to the Intel Socket 7 design called Super Socket 7 (or Super7), taking it from 66MHz to 95MHz and 100MHz. This enables faster Socket 7–type systems to be made, which are nearly as fast as the newer Slot 1– and Socket 370–type systems using Intel processors. Super7 systems also have support for the AGP video bus, as well as Ultra DMA hard disk controllers and advanced power management.

New chipsets are required for Super7 boards. Major third-party chipset suppliers, including Acer Laboratories Inc. (ALi), VIA Technologies, and Silicon Integrated Systmes (SiS), all released chipsets for Super7 boards. Most of the major motherboard manufacturers made Super7 boards in both Baby-AT and ATX form factors.

Socket 8

Socket 8 is a special SPGA (socket featuring a whopping 387 pins! This was specifically designed for the Pentium Pro processor with the integrated L2 cache. The additional pins are to enable the chipset to control the L2 cache integrated in the same package as the processor. Figure 3.18 shows the Socket 8 pinout.

Socket 370 (PGA-370)

In January 1999, Intel introduced a new socket for P6 class processors. The new socket is called Socket 370 or PGA-370 because it has 370 pins and originally was designed for lower-cost PGA versions of the Celeron and Pentium III processors. Socket 370 is designed to directly compete in the lower-end system market along with the Super7 platform supported by AMD and Cyrix. Socket 370 brings the low cost of a socketed design, with less expensive processors, mounting systems, heatsinks, and so on to the high-performance P6 line of processors.

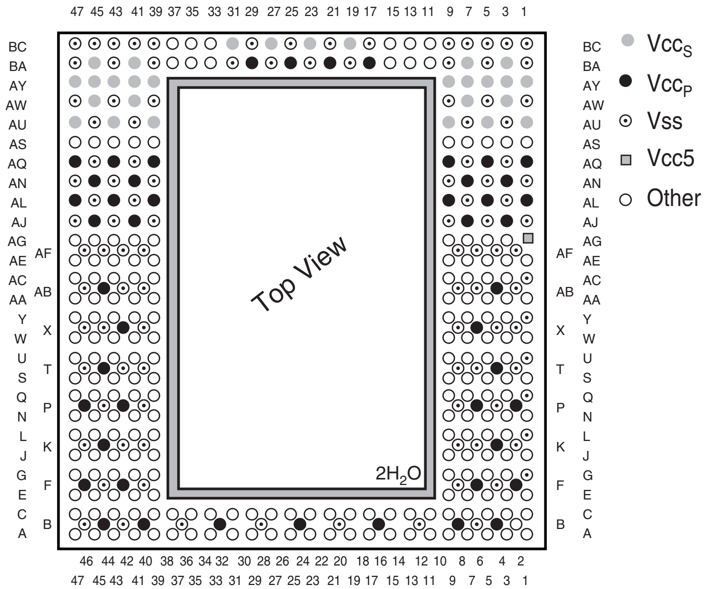

Figure 3.18 Socket 8 (Pentium Pro) pinout showing power pin locations.

Initially all the Celeron and Pentium III processors were made in SECC or SEPP format. These are essentially circuit boards containing the processor and separate L2 cache chips on a small board that plugs into the motherboard via Slot 1. This type of design was necessary when the L2 cache chips were made a part of the processor but were not directly integrated into the processor die. Intel did make a multidie chip package for the Pentium Pro, but this proved to be a very expensive way to package the chip, and a board with separate chips was cheaper, which is why the Pentium II looks different from the Pentium Pro.

Starting with the Celeron 300A processor introduced in August 1998, Intel began combining the L2 cache directly on the processor die; it was no longer in separate chips. With the cache fully integrated into the die, there was no longer a need for a board-mounted processor. Because it costs more to make a Slot 1 board or cartridge-type processor instead of a socketed type, Intel moved back to the socket design to reduce the manufacturing cost—especially with the Celeron, which competes on the low end with Socket 7 chips from AMD and Cyrix.

The Socket 370 (PGA-370) pinout is shown in Figure 3.19.

The Celeron is gradually being shifted over to PGA-370, although for a time both were available. All Celeron processors at 333MHz and lower were available only in the Slot 1 version. Celeron processors from 366MHz to 433MHz were available in both Slot 1 and Socket 370 versions; all Celeron processors from 466MHz and up are available only in the Socket 370 version.

Flip Chip Pin Grid Array

Starting in October 1999, Intel also introduced Pentium III processors with integrated cache that plug into Socket 370. These use a packaging called flip chip pin grid array (FC-PGA), which is a type of packaging in which the raw die is mounted on the substrate upside down. The slot version is more expensive and no longer necessary because of the on-die L2 cache.

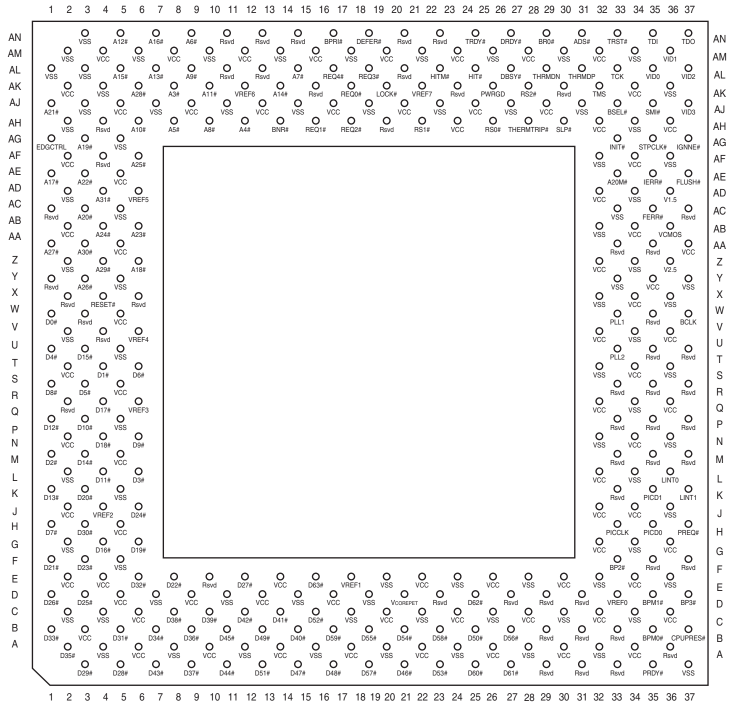

Figure 3.19 Socket 370 (PGA-370) Pentium III/Celeron pinout (top view).

Note that because of some voltage changes and one pin change, many original Socket 370 motherboards do not accept the later FC-PGA versions of the Pentium III and Celeron. Pentium III processors in the FC-PGA form have two RESET pins and require VRM 8.4 specifications. Prior motherboards designed only for the Celeron are referred to as *legacy motherboards*, and the newer motherboards supporting the second RESET pin and VRM 8.4 specification are referred to as *flexible motherboards*. Contact your motherboard or system manufacturer for information to see whether your socket is the flexible version. Some motherboards, such as the Intel CA810, do support the VRM 8.4 specifications and supply proper voltage, but without Vtt support the Pentium III processor in the FC-PGA package will be held in RESET#.

Installing a Pentium III processor in the FC-PGA package into an older motherboard is unlikely to damage the motherboard. However, the processor itself could be damaged. Pentium III processors in the 0.18 micron process operate on either 1.60 or 1.65 volts, whereas the Intel Celeron processors operate at 2.00 volts. The motherboard could possibly be damaged if the motherboard BIOS fails to recognize the voltage identification of the processor. Contact your PC or motherboard manufacturer before installation to ensure compatibility.

A motherboard with a Slot 1 can be designed to accept almost any Celeron, Pentium II, or Pentium III processor. To use the socketed Celerons and Pentium III processors, a low-cost slot-to-socket adapter sometimes called a *slot-ket* has been made available by several manufacturers. This is essentially a Slot 1 board containing only a Socket 370, which enables you to use a PGA processor in any Slot 1 board. A typical slot-ket adapter is shown in the “Celeron” section, later in this chapter.

▶▶ See “Celeron,” p. 159.

Socket 423

Socket 423 is a ZIF-type socket introduced in November 2000 for the Pentium 4, codenamed Willamette. Figure 3.20 shows Socket 423.

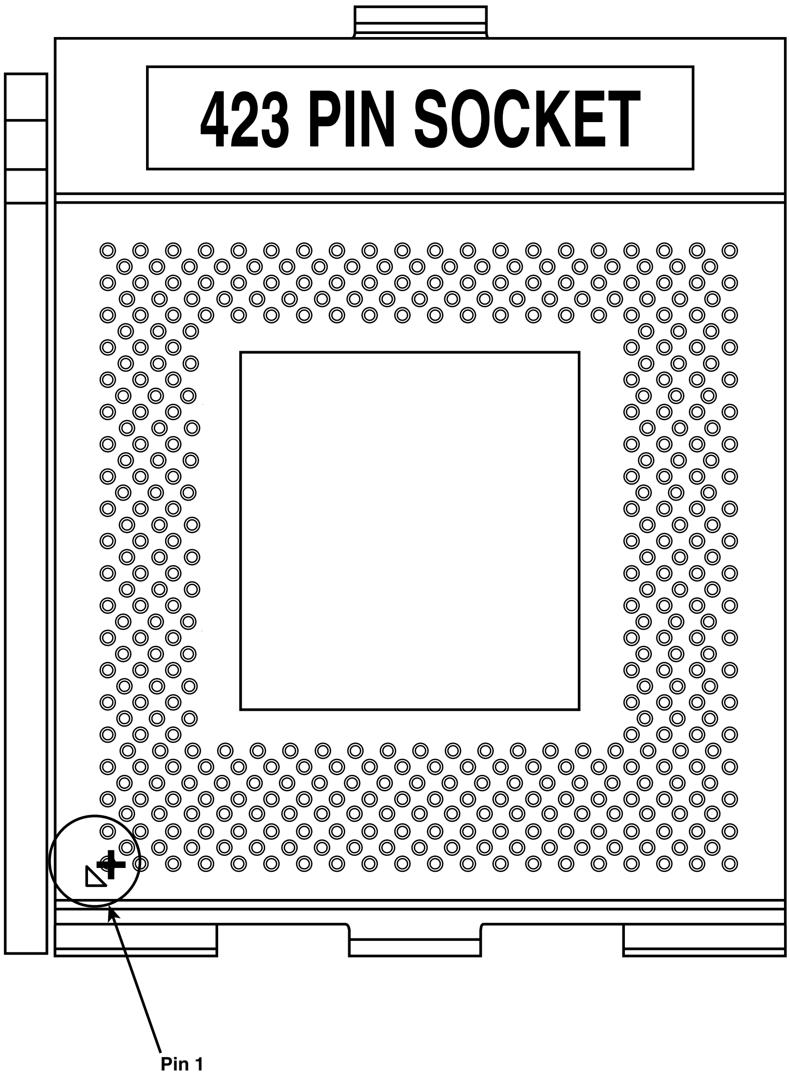

Figure 3.20 Socket 423 (Pentium 4) showing pin 1 location.

Socket 423 supports a 400MHz processor bus, which connects the processor to the Memory Controller Hub (MCH), which is the main part of the motherboard chipset. Five voltage ID (VID) pins are used by the processor to signal the VRM built into the motherboard to deliver the correct voltage for the particular CPU you install. This makes the voltage selection completely automatic and foolproof. The initial Pentium 4 processors require 1.7 volts, but that might change for newer processors. A small triangular mark indicates the pin-1 corner for proper orientation of the chip.

Socket A (Socket 462)

AMD introduced Socket A, also called Socket 462, in June 2000 to support the PGA versions of the Athlon and Duron processors. It is designed as a replacement for Slot A used by the original Athlon processor. Because the Athlon has now moved to incorporate L2 cache on-die, and the new Duron is available only in an on-die cache version, there was no longer a need for the expensive cartridge packaging used by the original Athlon processors.

Socket A has 462 pins and 11 plugs oriented in an SPGA form (see Figure 3.21). Socket A has the same physical dimensions and layout as Socket 370; however, the location and placement of the plugs prevent Socket 370 processors from being inserted. Socket A supports 32 voltage levels from 1.100V to 1.850V in 0.025V increments, controlled by the VID0-VID4 pins on the processor. The automatic voltage regulator module circuitry typically is embedded on the motherboard.

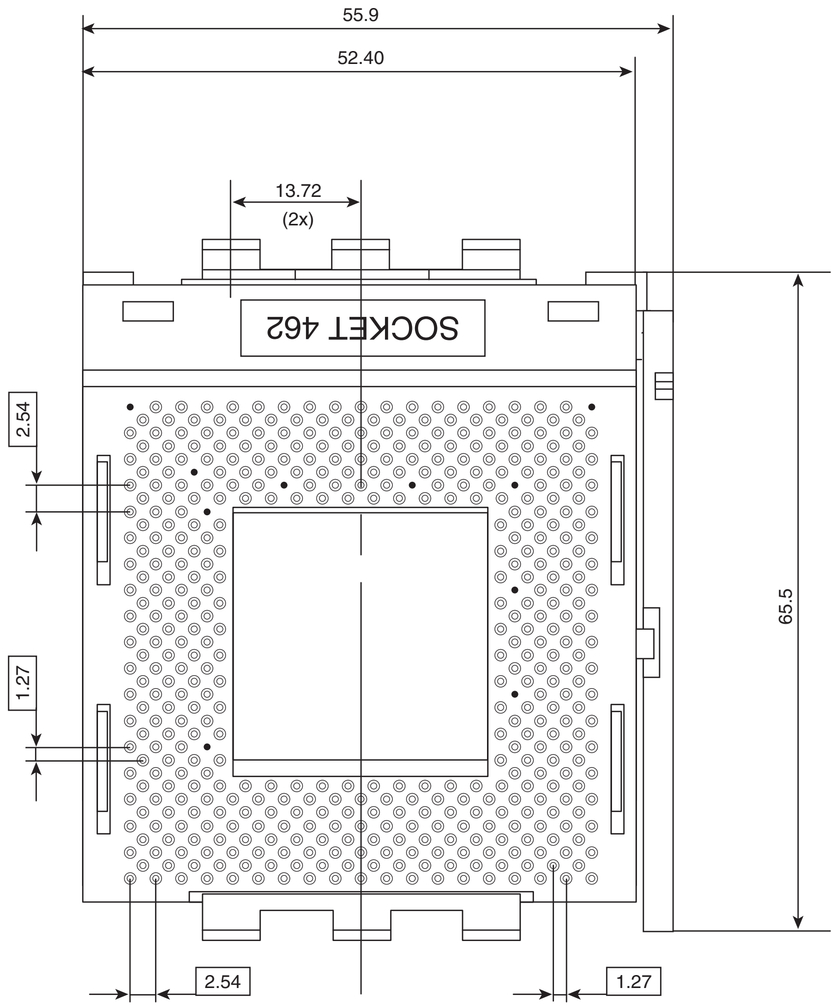

Figure 3.21 Socket A (Socket 462) Athlon/Duron layout.

There are 11 total plugged holes, including 2 of the outside pin holes at A1 and AN1. These are used to allow for keying to force the proper orientation of the processor in the socket. The pinout of Socket A is shown in Figure 3.22.

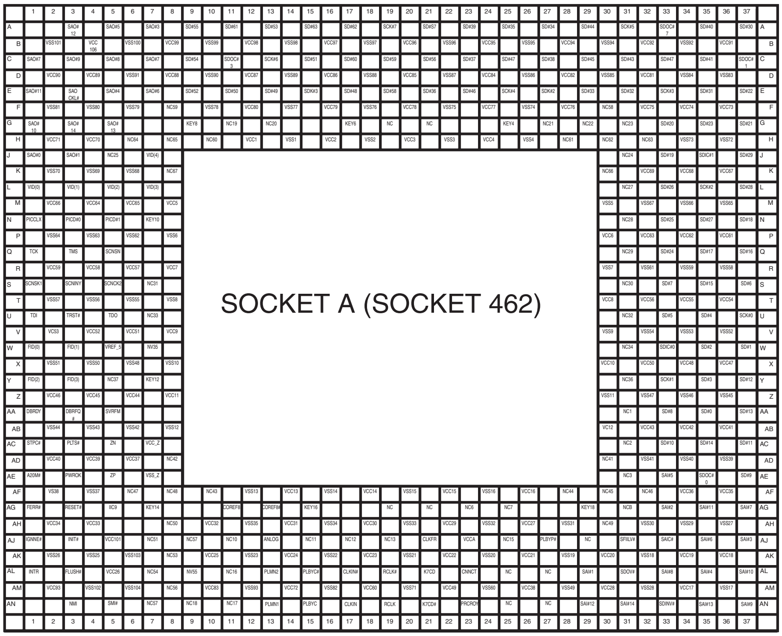

Figure 3.22 Socket A (Socket 462) Athlon/Duron pinout (top view).

AMD has indicated that all future Athlon and Duron processors, at least for the time being, will be made in Socket A form, and the Slot A versions of the Athlon will be phased out.

Zero Insertion Force Sockets

When the Socket 1 specification was created, manufacturers realized that if users were going to upgrade processors, they had to make the process easier. The socket manufacturers found that it typically takes 100 lbs. of insertion force to install a chip in a standard 169-pin screw Socket 1 motherboard. With this much force involved, you easily could damage either the chip or socket during removal or reinstallation. Because of this, some motherboard manufacturers began using low insertion force (LIF) sockets, which typically required only 60 lbs. of insertion force for a 169-pin chip. With the LIF or standard socket, I usually advise removing the motherboard—that way you can support the board from behind when you insert the chip. Pressing down on the motherboard with 60–100 lbs. of force can crack the board if it is not supported properly. A special tool is also required to remove a chip from one of these sockets. As you can imagine, even the low insertion force was relative, and a better solution was needed if the average person was going to ever replace his CPU.

Manufacturers began inserting special ZIF sockets in their later Socket 1 motherboard designs. Since then, virtually all processor sockets have been of the ZIF design. Note, however, that a given Socket X specification has nothing to do with whether it is ZIF, LIF, or standard; the socket specification covers only the pin arrangement. Since the 486 era, nearly all motherboard manufacturers have been using ZIF sockets. These sockets almost eliminate the risk involved in upgrading because no insertion force is necessary to install the chip and no tool is need to extract one. Most ZIF sockets are handle-actuated; you lift the handle, drop the chip into the socket, and then close the handle. This design makes replacing the original processor with the upgrade processor an easy task.

Processor Slots

After introducing the Pentium Pro with its integrated L2 cache, Intel discovered that the physical package it chose was very costly to produce. Intel was looking for a way to easily integrate cache and possibly other components into a processor package, and it came up with a cartridge or board design as the best way to do this. To accept its new cartridges, Intel designed two types of slots that could be used on motherboards.

Slot 1 is a 242-pin slot designed to accept Pentium II, Pentium III, and most Celeron processors. Slot 2, on the other hand, is a more sophisticated 330-pin slot designed for the Pentium II and III Xeon processors, which are primarily for workstations and servers. Besides the extra pins, the biggest difference between Slot 1 and Slot 2 is the fact that Slot 2 was designed to host up to four-way or more processing in a single board. Slot 1 allows only single or dual processing functionality.

Note that Slot 2 is also called SC330, which stands for slot connector with 330 pins.

Slot 1 (SC242)

Slot 1, also called SC242 (slot connector 242 pins), is used by the SEC design used with the cartridge-type Pentium II/III and Celeron processors (see Figure 3.23).

◀◀ See "Single Edge Contact and Single Edge Processor Packaging," p. 80.

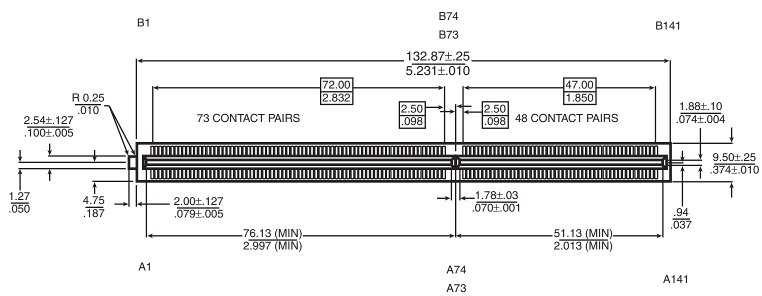

Figure 3.23 Slot 1 connector dimensions and pin layout.

Slot 2 (SC330)

Slot 2, otherwise called SC330 (slot connector 330 pins) is used on high-end motherboards that support the Pentium II and III Xeon processors. Figure 3.24 shows the Slot 2 connector.

The Xeon processors are designed in a cartridge similar to, but larger than, that used for the standard Pentium II/III. Figure 3.25 shows the Xeon cartridge.

Motherboards featuring Slot 2 are found primarily in higher-end systems, such as workstations or servers, which use the Xeon processors. These are Intel's high-end chips, which differ from the standard Pentium II/III mainly by virtue of having full-core speed L2 cache, and in some versions more of it. The additional pins allow for additional signals needed by multiple processors.

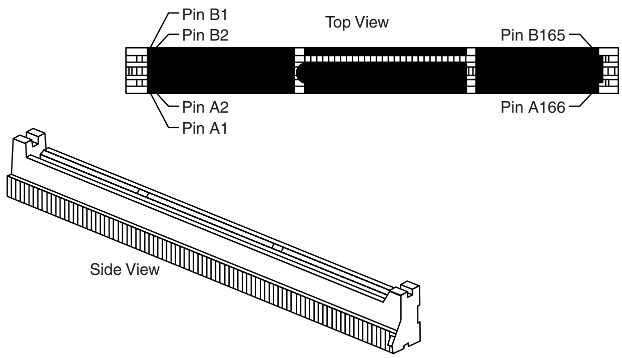

Figure 3.24 Slot 2 (SC330) connector dimensions and pin layout.

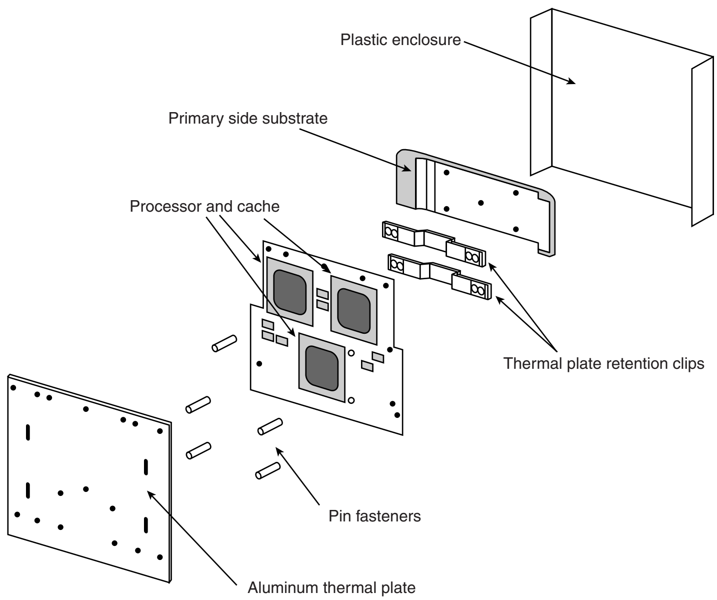

Figure 3.25 Pentium II/III Xeon cartridge.

CPU Operating Voltages

One trend that is clear to anybody who has been following processor design is that the operating voltages have gotten lower and lower. The benefits of lower voltage are threefold. The most obvious is that with lower voltage comes lower overall power consumption. By consuming less power, the system is less expensive to run, but more importantly for portable or mobile systems, it runs much longer on existing battery technology. The emphasis on battery operation has driven many of the advances in lowering processor voltage because this has a great effect on battery life.

The second major benefit is that with less voltage and therefore less power consumption, less heat is produced. Processors that run cooler can be packed into systems more tightly and last longer. The third major benefit is that a processor running cooler on less power can be made to run faster. Lowering the voltage has been one of the key factors in enabling the clock rates of processors to go higher and higher.

Until the release of the mobile Pentium and both desktop and mobile Pentium MMX, most processors used a single voltage level to power both the core as well as run the input/output circuits. Originally, most processors ran both the core and I/O circuits at 5 volts, which was later was reduced to 3.5 or 3.3 volts to lower power consumption. When a single voltage is used for both the internal processor core power as well as the external processor bus and I/O signals, the processor is said to have a single or unified power plane design.

When originally designing a version of the Pentium processor for mobile or portable computers, Intel came up with a scheme to dramatically reduce the power consumption while still remaining compatible with the existing 3.3v chipsets, bus logic, memory, and other components. The result was a dual-plane or split-plane power design in which the processor core ran off a lower voltage while the I/O circuits remained at 3.3v. This originally was called voltage reduction technology (VRT) and first debuted in the Mobile Pentium processors released in 1996. Later, this dual-plane power design also appeared in desktop processors such as the Pentium MMX, which used 2.8v to power the core and 3.3v for the I/O circuits. Now most recent processors, whether for mobile or desktop use, feature a dual-plane power design. Some of the more recent Mobile Pentium II processors run on as little as 1.6v for the core while still maintaining compatibility with 3.3v components for I/O.

Knowing the processor voltage requirements is not a big issue with Socket 8, Socket 370, Socket A, Pentium Pro (Socket 8), or Pentium II (Slot 1 or Slot 2) processors because these sockets and slots have special VID pins the processor uses to signal to the motherboard the exact voltage requirements. This enables the voltage regulators built into the motherboard to be automatically set to the correct voltage levels by merely installing the processor.

Unfortunately, this automatic voltage setting feature is not available on Socket 7 and earlier motherboard and processor designs. Therefore, you usually must set jumpers or otherwise configure the motherboard according to the voltage requirements of the processor you are installing. Pentium (Socket 4, 5, or 7) processors have run on a number of voltages, but the latest MMX versions are all 2.8v—except for mobile Pentium processors, which are as low as 1.8v. Table 3.12 lists the voltage settings used by Intel Pentium (non-MMX) processors that use a single power plane. This means that both the CPU core and the I/O pins run at the same voltage.

Table 3.13 shows voltages used by Socket 7 processors.

Table 3.13 Socket 7 Single- and Dual-Plane Processor Voltages

Voltage Setting	Processor	Core Voltage	I/O Voltage	Voltage Planes
VRE (3.5v)	Intel Pentium	3.5v	3.5v	Single
STD (3.3v)	Intel Pentium	3.3v	3.3v	Single
MMX (2.8v)	Intel MMX Pentium	2.8v	3.3v	Dual
VRE (3.5v)	AMD K5	3.5v	3.5v	Single
3.2v	AMD-K6	3.2v	3.3v	Dual
2.9v	AMD-K6	2.9v	3.3v	Dual
2.4v	AMD-K6-2/K6-3	2.4v	3.3v	Dual
2.2v	AMD-K6/K6-2	2.2v	3.3v	Dual
VRE (3.5v)	Cyrix 6x86	3.5v	3.5v	Single
2.9v	Cyrix 6x86MX/M-II	2.9v	3.3v	Dual
MMX (2.8v)	Cyrix 6x86L	2.8v	3.3v	Dual
2.45v	Cyrix 6x86LV	2.45v	3.3v	Dual

Normally, the acceptable range is plus or minus 5% from the nominal intended setting.

Most Socket 7 and later Pentium motherboards supply several voltages (such as 2.5v, 2.7v, 2.8v, and 2.9v) for compatibility with future devices. A voltage regulator built into the motherboard converts the power supply voltage into the various levels required by the processor core. Check the documentation for your motherboard and processor to find the appropriate settings.

The Pentium Pro and Pentium II processors automatically determine their voltage settings by controlling the motherboard-based voltage regulator through built-in VID pins. Those are explained in more detail later in this chapter.

▶▶ See "Pentium Pro Processors," p. 143.

▶▶ See "Pentium II Processors," p. 147.

Note that on the STD or VRE settings, the core and I/O voltages are the same; these are single-plane voltage settings. Any time a voltage other than STD or VRE is set, the motherboard defaults to a dual-plane voltage setting where the core voltage can be specifically set, while the I/O voltage remains constant at 3.3v no matter what.

Socket 5 was designed to supply only STD or VRE settings, so any processor that can work at those settings can work in Socket 5 as well as Socket 7. Older Socket 4 designs can supply only 5v, plus they have a completely different pinout (fewer pins overall), so using a processor designed for Socket 7 or Socket 5 in Socket 4 is not possible.

Most Socket 7 and later Pentium motherboards supply several voltages (such as 2.2v, 2.4v, 2.5v, 2.7v, 2.8v, and 2.9v as well as the older STD or VRE settings) for compatibility with many processors. A voltage regulator built into the motherboard converts the power supply voltage into the various levels required by the processor core. Check the documentation for your motherboard and processor to find the appropriate settings.

The Pentium Pro, Celeron, and Pentium II/III processors automatically determine their voltage settings by controlling the motherboard-based voltage regulator. That's done through built-in VID pins.

For hotrodding purposes, many newer motherboards for these processors have override settings that allow for manual voltage adjustment if desired. Many people have found that when attempting to overclock a processor, increasing the voltage by a tenth of a volt or so often helps. Of course, this increases the heat output of the processor and must be accounted for with adequate heatsinking.

Heat and Cooling Problems

Heat can be a problem in any high-performance system. The higher-speed processors typically consume more power and therefore generate more heat. The processor is usually the single most power-hungry chip in a system, and in most situations, the fan inside your computer case might not be capable of handling the load without some help.

Heatsinks

To cool a system in which processor heat is a problem, you can buy (for less than $5, in most cases) a special attachment for the CPU chip called a *heatsink*, which draws heat away from the CPU chip. Several heatsink manufacturers are listed in the Vendor List on the CD.

A heatsink works like the radiator in your car, pulling heat away from the engine. In a similar fashion, the heatsink conducts heat away from the processor so it can be vented out of the system. It does this by using a thermal conductor (usually metal) to carry heat away from the processor into fins that expose a high amount of surface area to moving air. This enables the air to be heated, thus cooling the heatsink and the processor as well. Just like the radiator in your car, the heatsink depends on airflow. With no moving air, a heatsink is incapable of radiating the heat away. To keep the engine in your car from overheating when the car is not moving, auto engineers incorporate a fan. Likewise, there is always a fan somewhere inside your PC helping to move air across the heatsink and vent it out of the system. Sometimes the fan included in the power supply is enough; other times an additional fan must be added to the case, or even directly over the processor to provide the necessary levels of cooling.

The heatsink is clipped or glued to the processor. A variety of heatsinks and attachment methods exist. Figure 3.26 shows various passive heatsinks and attachment methods.

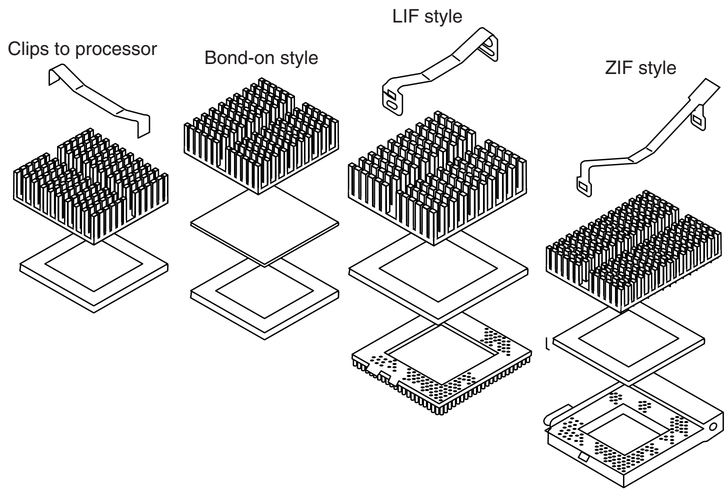

Figure 3.26 Passive heatsinks for socketed processors showing various attachment methods.

Tip

According to data from Intel, heatsink clips are the number-two destroyer of motherboards (screwdrivers are number one). When installing or removing a heatsink that is clipped on, be sure you don't scrape the surface of the motherboard. In most cases, the clips hook over protrusions in the socket, and when installing or removing the clips, scratching or scraping the surface of the board right below where the clip ends attach is very easy. I like to place a thin sheet of plastic underneath the edge of the clip while I work, especially if board traces that can be scratched are in the vicinity.

Heatsinks are rated for their cooling performances. Typically, the ratings are expressed as a resistance to heat transfer, in degrees centigrade per watt (°C/W), where lower is better. Note that the resistance varies according to the airflow across the heatsink. To ensure a constant flow of air and more consistent performance, many heatsinks incorporate fans so they don't have to rely on the airflow within the system. Heatsinks with fans are referred to as *active* heatsinks (see Figure 3.27). Active heatsinks have a power connection, often using a spare disk drive power connector, although most newer motherboards now have dedicated heatsink power connections right on the board.

Active heatsinks use a fan or other electric cooling device, which requires power to run. The fan type is most common but some use a peltier cooling device, which is basically a solid-state refrigerator. Active heatsinks require power and normally plug into a disk drive power connector or special 12v fan power connectors on the motherboard. If you do get a fan-type heatsink, be aware that some on the market are very poor quality. The bad ones have motors that use sleeve bearings, which freeze up after a very short life. I recommend only fans with ball-bearing motors, which last about 10 times longer than the sleeve-bearing types. Of course, they cost more—but only about twice as much, so you'll save money in the long run.

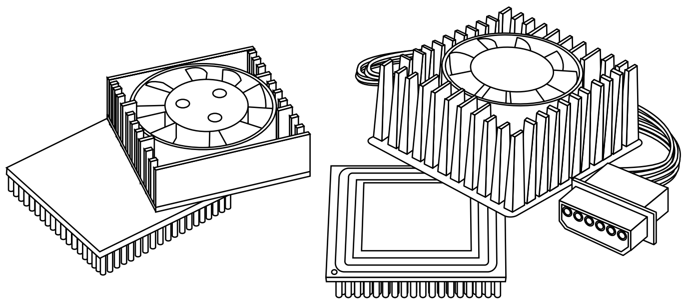

Figure 3.27 Active heatsinks for socketed processors.

Figure 3.28 shows an active heatsink arrangement on a Pentium II/III type processor. This is common on what Intel calls its "boxed processors," which are sold individually and through dealers.

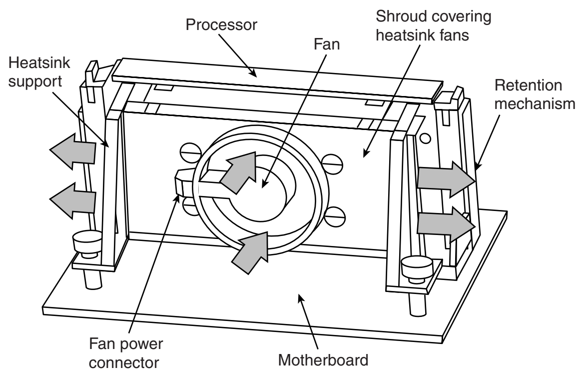

Figure 3.28 An active (fan-powered) heatsink and supports used with Pentium II/III–type processors.

The passive heatsinks are 100% reliable because they have no mechanical components to fail. *Passive* heatsinks are basically aluminum-finned radiators that dissipate heat through convection (see Figure 3.29). Passive types don't work well unless there is some airflow across the fins, usually provided by the power supply fan or an extra fan in the case. If your case or power supply is properly designed, you can use a less-expensive passive heatsink instead of an active one.

Tip

To function effectively, a heatsink must be as directly attached to the processor as possible. To eliminate air gaps and ensure a good transfer of heat, in most cases, you should put a thin coating of thermal transfer grease on the surface of the processor where the heatsink attaches. This dramatically decreases the thermal resistance properties and is required for maximum performance.

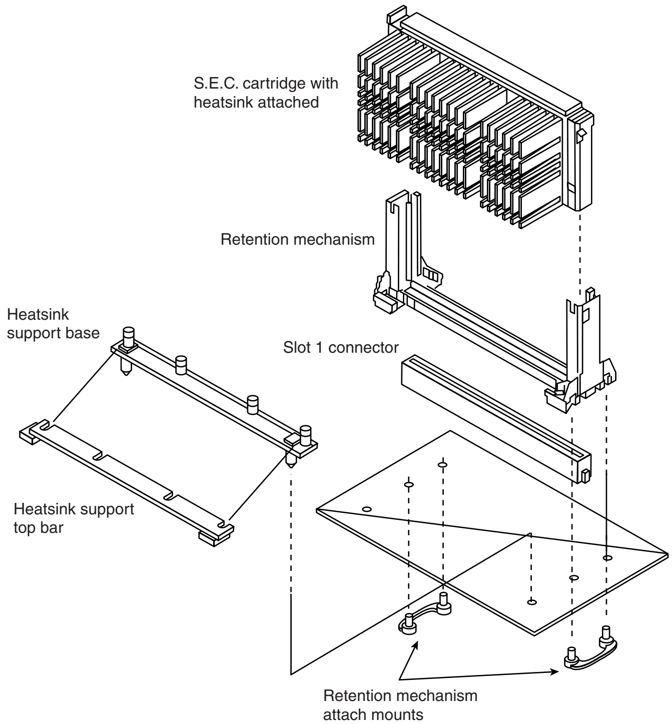

Figure 3.29 A passive heatsink and supports used with Pentium II/III–type processors.

To have the best possible transfer of heat from the processor to the heatsink, most heatsink manufacturers specify some type of thermal interface material to be placed between the processor and the heatsink. This normally consists of a zinc-based white grease (similar to what skiers put on their noses to block the sun) but can also be a special pad or even a type of double-stick tape. Using a thermal interface aid such as thermal grease can improve heatsink performance dramatically. Figure 3.30 shows the thermal interface pad or grease positioned between the processor and heatsink.

You can purchase thermal paste in small single-use tubes or larger versions that can service multiple processor installations.

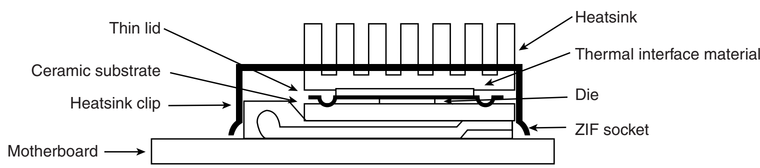

Figure 3.30 Thermal interface material helps transfer heat from the processor die to the heatsink.

Most of the newer systems on the market use an improved motherboard form factor (shape) design called ATX. Systems made from this type of motherboard and case allow for improved cooling of the processor because of the processor being repositioned in the case near the power supply. Also, most of these cases now feature a secondary fan to further assist in cooling. The larger case-mounted fans typically are more reliable than the smaller fans included in active heatsinks. A properly designed case can move sufficient air across the processor, enabling a more reliable and less-expensive passive (no fan) heatsink to be used.

Math Coprocessors (Floating-Point Units)

This section covers the floating-point unit (FPU) contained in the processor, which was formerly a separate external math coprocessor in the 386 and older chips. Older central processing units designed by Intel (and cloned by other companies) used an external math coprocessor chip. However, when Intel introduced the 486DX, it included a built-in math coprocessor, and every processor built by Intel (and AMD and Cyrix, for that matter) since then includes a math coprocessor. Coprocessors provide hardware for floating-point math, which otherwise would create an excessive drain on the main CPU. Math chips speed your computer's operation only when you are running software designed to take advantage of the coprocessor. All the subsequent fifth- and sixth-generation Intel and compatible processors (such as those from AMD and Cyrix) have featured an integrated floating-point unit.

Math chips (as coprocessors sometimes are called) can perform high-level mathematical operations—long division, trigonometric functions, roots, and logarithms, for example—at 10–100 times the speed of the corresponding main processor. The operations performed by the math chip are all operations that make use of noninteger numbers (numbers that contain digits after the decimal point). The need to process numbers in which the decimal is not always the last character leads to the term *floating point* because the decimal (point) can move (float), depending on the operation. The integer units in the primary CPU work with integer numbers, so they perform addition, subtraction, and multiplication operations. The primary CPU is designed to handle such computations; these operations are not offloaded to the math chip.

The instruction set of the math chip is different from that of the primary CPU. A program must detect the existence of the coprocessor and then execute instructions written explicitly for that coprocessor; otherwise, the math coprocessor draws power and does nothing else. Fortunately, most modern programs that can benefit from the use of the coprocessor correctly detect and use the coprocessor. These programs usually are math intensive: spreadsheet programs, database applications, statistical programs, and graphics programs, such as computer-aided design (CAD) software. Word processing programs do not benefit from a math chip and therefore are not designed to use one. Table 3.14 summarizes the coprocessors available for the Intel family of processors.

Table 3.14 Math Coprocessor Summary

Processor	Coprocessor
8086	8087
8088	8087
286	287
386SX	387SX
386DX	387DX
486SX	487SX, DX2/OverDrive[1]
487SX[1]	Built-in FPU
486SX2	DX2/OverDrive[2]
486DX	Built-in FPU

Table 3.14 Continued

Processor	Coprocessor
486DX2	Built-in FPU
486DX4/5x86	Built-in FPU
Intel Pentium/Pentium MMX	Built-in FPU
Cyrix 6x86/MI/MII	Built-in FPU
AMD K5/K6/Athlon/Duron	Built-in FPU
Pentium II/III/Celeron/Xeon	Built-in FPU
Pentium 4	Built-in FPU
Itanium	Built-in FPU

FPU = Floating-point unit

1. *The 487SX chip is a modified pinout 486DX chip with the math coprocessor enabled. When you plug in a 487SX chip, it disables the 486SX main processor and takes over all processing.*
2. *The DX2/OverDrive is equivalent to the SX2 with the addition of a functional FPU.*

Although virtually all processors since the 486 series have built-in floating-point units, they vary in performance. Historically, the Intel processor FPUs have dramatically outperformed those from AMD and Cyrix, although AMD and Cyrix are achieving performance parity in their newer offerings.

Within each of the original 8087 group, the maximum speed of the math chips varies. A suffix digit after the main number, as shown in Table 3.15, indicates the maximum speed at which a system can run a math chip.

Table 3.15 Maximum Math Chip Speeds

Part	Speed	Part	Speed
8087	5MHz	287	6MHz
8087-3	5MHz	287-6	6MHz
8087-2	8MHz	287-8	8MHz
8087-1	10MHz	287-10	10MHz

The 387 math coprocessors and the 486 or 487 and Pentium processors always indicate their maximum speed ratings in MHz in the part number suffix. A 486DX2-66, for example, is rated to run at 66MHz. Some processors incorporate clock multiplication, which means they can run at different speeds compared with the rest of the system.

Tip

The performance increase in programs that use the math chip can be dramatic—usually, a geometric increase in speed occurs. If the primary applications you use can take advantage of a math coprocessor, you should upgrade your system to include one.

Most systems that use the 386 or earlier processors are socketed for a math coprocessor as an option, but they do not include a coprocessor as standard equipment. A few systems on the market at that time didn't even have a socket for the coprocessor because of cost and size considerations. These systems were usually low-cost or portable systems, such as older laptops, the IBM PS/1, and the PCjr. For more specific information about math coprocessors, see the discussions of the specific chips—8087, 287, 387, and 487SX—in the later sections. Table 3.16 shows the specifications of the various math coprocessors.

Table 3.16 Older Intel Math Coprocessor Specifications

Name	Power Consumption	Case Minimum Temperature	Case Maximum Temperature	No. of Transistors	Date Introduced
8087	3 watts	0°C, 32°F	85°C, 185°F	45,000	1980
287	3 watts	0°C, 32°F	85°C, 185°F	45,000	1982
287XL	1.5 watts	0°C, 32°F	85°C, 185°F	40,000	1990
387SX	1.5 watts	0°C, 32°F	85°C, 185°F	120,000	1988
387DX	1.5 watts	0°C, 32°F	85°C, 185°F	120,000	1987

Most often, you can learn which CPU and math coprocessor are installed in a particular system by checking the markings on the chip.

Processor Bugs

Processor manufacturers use specialized equipment to test their own processors, but you have to settle for a little less. The best processor-testing device to which you have access is a system that you know is functional; you then can use the diagnostics available from various utility software companies or your system manufacturer to test the motherboard and processor functions.

Companies such as Diagsoft, Symantec, Micro 2000, Trinitech, Data Depot, and others offer specialized diagnostics software that can test the system, including the processor. If you don't want to purchase this type of software, you can perform a quick-and-dirty processor evaluation by using the diagnostics program supplied with your system.

Perhaps the most infamous of these bugs is the floating-point division math bug in the early Pentium processors. This and a few other bugs are discussed in detail later in this chapter.

Because the processor is the brain of a system, most systems don't function with a defective processor. If a system seems to have a dead motherboard, try replacing the processor with one from a functioning motherboard that uses the same CPU chip. You might find that the processor in the original board is the culprit. If the system continues to play dead, however, the problem is elsewhere, most likely in the motherboard, memory, or power supply. See the chapters that cover those parts of the system for more information on troubleshooting those components. I must say that in all my years of troubleshooting and repairing PCs, I have rarely encountered defective processors.

A few system problems are built in at the factory, although these bugs or design defects are rare. By learning to recognize these problems, you can avoid unnecessary repairs or replacements. Each processor section describes several known defects in that generation of processors, such as the infamous floating-point error in the Pentium. For more information on these bugs and defects, see the following sections, and check with the processor manufacturer for updates.

Processor Update Feature

All processors can contain design defects or errors. Many times, the effects of any given bug can be avoided by implementing hardware or software workarounds. Intel documents these bugs and workarounds well for its processors in its processor Specification Update manual; this manual is available from Intel's Web site. Most of the other processor manufacturers also have bulletins or tips on their Web sites listing any problems or special fixes or patches for their chips.

Previously, the only way to fix a processor bug was to work around it or replace the chip with one that had the bug fixed. Now, a new feature built into the Intel P6 processors, including the Pentium Pro through Pentium III and Celeron, can allow many bugs to be fixed by altering the *microcode* in the processor. Microcode is essentially a set of instructions and tables in the processor that control how the processor operates. These processors incorporate a new feature called *reprogrammable microcode*, which enables certain types of bugs to be worked around via microcode updates. The microcode updates reside in the system ROM BIOS and are loaded into the processor by the system BIOS during the POST. Each time the system is rebooted, the fix code is reloaded, ensuring that it will have the bug fix installed anytime the processor is operating.

The easiest method for checking the microcode update is to use the processor update utility, which is developed and supplied by Intel. This utility can verify whether the correct update is present. The utility displays the processor *stepping* and version of the microcode update. A stepping is the processor hardware equivalent of a new version. In software, we refer to minor version changes as 1.0, 1.1, 1.2, and so on, whereas in processors we call these minor revisions steppings.

To install a new microcode update, however, the motherboard BIOS must contain the routines to support the microcode update, which virtually all Pentium Pro and Pentium II BIOSes do have. The Intel processor update utility determines whether the code is present in the BIOS, compares the processor stepping with the microcode update currently loaded, and installs the new update, if necessary. Use of this utility with motherboards containing the BIOS microcode update routine allows just the microcode update data to be changed; the rest of the BIOS is unchanged. A version of the update utility is provided with all Intel boxed processors. The term *boxed processors* refers to processors packaged for use by system integrators—that is, people who build systems. If you want the most current version of this utility, you must contact an Intel processor dealer to download it because Intel supplies it only to its dealers.

Note that if the BIOS in your motherboard does not include the processor microcode update routine, you should get a complete system BIOS upgrade from the motherboard vendor.

You can use the processor update utility to check that the system BIOS contains microcode updates specific to the particular silicon stepping of the processor you are installing. In other words, you must ensure that the update matches the processor stepping being used.

Table 3.17 contains the current microcode update revision for each processor stepping. These update revisions are contained in the microcode update database file that comes with the Pentium Pro processor and Pentium II processor update utility. Processor steppings are listed in the sections on the Pentium, Pentium Pro, and Pentium II processors later in this chapter.

Table 3.17 Processor Steppings (Revisions) and Microcode Update Revisions Supported by the Update Database File *PEP6.PDB*

Processor	Stepping	Stepping Signature	Microcode Update Revision Required
Pentium Pro	C0	0x612	0xC6
Pentium Pro	sA0	0x616	0xC6
Pentium Pro	sA1	0x617	0xC6
Pentium Pro	sB1	0x619	0xD1
Pentium II	C0	0x633	0x32
Pentium II	C1	0x634	0x33
Pentium II	dA0	0x650	0x15

Using the processor update utility (CHECKUP3.EXE) available from Intel, a system builder easily can verify that the correct microcode update is present in all systems based on the P6 (Pentium Pro, Celeron, Pentium II/III) processors. For example, if a system contains a processor with stepping C1 and stepping signature 0x634, the BIOS should contain the microcode update revision 0x33. The processor update utility identifies the processor stepping, signature, and microcode update revision that is currently in use.

If a new microcode update needs to be installed in the system BIOS, the system BIOS must contain the Intel-defined processor update routines so the processor update utility can permanently install the latest update. Otherwise, a complete system BIOS upgrade is required from the motherboard manufacturer. It is recommended that the processor update utility be run after upgrading a motherboard BIOS and before installing the operating system when building a system based on any P6 processor. The utility is easy to use and executes in just a few seconds. Because the update utility might need to load new code into your BIOS, ensure that any jumper settings on the motherboard are placed in the "enable flash upgrade" position. This enables writing to the flash memory.

After running the utility, turn off power to the system and reboot—do not warm boot—to ensure that the new update is correctly initialized in the processor. Also ensure that all jumpers, such as any flash upgrade jumpers, and so on, are returned to their normal positions.

Both Intel and AMD have a number of useful utilities available for downloading from their Web sites, utilities that can be very useful for somebody who is building a system. These include utilities that identify exactly which processor you have, the speed the processor is running at, in some cases whether it has been overclocked, and even useful information such as processor temperature, steppings, and more.

In addition to software utilities, both Intel and AMD have extensive technical documentation libraries online, all free for downloading. These documents range from the actual processor and chipset data books to motherboard schematics, design guides, and even information about cooling and thermal requirements.

Processor Codenames

Intel, AMD, and Cyrix have always used codenames when talking about future processors. The codenames usually are not supposed to become public, but often they do. They can often be found in magazine articles talking about future-generation processors. Sometimes, they even appear in motherboard manuals because the manuals are written before the processors are officially introduced. Table 3.18 lists processor codenames for reference purposes.

Table 3.18 Processors and Codenames

AMD Codename	AMD Processor
X5	5x86-133 [Socket 3]
SSA5	K5 (PR75-100) [Socket 5, 7]
5k86	K5 (PR120-200) [Socket 7]
K6	Original K6 core; killed after AMD acquired NexGen
NX686	NexGen core that became the K6 [Socket 7]
Little Foot	0.25µ K6 [Socket 7]
Chompers	K6-2 (formerly K6-3D) [Socket 7, Super 7]
Sharptooth	K6-3 (formerly K6 Plus-3D) [Super 7]
Argon	Original codename for K7

Table 3.18 Continued

AMD Codename	AMD Processor
K7	Athlon [Slot A]
K75	0.18µ Athlon [Slot A]
Spitfire	Duron [Socket A]
Thunderbird	Athlon [Slot A, Socket A]
Mustang	Athlon w/copper interconnects [Slot A, Socket A]
Corvette	Mobile Athlon [Socket A]
SledgeHammer	K8 (64-bit CPU)
Cyrix Codename	**Cyrix Processor**
M6	486DX [Socket 1, 2, 3]
M7	486DX2/DX4 [Socket 3]
M9	5x86 [Socket 3]
M1sc	5x86 [Socket 3]
Chili	5x86 project
M1	6x86 (3.3v or 3.52v version) [Socket 7]
M1L	6x86L (2.8v/3.3v split version) [Socket 7]
M1R	Switch from 3M SGS process to 5M IBM process for 6x86
M2	6x86MX/M-II [Socket 7, Super 7]
Cayenne	MXi and Gobi core
Jedi	Original codename for Joshua (before Gobi)
Gobi	Former codename for Joshua
Joshua	VIA/Cyrix-III [Socket 370]
Jalapeno	Former codename for Mojave
Mojave	Cyrix/VIA M3 [Socket 370]
Serrano	Cyrix/VIA M4
C5	Samuel core (Winchip-4 plus on-die L2 cache)
Samuel	Cyrix/VIA chip based on Winchip-4 [Socket 370]
Intel Codename	**Intel Processor**
P23	486SX [Socket 1, 2, 3]
P23S	486SX SL-enhanced [Socket 1, 2, 3]
P23N	487SX (coprocessor) [Socket 1]
P4	486DX [Socket 1, 2, 3]
P4S	486DX SL-enhanced [Socket 1, 2, 3]
P24	486DX2 [Socket 1, 2, 3]
P24S	486DX2 SL-enhanced [Socket 1, 2, 3]
P24D	486DX2 (write-back enhanced version) [Socket 3]
P24C	486DX4 [Socket 3]
P23T	486DXODP (486 OverDrive) [Socket 1, 2, 3]
P4T	486DXODPR (486 OverDrive) [Socket 1, 2, 3]

Table 3.18 Continued

Intel Codename	Intel Processor
P24T	PODP5V (Pentium OverDrive for 486) [Socket 2, 3]
P24CT	Pentium OverDrive for 486DX4 (3.3v core) [Socket 2, 3]
P5	Pentium (60/66MHz versions) [Socket 4]
P5T	Pentium OverDrive (120, 133) [Socket 4]
P54C	Pentium (75–120MHz versions) [Socket 5, 7]
P54CQS	Pentium (120–133MHz version) [Socket 5, 7]
P54CS	Pentium (120–200MHz versions) [Socket 7]
P54CTA	Pentium OverDrive (125, 150, 166) [Socket 5, 7]
P55C	Pentium MMX [Socket 7]
P54CTB	Pentium MMX OverDrive [Socket 5, 7]
Tillamook	Mobile Pentium MMX
P6	Pentium Pro [Socket 8]
P6T	Pentium II OverDrive [Socket 8]
Klamath	Pentium II [Slot 1]
Drake	Pentium II Xeon [Slot 2]
Deschutes	0.25µ Pentium II [Slot 1 & 2]
Tonga	Mobile Pentium II
Covington	Celeron (cacheless Deschutes) [Slot 1]
Mendocino	Celeron (128KB on-die L2) [Slot 1, Socket 370]
Dixon	Mobile Pentium II (256KB on-die L2)
Katmai	Pentium III [Slot 1]
Tanner	Pentium III Xeon [Slot 2]
Coppermine	0.18µ PIII w/256KB on-die L2 [Slot 1, Socket 370]
Tualatin	0.13µ PIII
Cascades	Coppermine Xeon (256KB on-die L2) [Slot 2]
Coppermine-128	Celeron III (128KB on-die L2) [Socket 370]
Timna	Celeron III w/integral chipset hub
P68	Former codename for Willamette
Willamette	Pentium 4 [Socket 423]
Foster	Pentium 4 Xeon [Socket 603]
Prestonia	Successor to P4 Xeon
Gallatin	0.13µ successor to Foster [Socket 603]
Northwood	0.13 Pentium 4
P7	Former codename for Merced
Merced	Itanium (IA64) [PAC418]
McKinley	Second-generation Itanium [PAC418]
Madison	0.13µ McKinley [PAC418]
Deerfield	Low-cost Madison [PAC418]

Note that the codenames and information listed in these tables is not officially released, so by the time many of these future processors come out, names or specifications might change. Most companies who actually get this information from Intel are required to sign nondisclosure agreements that prevent them from sharing this information. This information has been gathered from a number of contacts and sources.

Intel-Compatible Processors (AMD and Cyrix)

Several companies—mainly AMD and Cyrix—have developed processors that are compatible with Intel processors. These chips are fully Intel compatible, so they emulate every processor instruction in the Intel chips. Many of the chips are also pin compatible, which means that they can be used in any system designed to accept an Intel processor; others require a custom motherboard design. Any hardware or software that works on Intel-based PCs will work on PCs made with these third-party CPU chips. A number of companies currently offer Intel-compatible chips, and some of the most popular ones are discussed here.

AMD Processors

Advanced Micro Devices (AMD) has become a major player in the Pentium-compatible chip market with its own line of Intel-compatible processors. AMD ran into trouble with Intel several years ago because its 486-clone chips used actual Intel microcode. These differences have been settled, and AMD now has a five-year cross-license agreement with Intel. In 1996, AMD finalized a deal to absorb NexGen, another maker of Intel-compatible CPUs. NexGen had been working on a chip it called the Nx686, which was renamed the K6 and introduced by AMD. Since then, AMD has refined the design as the K6-2 and K6-3. Its newest chips, called the Athlon and Duron, are designed similarly to the Pentium II/III and Celeron and use a similar but not identical slot and now socket design. AMD currently offers a wide variety of CPUs, from 486 upgrades to the K6 series and the Athlon/Duron.

Table 3.19 lists the basic processors offered by AMD.

Table 3.19 AMD CPU Summary

CPU Type	P-Rating	Actual CPU Speed (MHz)	Clock Multiplier	Motherboard Speed (MHz)	CPU Socket or Slot
Am486DX4-100	n/a	100	3x	33	Socket 1,2,3
Am486DX4-120	n/a	120	3x	40	Socket 1,2,3
Am5x86-133	75	133	4x	33	Socket 1,2,3
K5	PR75	75	1.5x	50	Socket 5,7
K5	PR90	90	1.5x	60	Socket 5,7
K5	PR100	100	1.5x	66	Socket 5,7
K5	PR120	90	1.5x	60	Socket 5,7
K5	PR133	100	1.5x	66	Socket 5,7
K5	PR166	116.7	1.75x	66	Socket 5,7
K6	PR166	166	2.5x	66	Socket 7
K6	PR200	200	3x	66	Socket 7
K6	PR233	233	3.5x	66	Socket 7
K6	PR266	266	4x	66	Socket 7
K6	PR300	300	4.5x	66	Socket 7
K6-2	PR233	233	3.5x	66	Socket 7

Table 3.19 Continued

CPU Type	P-Rating	Actual CPU Speed (MHz)	Clock Multiplier	Motherboard Speed (MHz)	CPU Socket or Slot
K6-2	PR266	266	4x	66	Socket 7
K6-2	PR300	300	4.5x	66	Socket 7
K6-2	PR300	300	3x	100	Super7
K6-2	PR333	333	5x	66	Socket 7
K6-2	PR333	333	3.5x	95	Super7
K6-2	PR350	350	3.5x	100	Super7

K6-3	PR450	450	4.5x	100	Super7
Athlon	PR500	500	2.5x	200	Slot A
Athlon/Duron	PR550	550	2.75x	200	Slot A/Socket A
Athlon/Duron	PR600	600	3x	200	Slot A/Socket A
Athlon/Duron	PR650	650	3.25x	200	Slot A/Socket A
Athlon/Duron	PR700	700	3.5x	200	Slot A/Socket A
Athlon/Duron	PR750	750	3.75x	200	Slot A/Socket A
Athlon/Duron	PR800	800	4x	200	Slot A/Socket A
Athlon/Duron	PR850	850	4.25x	200	Slot A/Socket A
Athlon/Duron	PR900	900	4.5x	200	Slot A/Socket A
Athlon/Duron	PR950	950	4.75x	200	Slot A/Socket A
Athlon/Duron	PR1000	1.0	5x	200	Slot A/Socket A
Athlon	PR1100	1.1	5.5x	200	Socket A
Athlon	PR1200	1.2	6x	200	Socket A
Athlon	PR1300	1.3	6.5x	200	Socket A
Athlon	PR1000	1.0	3.75x	266	Socket A
Athlon	PR1133	1.13	4.25x	266	Socket A
Athlon	PR1200	1.2	4.5x	266	Socket A
Athlon	PR1333	1.33	5x	266	Socket A

Notice in the table that for the K5 PR120 through PR166, the model designation does not match the CPU clock speed. This is called a PR rating instead and is further described earlier in this chapter.

Starting with the K6, the P-Rating equals the true MHz clock speed.

Most of the newer AMD Athlon and all Duron processors are designed to use Socket A, also called Socket 462.

Cyrix

Cyrix was purchased by National Semiconductor in November 1997 and by VIA Technologies in 1999. Prior to that, it had been a fabless company, meaning it had no chip-manufacturing capability. All the Cyrix chips were manufactured for Cyrix first by Texas Instruments and then mainly by IBM up through the end of 1998. Starting in 1999, National Semiconductor took over manufacturing of the Cyrix processors. More recently, National has been purchased by VIA Technologies.

Similar to Intel, Cyrix has begun to limit its selection of available CPUs to only the latest technology. Cyrix is currently focusing on the Pentium market with the M1 (6x86) and M2 (6x86MX) processors. The 6x86 has dual internal pipelines and a single, unified 16KB internal cache. It offers speculative and out-of-order instruction execution, much like the Intel Pentium Pro processor. The 6x86MX adds MMX technology to the CPU. The chip is Socket 7 compatible, but some require modified chipsets and new motherboard designs. See Table 3.5 earlier in this chapter, which shows the Cyrix processors.

The 6x86MX features 64KB of unified L1 cache and more than double the performance of the previous 6x86 CPUs. The 6x86MX is offered in clock speeds ranging from 180 to 266MHz, and similar to the 6x86, it is Socket 7 compatible. When running at speeds of 300MHz and higher, the 686MX was renamed the MII. Besides the higher speeds, all other functions are virtually identical. All Cyrix chips were manufactured by other companies such as IBM, which also markets the 6x86 chips under its own name. National began manufacturing Cyrix processors during 1998, but now that Cyrix is selling them off, the future is unclear.

Note that later versions of the 6x86MX chip have been renamed the MII to deliberately invoke comparisons with the Pentium II, instead of the regular Pentium processor. The MII chips are not redesigned; they are, in fact, the same 6x86MX chips as before, only running at higher clock rates. The first renamed 6x86MX chip is the MII 300, which actually runs at only 233MHz on a 66MHz Socket 7 motherboard. There is also an MII 333, which will run at a 250MHz clock speed on newer 100MHz Super7 motherboards.

Cyrix also has made an attempt at capturing even more of the low-end market than it already has by introducing a processor called the MediaGX. This is a low-performance cross between a 486 and a Pentium combined with a custom motherboard chipset in a two-chip package. These two chips contain everything necessary for a motherboard, except the Super I/O chip, and make very low-cost PCs possible.

P1 (086) First-Generation Processors

The first generation of processors represents the series of chips from Intel that were found in the first PCs. IBM, as the architect of the PC at the time, chose Intel processors and support chips to build the PC motherboard, setting a standard that would hold for many subsequent processor generations to come.

8088 and 8086 Processors

Intel introduced a revolutionary new processor called the 8086 back in June 1978. The 8086 was one of the first 16-bit processor chips on the market; at the time, virtually all other processors were 8-bit designs. The 8086 had 16-bit internal registers and could run a new class of software using 16-bit instructions. It also had a 16-bit external data path, so it could transfer data to memory 16 bits at a time.

The address bus was 20 bits wide, which enabled the 8086 to address a full 1MB (2^{20}) of memory. This was in stark contrast to most other chips of that time that had 8-bit internal registers, an 8-bit external data bus, and a 16-bit address bus allowing a maximum of only 64KB of RAM (2^{16}).

Unfortunately, most of the personal computer world at the time was using 8-bit processors, which ran 8-bit CP/M (Control Program for Microprocessors) operating systems and software. The board and circuit designs at the time were largely 8-bit, as well. Building a full 16-bit motherboard and memory system was costly, pricing such a computer out of the market.

The cost was high because the 8086 needed a 16-bit data bus rather than a less expensive 8-bit bus. Systems available at that time were 8-bit, and slow sales of the 8086 indicated to Intel that people weren't willing to pay for the extra performance of the full 16-bit design. In response, Intel introduced a kind of crippled version of the 8086, called the 8088. The 8088 essentially deleted 8 of the 16 bits on the data bus, making the 8088 an 8-bit chip as far as data input and output were concerned. However, because it retained the full 16-bit internal registers and the 20-bit address bus, the 8088 ran 16-bit software and was capable of addressing a full 1MB of RAM.

For these reasons, IBM selected the 8-bit 8088 chip for the original IBM PC. Years later, IBM was criticized for using the 8-bit 8088 instead of the 16-bit 8086. In retrospect, it was a very wise decision. IBM even covered up the physical design in its ads, which at the time indicated its new PC had a "high-speed 16-bit microprocessor." IBM could say that because the 8088 still ran the same powerful 16-bit software the 8086 ran, just a little more slowly. In fact, programmers universally thought of the 8088 as a 16-bit chip because there was virtually no way a program could distinguish an 8088 from an 8086. This enabled IBM to deliver a PC capable of running a new generation of 16-bit software, while retaining a much less expensive 8-bit design for the hardware. Because of this, the IBM PC was actually priced less at its introduction than the most popular PC of the time, the Apple II. For the trivia buffs out there, the IBM PC listed for $1,265 and included only 16KB of RAM, whereas a similarly configured Apple II cost $1,355.

Even though the 8088 was introduced in June 1979, the original IBM PC that used the processor did not appear until August 1981. Back then, a significant lag time often occurred between the introduction of a new processor and systems that incorporated it. That is unlike today, when new processors and systems using them often are released on the same day.

The 8088 in the IBM PC ran at 4.77MHz; the average instruction on the 8088 took 12 cycles to complete.

Computer users sometimes wonder why a 640KB conventional-memory barrier exists if the 8088 chip can address 1MB of memory. The conventional-memory barrier exists because IBM reserved 384KB of the upper portion of the 1,024KB (1MB) address space of the 8088 for use by adapter cards and system BIOS. The lower 640KB is the conventional memory in which DOS and software applications execute.

80186 and 80188 Processors

After Intel produced the 8086 and 8088 chips, it turned its sights toward producing a more powerful chip with an increased instruction set. The company's first efforts along this line—the 80186 and 80188—were unsuccessful. But incorporating system components into the CPU chip was an important idea for Intel because it led to faster, better chips, such as the 286.

The relationship between the 80186 and 80188 is the same as that of the 8086 and 8088; one is a slightly more advanced version of the other. Compared CPU to CPU, the 80186 is almost the same as the 8088 and has a full 16-bit design. The 80188 (like the 8088) is a hybrid chip that compromises the 16-bit design with an 8-bit external communications interface. The advantage of the 80186 and 80188 is that they combine on a single chip 15–20 of the 8086–8088 series system components—a fact that can greatly reduce the number of components in a computer design. The 80186 and 80188 chips were used for highly intelligent peripheral adapter cards of that age, such as network adapters.

8087 Coprocessor

Intel introduced the 8086 processor in 1976. The math coprocessor that was paired with the chip—the 8087—often was called the numeric data processor (NDP), the math coprocessor, or simply the math chip. The 8087 is designed to perform high-level math operations at many times the speed of the main processor. The primary advantage of using this chip is the increased execution speed in number-crunching programs, such as spreadsheet applications.

P2 (286) Second-Generation Processors

The second generation of PC processors allowed for a great leap in system speed and processing efficiency. With these chips we went from moving 8 bits of data around to moving 16 bits at a time. The following section details the second-generation PC processor, the 286.

286 Processors

The Intel 80286 (normally abbreviated as 286) processor did not suffer from the compatibility problems that damned the 80186 and 80188. The 286 chip, first introduced in 1981, is the CPU behind the original IBM AT. Other computer makers manufactured what came to be known as IBM clones, with many of these manufacturers calling their systems AT-compatible or AT-class computers.

When IBM developed the AT, it selected the 286 as the basis for the new system because the chip provided compatibility with the 8088 used in the PC and the XT. Therefore, software written for those chips should run on the 286. The 286 chip is many times faster than the 8088 used in the XT, and it offered a major performance boost to PCs used in businesses. The processing speed, or throughput, of the original AT (which ran at 6MHz) was five times greater than that of the PC running at 4.77MHz. The die for the 286 is shown in Figure 3.31.

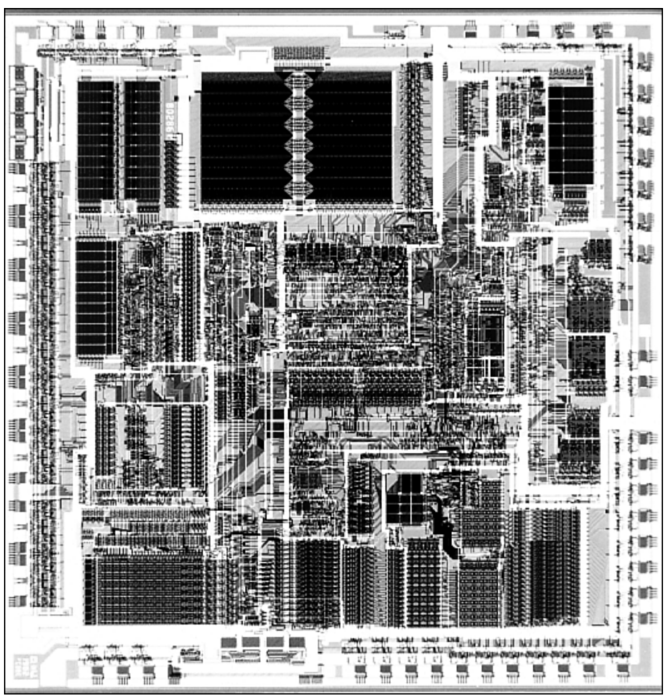

Figure 3.31 286 Processor die. *Photograph used by permission of Intel Corporation.*

286 systems are faster than their predecessors for several reasons. The main reason is that 286 processors are much more efficient in executing instructions. An average instruction takes 12 clock cycles on the 8086 or 8088, but takes an average of only 4.5 cycles on the 286 processor. Additionally, the 286 chip can handle up to 16 bits of data at a time through an external data bus twice the size of the 8088.

The 286 chip has two modes of operation: real mode and protected mode. The two modes are distinct enough to make the 286 resemble two chips in one. In real mode, a 286 acts essentially the same as an 8086 chip and is fully *object-code compatible* with the 8086 and 8088. (A processor with object-code compatibility can run programs written for another processor without modification and execute every system instruction in the same manner.)

In the protected mode of operation, the 286 was truly something new. In this mode, a program designed to take advantage of the chip's capabilities believes that it has access to 1GB of memory (including virtual memory). The 286 chip, however, can address only 16MB of hardware memory. A significant failing of the 286 chip is that it cannot switch from protected mode to real mode without a hardware reset (a warm reboot) of the system. (It can, however, switch from real mode to protected mode without a reset.) A major improvement of the 386 over the 286 is that software can switch the 386 from real mode to protected mode, and vice versa. See the section "Processor Modes," earlier in this chapter for more information.

Only a small amount of software that took advantage of the 286 chip was sold until Windows 3.0 offered standard mode for 286 compatibility; by that time, the hottest-selling chip was the 386. Still, the 286 was Intel's first attempt to produce a CPU chip that supported multitasking, in which multiple programs run at the same time. The 286 was designed so that if one program locked up or failed, the entire system didn't need a warm boot (reset) or cold boot (power off, then back on). Theoretically, what happened in one area of memory didn't affect other programs. Before multitasked programs could be "safe" from one another, however, the 286 chip (and subsequent chips) needed an operating system that worked cooperatively with the chip to provide such protection.

80287 Coprocessor

The 80287, internally, is the same math chip as the 8087, although the pins used to plug them into the motherboard are different. Both the 80287 and the 8087 operate as though they were identical.

In most systems, the 80286 internally divides the system clock by two to derive the processor clock. The 80287 internally divides the system-clock frequency by three. For this reason, most AT-type computers run the 80287 at one-third the system clock rate, which also is two-thirds the clock speed of the 80286. Because the 286 and 287 chips are asynchronous, the interface between the 286 and 287 chips is not as efficient as with the 8088 and 8087.

In summary, the 80287 and the 8087 chips perform about the same at equal clock rates. The original 80287 is not better than the 8087 in any real way—unlike the 80286, which is superior to the 8086 and 8088. In most AT systems, the performance gain that you realize by adding the coprocessor is much less substantial than the same type of upgrade for PC- or XT-type systems or for the 80386.

286 Processor Problems

After you remove a math coprocessor from an AT-type system, you must rerun your computer's Setup program. Some AT-compatible Setup programs do not properly unset the math coprocessor bit. If you receive a POST error message because the computer cannot find the math chip, you might have to unplug the battery from the system board temporarily. All Setup information will be lost, so be sure to write down the hard drive type, floppy drive type, and memory and video configurations before unplugging the battery. This information is critical in reconfiguring your computer correctly.

P3 (386) Third-Generation Processors

The third generation represents perhaps the most significant change in processors since the first PC. The big deal was the migration from processors that handled 16-bit operations to true 32-bit chips. The third-generation processors were so far ahead of their time, it took fully 10 years before 32-bit operating systems and software became mainstream, and by that time the third-generation chips had become a memory. The following section details the third-generation processors.

386 Processors

The Intel 80386 (normally abbreviated as 386) caused quite a stir in the PC industry because of the vastly improved performance it brought to the personal computer. Compared with 8088 and 286 systems, the 386 chip offered greater performance in almost all areas of operation.

The 386 is a full 32-bit processor optimized for high-speed operation and multitasking operating systems. Intel introduced the chip in 1985, but the 386 appeared in the first systems in late 1986 and early 1987. The Compaq Deskpro 386 and systems made by several other manufacturers introduced the chip; somewhat later, IBM used the chip in its PS/2 Model 80. The 386 chip rose in popularity for several years, which peaked around 1991. Obsolete 386 processor systems are mostly retired or scrapped, having been passed down the user chain. If they are in operating condition, they can be useful for running old DOS or Windows 3.x–based applications, which they can do quite nicely.

The 386 can execute the real-mode instructions of an 8086 or 8088, but in fewer clock cycles. The 386 was as efficient as the 286 in executing instructions—the average instruction took about 4.5 clock cycles. In raw performance, therefore, the 286 and 386 actually seemed to be at almost equal clock rates. Many 286 system manufacturers were touting their 16MHz and 20MHz 286 systems as being just as fast as 16MHz and 20MHz 386 systems, and they were right! The 386 offered greater performance in other ways, mainly because of additional software capability (modes) and a greatly enhanced memory management unit (MMU). The die for the 386 is shown in Figure 3.32.

The 386 can switch to and from protected mode under software control without a system reset—a capability that makes using protected mode more practical. In addition, the 386 has a new mode, called virtual real mode, which enables several real-mode sessions to run simultaneously under protected mode.

The protected mode of the 386 is fully compatible with the protected mode of the 286. The protected mode for both chips often is called their native mode of operation because these chips are designed for advanced operating systems such as OS/2 and Windows NT, which run only in protected mode. Intel extended the memory-addressing capabilities of 386 protected mode with a new MMU that provided advanced memory paging and program switching. These features were extensions of the 286 type of MMU, so the 386 remained fully compatible with the 286 at the system-code level.

The 386 chip's virtual real mode was new. In virtual real mode, the processor could run with hardware memory protection while simulating an 8086's real-mode operation. Multiple copies of DOS and other operating systems, therefore, could run simultaneously on this processor, each in a protected area of memory. If the programs in one segment crashed, the rest of the system was protected. Software commands could reboot the blown partition.

Numerous variations of the 386 chip exist, some of which are less powerful and some of which are less power hungry. The following sections cover the members of the 386-chip family and their differences.

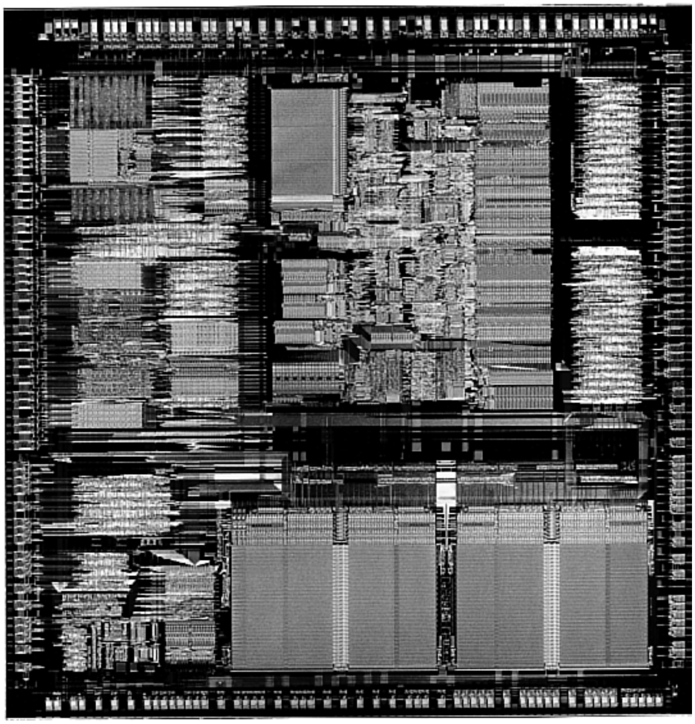

Figure 3.32 386 processor die. *Photograph used by permission of Intel Corporation.*

386DX Processors

The 386DX chip was the first of the 386 family members that Intel introduced. The 386 is a full 32-bit processor with 32-bit internal registers, a 32-bit internal data bus, and a 32-bit external data bus. The 386 contains 275,000 transistors in a very large scale integration (VLSI) circuit. The chip comes in a 132-pin package and draws approximately 400 milliamperes (ma), which is less power than even the 8086 requires. The 386 has a smaller power requirement because it is made of Complementary Metal-Oxide Semiconductor (CMOS) materials. The CMOS design enables devices to consume extremely low levels of power.

The Intel 386 chip was available in clock speeds ranging from 16MHz–33MHz; other manufacturers, primarily AMD and Cyrix, offered comparable versions with speeds up to 40MHz.

The 386DX can address 4GB of physical memory. Its built-in virtual memory manager enables software designed to take advantage of enormous amounts of memory to act as though a system has 64TB of memory. (A terabyte, or TB, is 1,099,511,627,776 bytes of memory, or about 1,000GB.)

386SX Processors

The 386SX was designed for systems designers looking for 386 capabilities at 286 system prices. Similar to the 286, the 386SX is restricted to only 16 bits when communicating with other system components, such as memory. Internally, however, the 386SX is identical to the DX chip; the 386SX has 32-bit internal registers and can therefore run 32-bit software. The 386SX uses a 24-bit memory-addressing scheme like that of the 286, rather than the full 32-bit memory address bus of the standard

386. The 386SX, therefore, can address a maximum 16MB of physical memory rather than the 4GB of physical memory the 386DX can address. Before it was discontinued, the 386SX was available in clock speeds ranging from 16MHz to 33MHz.

The 386SX signaled the end of the 286 because of the 386SX chip's superior MMU and the addition of the virtual real mode. Under a software manager such as Windows or OS/2, the 386SX can run numerous DOS programs at the same time. The capability to run 386-specific software is another important advantage of the 386SX over any 286 or older design. For example, Windows 3.1 runs nearly as well on a 386SX as it does on a 386DX.

386SL Processors

The 386SL is another variation on the 386 chip. This low-power CPU had the same capabilities as the 386SX, but it was designed for laptop systems in which low power consumption was necessary. The SL chips offered special power-management features that were important to systems that ran on batteries. The SL chip also offered several sleep modes to conserve power.

The chip included an extended architecture that contained a System Management Interrupt (SMI), which provided access to the power-management features. Also included in the SL chip was special support for LIM (Lotus Intel Microsoft) expanded memory functions and a cache controller. The cache controller was designed to control a 16KB–64KB external processor cache.

These extra functions account for the higher transistor count in the SL chips (855,000) compared with even the 386DX processor (275,000). The 386SL was available in 25MHz clock speed.

Intel offered a companion to the 386SL chip for laptops called the 82360SL I/O subsystem. The 82360SL provided many common peripheral functions, such as serial and parallel ports, a direct memory access (DMA) controller, an interrupt controller, and power-management logic for the 386SL processor. This chip subsystem worked with the processor to provide an ideal solution for the small size and low power-consumption requirements of portable and laptop systems.

80387 Coprocessor

Although the 80387 chips ran asynchronously, 386 systems were designed so that the math chip runs at the same clock speed as the main CPU. Unlike the 80287 coprocessor, which was merely an 8087 with different pins to plug into the AT motherboard, the 80387 coprocessor was a high-performance math chip specifically designed to work with the 386.

All 387 chips used a low power-consumption CMOS design. The 387 coprocessor had two basic designs: the 387DX coprocessor, which was designed to work with the 386DX processor, and the 387SX coprocessor, which was designed to work with the 386SX, SL, or SLC processor.

Intel originally offered several speeds for the 387DX coprocessor. But when the company designed the 33MHz version, a smaller mask was required to reduce the lengths of the signal pathways in the chip. This increased the performance of the chip by roughly 20%.

Note

Because Intel lagged in developing the 387 coprocessor, some early 386 systems were designed with a socket for a 287 coprocessor. Performance levels associated with that union, however, leave much to be desired.

Installing a 387DX is easy, but you must be careful to orient the chip in its socket properly; otherwise, the chip will be destroyed. The most common cause of burned pins on the 387DX is incorrect installation. In many systems, the 387DX was oriented differently from other large chips. Follow the manufacturer's installation instructions carefully to avoid damaging the 387DX; Intel's warranty does not cover chips that are installed incorrectly.

Several manufacturers developed their own versions of the Intel 387 coprocessors, some of which were touted as being faster than the original Intel chips. The general compatibility record of these chips was very good.

Weitek Coprocessors

In 1981, several Intel engineers formed the Weitek Corporation. Weitek developed math coprocessors for several systems, including those based on Motorola processor designs. Intel originally contracted Weitek to develop a math coprocessor for the Intel 386 CPU because Intel was behind in its own development of the 387 math coprocessor. The result was the Weitek 1167, a custom math coprocessor that uses a proprietary Weitek instruction set that is incompatible with the Intel 387.

To use the Weitek coprocessor, your system must have the required additional socket, which is different from the standard Intel coprocessor sockets.

80386 Bugs

Some early 16MHz Intel 386DX processors had a small bug that appeared as a software problem. The bug, which apparently was in the chip's 32-bit multiply routine, manifested itself only when true 32-bit code was run in a program such as OS/2 2.x, Unix/386, or Windows in enhanced mode. Some specialized 386 memory-management software systems also might invoke this subtle bug, but 16-bit operating systems (such as DOS and OS/2 1.x) probably will not.

The bug usually causes the system to lock up. Diagnosing this problem can be difficult because the problem generally is intermittent and software related. Running tests to find the bug is difficult; only Intel, with proper test equipment, can determine whether a chip has a bug. Some programs can diagnose the problem and identify a defective chip, but they cannot identify all defective chips. If a program indicates a bad chip, you certainly have a defective one; however, if the program passes the chip, you still might have a defective one.

Intel requested that its 386 customers return possibly defective chips for screening, but many vendors did not return them. Intel tested returned chips and replaced defective ones. The defective chips later were sold to bargain liquidators or systems houses that wanted chips that would not run 32-bit code. The defective chips were stamped with a 16-bit SW Only logo, indicating they were authorized to run only 16-bit software.

Chips that passed the test, and all subsequent chips produced as bug-free, were marked with a double-sigma code (SS). 386DX chips not marked with either of these designations have not been tested by Intel and might be defective.

This problem was discovered and corrected before Intel officially added DX to the part number. So, if you have a chip labeled 80386DX or 386DX, it does not have this problem.

Another problem with the 386DX can be stated more specifically. When 386-based versions of XENIX or other Unix implementations are run on a computer that contains a 387DX math coprocessor, the computer locks up under certain conditions. The problem does not occur in the DOS environment, however. For the lockup to occur, all the following conditions must be in effect:

- Demand page virtual memory must be active.
- A 387DX must be installed and in use.
- DMA must occur.
- The 386 must be in a wait state.

When all these conditions are true at the same instant, the 386DX ends up waiting for the 387DX and vice versa. Both processors will continue to wait for each other indefinitely. The problem is in certain versions of the 386DX, not in the 387DX math coprocessor.

Intel published this problem (Errata 21) immediately after it was discovered to inform its OEM customers. At that point, it became the responsibility of each manufacturer to implement a fix in its hardware or software product. Some manufacturers, such as Compaq and IBM, responded by modifying their motherboards to prevent these lockups from occurring.

The Errata 21 problem occurs only in the B-stepping version of the 386DX and not in the later D-stepping version. You can identify the D-stepping version of the 386DX by the letters DX in the part number (for example, 386DX-20). If DX is part of the chip's part number, the chip does not have this problem.

P4 (486) Fourth-Generation Processors

The third generation had been a large change from the previous generations of processors. With the fourth generation, more refinement than complete redesign was accomplished. Even so, Intel, AMD, and others managed to literally double processor performance with their fourth-generation processors. The following section defines the fourth-generation processors from Intel, AMD, and others.

486 Processors

In the race for more speed, the Intel 80486 (normally abbreviated as 486) was another major leap forward. The additional power available in the 486 fueled tremendous growth in the software industry. Tens of millions of copies of Windows, and millions of copies of OS/2, have been sold largely because the 486 finally made the GUI of Windows and OS/2 a realistic option for people who work on their computers every day.

Four main features make a given 486 processor roughly twice as fast as an equivalent MHz 386 chip. These features are

- *Reduced instruction-execution time.* A single instruction in the 486 takes an average of only two clock cycles to complete, compared with an average of more than four cycles on the 386. Clock-multiplied versions, such as the DX2 and DX4, further reduced this to about two cycles per instruction.
- *Internal (Level 1) cache.* The built-in cache has a hit ratio of 90%–95%, which describes how often zero-wait-state read operations occur. External caches can improve this ratio further.
- *Burst-mode memory cycles.* A standard 32-bit (4-byte) memory transfer takes two clock cycles. After a standard 32-bit transfer, more data up to the next 12 bytes (or three transfers) can be transferred with only one cycle used for each 32-bit (4-byte) transfer. Thus, up to 16 bytes of contiguous, sequential memory data can be transferred in as little as five cycles instead of eight cycles or more. This effect can be even greater when the transfers are only 8 bits or 16 bits each.

▶▶ See "Burst EDO," p. 417.

- *Built-in (synchronous) enhanced math coprocessor (some versions).* The math coprocessor runs synchronously with the main processor and executes math instructions in fewer cycles than previous designs did. On average, the math coprocessor built into the DX-series chips provides two to three times greater math performance than an external 387 chip.

The 486 chip is about twice as fast as the 386, so a 386DX-40 is about as fast as a 486SX-20. This made the 486 a much more desirable option, primarily because it could more easily be upgraded to a DX2 or DX4 processor at a later time. You can see why the arrival of the 486 rapidly killed off the 386 in the marketplace.

Before the 486, many people avoided GUIs because they didn't have time to sit around waiting for the hourglass, which indicates that the system is performing behind-the-scenes operations the user cannot interrupt. The 486 changed that situation. Many people believe the 486 CPU chip spawned the widespread acceptance of GUIs.

With the release of its faster Pentium CPU chip, Intel began to cut the price of the 486 line to entice the industry to shift over to the 486 as the mainstream system. Intel later did the same thing with its Pentium chips, spelling the end of the 486 line. The 486 is now offered by Intel only for use in embedded microprocessor applications, used primarily in expansion cards.

Most of the 486 chips were offered in a variety of maximum speed ratings, varying from 16MHz up to 120MHz. Additionally, 486 processors have slight differences in overall pin configurations. The DX, DX2, and SX processors have a virtually identical 168-pin configuration, whereas the OverDrive chips have either the standard 168-pin configuration or a specially modified 169-pin OverDrive (sometimes also called 487SX) configuration. If your motherboard has two sockets, the primary one likely supports the standard 168-pin configuration, and the secondary (OverDrive) socket supports the 169-pin OverDrive configuration. Most newer motherboards with a single ZIF socket support any of the 486 processors except the DX4. The DX4 is different because it requires 3.3v to operate instead of 5v, like most other chips up to that time.

A processor rated for a given speed always functions at any of the lower speeds. A 100MHz-rated 486DX4 chip, for example, runs at 75MHz if it is plugged into a 25MHz motherboard. Note that the DX2/OverDrive processors operate internally at two times the motherboard clock rate, whereas the DX4 processors operate at two, two-and-one-half, or three times the motherboard clock rate. Table 3.20 shows the various speed combinations that can result from using the DX2 or DX4 processors with different motherboard clock speeds.

Table 3.20 Intel DX2 and DX4 Operating Speeds Versus Motherboard Clock Speeds

Processor Speed	DX2 (2× mode) Speed	DX4 (2.5× mode) Speed	DX4 (3× mode) Speed	DX4
16MHz Motherboard	32MHz	32MHz	40MHz	48MHz
40MHz Motherboard	80MHz	80MHz	100MHz	120MHz
20MHz Motherboard	40MHz	40MHz	50MHz	60MHz
50MHz Motherboard	n/a	100MHz	n/a	n/a
25MHz Motherboard	50MHz	50MHz	63MHz	75MHz
33MHz Motherboard	66MHz	66MHz	83MHz	100MHz

The internal core speed of the DX4 processor is controlled by the CLKMUL (clock multiplier) signal at pin R-17 (Socket 1) or S-18 (Socket 2, 3, or 6). The CLKMUL input is sampled only during a reset of the CPU and defines the ratio of the internal clock to the external bus frequency CLK signal at pin C-3 (Socket 1) or D-4 (Socket 2, 3, or 6). If CLKMUL is sampled low, the internal core speed is two times the external bus frequency. If driven high or left floating (most motherboards would leave it floating), triple speed mode is selected. If the CLKMUL signal is connected to the BREQ (bus request) output signal at pin Q-15 (Socket 1) or R-16 (Socket 2, 3, or 6), the CPU internal core speed is two and a half times the CLK speed. To summarize, here is how the socket must be wired for each DX4 speed selection:

CPU Speed	CLKMUL (Sampled Only at CPU Reset)
2x	Low
2.5x	Connected to BREQ
3x	High or floating

You must determine how your particular motherboard is wired and whether it can be changed to alter the CPU core speed in relation to the CLK signal. In most cases, one or two jumpers will be on the board near the processor socket. The motherboard documentation should cover these settings if they can be changed.

One interesting capability here is to run the DX4-100 chip in a doubled mode with a 50MHz motherboard speed. This gives you a very fast memory bus, along with the same 100MHz processor speed, as if you were running the chip in a 33/100MHz tripled mode.

Note

One caveat is that if your motherboard has VL-Bus slots, they must be slowed down to 33MHz or 40MHz to operate properly.

Many VL-Bus motherboards can run the VL-Bus slots in a buffered mode, add wait states, or even selectively change the clock only for the VL-Bus slots to keep them compatible. In most cases, they don't run properly at 50MHz. Consult your motherboard—or even better, your chipset documentation—to see how your board is set up.

Caution

When upgrading an existing system, you should be sure that your socket supports the chip you are installing. This was especially true when putting a DX4 processor in an older system. In that scenario, you needed some type of adapter to regulate the voltage down to 3.3v. Putting the DX4 in a 5v socket destroys the chip! See the earlier section on processor sockets for more information.

The 486-processor family is designed for greater performance than previous processors because it integrates formerly external devices, such as cache controllers, cache memory, and math coprocessors. Also, 486 systems were the first designed for true processor upgradability. Most 486 systems can be upgraded by simple processor additions or swaps that can effectively double the speed of the system.

486DX Processors

The original Intel 486DX processor was introduced on April 10, 1989, and systems using this chip first appeared during 1990. The first chips had a maximum speed rating of 25MHz; later versions of the 486DX were available in 33MHz- and 50MHz-rated versions. The 486DX originally was available only in a 5v, 168-pin PGA version, but now is also available in 5v, 196-pin plastic quad flat pack (PQFP) and 3.3v, 208-pin small quad flat pack (SQFP). These latter form factors are available in SL enhanced versions, which are intended primarily for portable or laptop applications in which saving power is important.

Two main features separate the 486 processor from its predecessors:

- The 486DX integrates functions such as the math coprocessor, cache controller, and cache memory into the chip.
- The 486 also was designed with upgradability in mind; double-speed OverDrive were upgrades available for most systems.

The 486DX processor is fabricated with low-power CMOS technology. The chip has a 32-bit internal register size, a 32-bit external data bus, and a 32-bit address bus. These dimensions are equal to those of the 386DX processor. The internal register size is where the "32-bit" designation used in advertisements comes from. The 486DX chip contains 1.2 million transistors on a piece of silicon no larger than your thumbnail. This figure is more than four times the number of components on 386 processors and should give you a good indication of the 486 chip's relative power. The die for the 486 is shown in Figure 3.33.

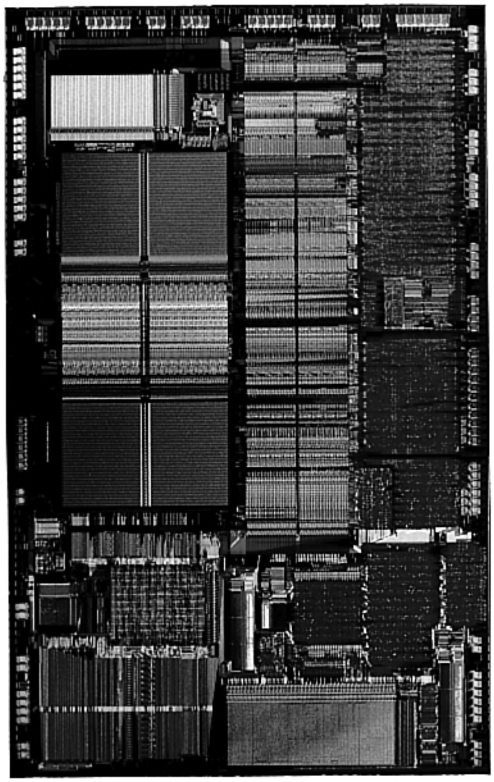

Figure 3.33 486 processor die. *Photograph used by permission of Intel Corporation.*

The standard 486DX contains a processing unit, floating-point unit (math coprocessor), memory-management unit, and cache controller with 8KB of internal-cache RAM. Due to the internal cache and a more efficient internal processing unit, the 486 family of processors can execute individual instructions in an average of only 2 processor cycles. Compare this figure with the 286 and 386 families, both of which execute an average 4.5 cycles per instruction. Compare it also with the original 8086 and 8088 processors, which execute an average 12 cycles per instruction. At a given clock rate (MHz), therefore, a 486 processor is roughly twice as efficient as a 386 processor; a 16MHz 486SX is roughly equal to a 33MHz 386DX system; and a 20MHz 486SX is equal to a 40MHz 386DX system. Any of the faster 486s are way beyond the 386 in performance.

The 486 is fully instruction-set–compatible with previous Intel processors, such as the 386, but offers several additional instructions (most of which have to do with controlling the internal cache).

Similar to the 386DX, the 486 can address 4GB of physical memory and manage as much as 64TB of virtual memory. The 486 fully supports the three operating modes introduced in the 386: real mode, protected mode, and virtual real mode:

- *In real mode*, the 486 (similar to the 386) runs unmodified 8086-type software.
- *In protected mode*, the 486 (similar to the 386) offers sophisticated memory paging and program switching.

- *In virtual real mode*, the 486 (similar to the 386) can run multiple copies of DOS or other operating systems while simulating an 8086's real-mode operation. Under an operating system such as Windows or OS/2, therefore, both 16-bit and 32-bit programs can run simultaneously on this processor with hardware memory protection. If one program crashes, the rest of the system is protected, and you can reboot the blown portion through various means, depending on the operating software.

The 486DX series has a built-in math coprocessor that sometimes is called an MCP (math coprocessor) or FPU. This series is unlike previous Intel CPU chips, which required you to add a math coprocessor if you needed faster calculations for complex mathematics. The FPU in the 486DX series is 100% software-compatible with the external 387 math coprocessor used with the 386, but it delivers more than twice the performance. It runs in synchronization with the main processor and executes most instructions in half as many cycles as the 386.

486SL

The 486SL was a short-lived, standalone chip. The SL enhancements and features became available in virtually all the 486 processors (SX, DX, and DX2) in what are called SL enhanced versions. SL enhancement refers to a special design that incorporates special power-saving features.

The SL enhanced chips originally were designed to be installed in laptop or notebook systems that run on batteries, but they found their way into desktop systems, as well. The SL enhanced chips featured special power-management techniques, such as sleep mode and clock throttling, to reduce power consumption when necessary. These chips were available in 3.3v versions, as well.

Intel designed a power-management architecture called system management mode. This mode of operation is totally isolated and independent from other CPU hardware and software. SMM provides hardware resources such as timers, registers, and other I/O logic that can control and power down mobile-computer components without interfering with any of the other system resources. SMM executes in a dedicated memory space called system management memory, which is not visible and does not interfere with operating system and application software. SMM has an interrupt called system management interrupt (SMI), which services power-management events and is independent from—and higher priority than—any of the other interrupts.

SMM provides power management with flexibility and security that were not available previously. For example, an SMI occurs when an application program tries to access a peripheral device that is powered down for battery savings, which powers up the peripheral device and reexecutes the I/O instruction automatically.

Intel also designed a feature called Suspend/Resume in the SL processor. The system manufacturer can use this feature to provide the portable computer user with instant on-and-off capability. An SL system typically can resume (instant on) in one second from the suspend state (instant off) to exactly where it left off. You do not need to reboot, load the operating system, load the application program, and then load the application data. Simply push the Suspend/Resume button and the system is ready to go.

The SL CPU was designed to consume almost no power in the suspend state. This feature means that the system can stay in the suspend state possibly for weeks and yet start up instantly right where it left off. An SL system can keep working data in normal RAM memory safe for a long time while it is in the suspend state, but saving to a disk still is prudent.

486SX

The 486SX, introduced in April 1991, was designed to be sold as a lower-cost version of the 486. The 486SX is virtually identical to the full DX processor, but the chip does not incorporate the FPU or math coprocessor portion.

As you read earlier in this chapter, the 386SX was a scaled-down (some people would say crippled) 16-bit version of the full-blown 32-bit 386DX. The 386SX even had a completely different pinout and was not interchangeable with the more powerful DX version. The 486SX, however, is a different story. The 486SX is, in fact, a full-blown 32-bit 486 processor that is basically pin compatible with the DX. A few pin functions are different or rearranged, but each pin fits into the same socket.

The 486SX chip is more a marketing quirk than new technology. Early versions of the 486SX chip actually were DX chips that showed defects in the math-coprocessor section. Instead of being scrapped, the chips were packaged with the FPU section disabled and sold as SX chips. This arrangement lasted for only a short time; thereafter, SX chips got their own mask, which is different from the DX mask. (A *mask* is the photographic blueprint of the processor and is used to etch the intricate signal pathways into a silicon chip.) The transistor count dropped to 1.185 million (from 1.2 million) to reflect this new mask.

The 486SX chip is twice as fast as a 386DX with the same clock speed. Intel marketed the 486SX as being the ideal chip for new computer buyers because fewer entry-level programs of that day used math-coprocessor functions.

The 486SX was available in 16MHz-, 20MHz-, 25MHz-, and 33MHz-rated speeds, an a 486 SX/2 was also available that ran at up to 50MHz or 66MHz. The 486SX typically comes in a 168-pin version, although other surface-mount versions are available in SL-enhanced models.

Despite what Intel's marketing and sales information implies, no technical provision exists for adding a separate math coprocessor to a 486SX system; neither was a separate math coprocessor chip ever available to plug in. Instead, Intel wanted you to add a new 486 processor with a built-in math unit and disable the SX CPU that already was on the motherboard. If this situation sounds confusing, read on because this topic brings you to the most important aspect of 486 design: upgradability.

487SX

The 487SX math coprocessor, as Intel calls it, really is a complete 25MHz 486DX CPU with an extra pin added and some other pins rearranged. When the 487SX is installed in the extra socket provided in a 486SX CPU-based system, the 487SX turns off the existing 486SX via a new signal on one of the pins. The extra key pin actually carries no signal itself and exists only to prevent improper orientation when the chip is installed in a socket.

The 487SX takes over all CPU functions from the 486SX and also provides math coprocessor functionality in the system. At first glance, this setup seems rather strange and wasteful, so perhaps further explanation is in order. Fortunately, the 487SX turned out to be a stopgap measure while Intel prepared its real surprise: the OverDrive processor. The DX2/OverDrive speed-doubling chips, which are designed for the 487SX 169-pin socket, have the same pinout as the 487SX. These upgrade chips are installed in exactly the same way as the 487SX; therefore, any system that supports the 487SX also supports the DX2/OverDrive chips.

Although in most cases you can upgrade a system by removing the 486SX CPU and replacing it with a 487SX (or even a DX or DX2/OverDrive), Intel originally discouraged this procedure. Instead, Intel recommended that PC manufacturers include a dedicated upgrade (OverDrive) socket in their systems because several risks were involved in removing the original CPU from a standard socket. (The following section elaborates on those risks.) Now Intel recommends—or even insists on—the use of a single processor socket of a ZIF design, which makes upgrading an easy task physically.

◀◀ See "Zero Insertion Force Sockets," p. 95.

Very few early 486 systems had a socket for the Weitek 4167 coprocessor chip for 486 systems that existed in November 1989.

DX2/OverDrive and DX4 Processors

On March 3, 1992, Intel introduced the DX2 speed-doubling processors. On May 26, 1992, Intel announced that the DX2 processors also would be available in a retail version called OverDrive. Originally, the OverDrive versions of the DX2 were available only in 169-pin versions, which meant that they could be used only with 486SX systems that had sockets configured to support the rearranged pin configuration.

On September 14, 1992, Intel introduced 168-pin OverDrive versions for upgrading 486DX systems. These processors could be added to existing 486 (SX or DX) systems as an upgrade, even if those systems did not support the 169-pin configuration. When you use this processor as an upgrade, you install the new chip in your system, which subsequently runs twice as fast.

The DX2/OverDrive processors run internally at twice the clock rate of the host system. If the motherboard clock is 25MHz, for example, the DX2/OverDrive chip runs internally at 50MHz; likewise, if the motherboard is a 33MHz design, the DX2/OverDrive runs at 66MHz. The DX2/OverDrive speed doubling has no effect on the rest of the system; all components on the motherboard run the same as they do with a standard 486 processor. Therefore, you do not have to change other components (such as memory) to accommodate the double-speed chip. The DX2/OverDrive chips have been available in several speeds. Three speed-rated versions have been offered:

- 40MHz DX2/OverDrive for 16MHz or 20MHz systems
- 50MHz DX2/OverDrive for 25MHz systems
- 66MHz DX2/OverDrive for 33MHz systems

Notice that these ratings indicate the maximum speed at which the chip is capable of running. You could use a 66MHz-rated chip in place of the 50MHz- or 40MHz-rated parts with no problem, although the chip will run only at the slower speeds. The actual speed of the chip is double the motherboard clock frequency. When the 40MHz DX2/OverDrive chip is installed in a 16MHz 486SX system, for example, the chip functions only at 32MHz—exactly double the motherboard speed. Intel originally stated that no 100MHz DX2/OverDrive chip would be available for 50MHz systems—which technically has not been true because the DX4 could be set to run in a clock-doubled mode and used in a 50MHz motherboard (see the discussion of the DX4 processor in this section).

The only part of the DX2 chip that doesn't run at double speed is the bus interface unit, a region of the chip that handles I/O between the CPU and the outside world. By translating between the differing internal and external clock speeds, the bus interface unit makes speed doubling transparent to the rest of the system. The DX2 appears to the rest of the system to be a regular 486DX chip, but one that seems to execute instructions twice as fast.

DX2/OverDrive chips are based on the 0.8-micron circuit technology that was first used in the 50MHz 486DX. The DX2 contains 1.1 million transistors in a three-layer form. The internal 8KB cache, integer, and floating-point units all run at double speed. External communication with the PC runs at normal speed to maintain compatibility.

Besides upgrading existing systems, one of the best parts of the DX2 concept was the fact that system designers could introduce very fast systems by using cheaper motherboard designs, rather than the more costly designs that would support a straight high-speed clock. Therefore, a 50MHz 486DX2 system was much less expensive than a straight 50MHz 486DX system. The system board in a 486DX-50 system operates at a true 50MHz. The 486DX2 CPU in a 486DX2-50 system operates internally at 50MHz, but the motherboard operates at only 25MHz.

You might be thinking that a true 50MHz DX processor–based system still would be faster than a speed-doubled 25MHz system, and this generally is true. But, the differences in speed actually are very slight—a real testament to the integration of the 486 processor and especially to the cache design.

When the processor has to go to system memory for data or instructions, for example, it must do so at the slower motherboard operating frequency (such as 25MHz). Because the 8KB internal cache of the 486DX2 has a hit rate of 90%–95%, however, the CPU must access system memory only 5%–10% of the time for memory reads. Therefore, the performance of the DX2 system can come very close to that of a true 50MHz DX system and cost much less. Even though the motherboard runs at only 33.33MHz, a system with a DX2 66MHz processor ends up being faster than a true 50MHz DX system, especially if the DX2 system has a good L2 cache.

Many 486 motherboard designs also include a secondary cache that is external to the cache integrated into the 486 chip. This external cache allows for much faster access when the 486 chip calls for external-memory access. The size of this external cache can vary anywhere from 16KB to 512KB or more. When you add a DX2 processor, an external cache is even more important for achieving the greatest performance gain. This cache greatly reduces the wait states the processor must add when writing to system memory or when a read causes an internal cache miss. For this reason, some systems perform better with the DX2/OverDrive processors than others, usually depending on the size and efficiency of the external-memory cache system on the motherboard. Systems that have no external cache still enjoy a near-doubling of CPU performance, but operations that involve a great deal of memory access are slower.

This brings us to the DX4 processor. Although the standard DX4 technically was not sold as a retail part, it could be purchased from several vendors, along with the 3.3v voltage adapter needed to install the chip in a 5v socket. These adapters have jumpers that enable you to select the DX4 clock multiplier and set it to 2x, 2.5x, or 3x mode. In a 50MHz DX system, you could install a DX4/voltage-regulator combination set in 2x mode for a motherboard speed of 50MHz and a processor speed of 100MHz! Although you might not be able to take advantage of certain VL-Bus adapter cards, you will have one of the fastest 486-class PCs available.

Intel also sold a special DX4 OverDrive processor that included a built-in voltage regulator and heatsink that are specifically designed for the retail market. The DX4 OverDrive chip is essentially the same as the standard 3.3v DX4 with the main exception that it runs on 5v because it includes an on-chip regulator. Also, the DX4 OverDrive chip runs only in the tripled speed mode, and not the 2x or 2.5x modes of the standard DX4 processor.

Note

As of this writing, Intel has discontinued all 486 and DX2/DX4/OverDrive processors, including the so-called Pentium OverDrive processor.

Pentium OverDrive for 486SX2 and DX2 Systems

The Pentium OverDrive Processor became available in 1995. An OverDrive chip for 486DX4 systems had been planned, but poor marketplace performance of the SX2/DX2 chip resulted in it never seeing the light of day. One thing to keep in mind about the 486 Pentium OverDrive chip is that although it is intended primarily for SX2 and DX2 systems, it should work in any upgradable 486SX or DX system that has a Socket 2 or Socket 3. If in doubt, check Intel's online upgrade guide for compatibility.

The Pentium OverDrive processor is designed for systems that have a processor socket that follows the Intel Socket 2 specification. This processor also works in systems that have a Socket 3 design, although you should ensure that the voltage is set for 5v rather than 3.3v. The Pentium OverDrive chip includes a 32KB internal L1 cache and the same superscalar (multiple instruction path) architecture of the real Pentium chip. Besides a 32-bit Pentium core, these processors feature increased clock-speed operation due to internal clock multiplication and incorporate an internal write-back cache (standard with the Pentium). If the motherboard supports the write-back cache function, increased performance is realized. Unfortunately, most motherboards, especially older ones with the Socket 2 design, support only write-through cache.

Most tests of these OverDrive chips show them to be only slightly ahead of the DX4-100 and behind the DX4-120 and true Pentium 60, 66, or 75. Unfortunately, these are the only solutions still offered by Intel for upgrading the 486. Based on the relative affordability of low-end "real" Pentiums (in their day), it was hard not to justify making the step up to a Pentium system. At the time, I did not recommend the 486 Pentium OverDrive chips as a viable solution for the future.

AMD 486 (5x86)

AMD makes a line of 486-compatible chips that install into standard 486 motherboards. In fact, AMD makes the fastest 486 processor available, which it calls the Am5x86(TM)-P75. The name is a little misleading because the 5x86 part makes some people think that this is a fifth-generation Pentium-type processor. In reality, it is a fast clock-multiplied (4x clock) 486 that runs at four times the speed of the 33MHz 486 motherboard you plug it into.

The 5x85 offers high-performance features such as a unified 16KB write-back cache and 133MHz core clock speed; it is approximately comparable to a Pentium 75, which is why it is denoted with a P-75 in the part number. It is the ideal choice for cost-effective 486 upgrades, where changing the motherboard is difficult or impossible.

Not all motherboards support the 5x86. The best way to verify that your motherboard supports the chip is by checking with the documentation that came with the board. Look for keywords such as "Am5X86," "AMD-X5," "clock-quadrupled," "133MHz," or other similar wording. Another good way to determine whether your motherboard supports the AMD 5x86 is to look for it in the listed models on AMD's Web site.

There are a few things to note when installing a 5x86 processor into a 486 motherboard:

- *The operating voltage for the 5x86 is 3.45v +/- 0.15v.* Not all motherboards have this setting, but most that incorporate a Socket 3 design should. If your 486 motherboard is a Socket 1 or 2 design, you cannot use the 5x86 processor directly. The 3.45 volt processor will not operate in a 5-volt socket and can be damaged. To convert a 5-volt motherboard to 3.45 volts, processors with adapters can be purchased from several vendors, including Kingston and Evergreen. Both sell the 5x86 complete with a voltage regulator adapter attached in an easy-to-install package. These versions are ideal for older 486 motherboards that don't have a Socket 3 design.
- *It is generally better to purchase a new motherboard with Socket 3 than to buy one of these adapters.* However, 486 motherboards are hard to find these days, and your old board might be in a proprietary form factor for which finding a replacement is impossible. Buying a new motherboard is also better than using an adapter because the older BIOS might not understand the requirements of the processor as far as speed is concerned. BIOS updates often are required with older boards.
- *Most Socket 3 motherboards have jumpers, enabling you to set the voltage manually.* Some boards don't have jumpers, but have voltage autodetect instead. These systems check the VOLDET pin (pin S4) on the microprocessor when the system is powered on.
- *The VOLDET pin is tied to ground (Vss) internally to the microprocessor.* If you cannot find any jumpers for setting voltage, you can check the motherboard as follows: Switch the PC off, remove the microprocessor, connect pin S4 to a Vss pin on the ZIF socket, power on, and check any Vcc pin with a voltmeter. This should read 3.45 (± 0.15) volts. See the previous section on CPU sockets for the pinout.
- *The 5x86 requires a 33MHz motherboard speed, so be sure the board is set to that frequency.* The 5x86 operates at an internal speed of 133MHz. Therefore, the jumpers must be set for "clock-quadrupled" or "4x clock" mode. By setting the jumpers correctly on the motherboard, the CLKMUL pin (pin R17) on the processor will be connected to ground (Vss). If there is no 4x clock setting, the standard DX2 2x clock setting should work.

- *Some motherboards have jumpers that configure the internal cache in either write-back (WB) or write-through (WT) mode.* They do this by pulling the WB/WT pin (pin B13) on the microprocessor to logic High (Vcc) for WB or to ground (Vss) for WT. For best performance, configure your system in WB mode; however, reset the cache to WT mode if problems running applications occur or the floppy drive doesn't work right (DMA conflicts).
- *The 5x86 runs hot, so a heatsink is required.* It normally must have a fan.

In addition to the 5x86, the AMD-enhanced 486 product line includes 80MHz; 100MHz; and 1,20MHz CPUs. These are the A80486DX2-80SV8B (40MHz×2), A80486DX4-100SV8B (33MHz×3), and A80486DX4-120SV8B (40MHz×3).

Cyrix/TI 486

The Cyrix 486DX2/DX4 processors were available in 100MHz, 80MHz, 75MHz, 66MHz, and 50MHz versions. Similar to the AMD 486 chips, the Cyrix versions are fully compatible with Intel's 486 processors and work in most 486 motherboards.

The Cx486DX2/DX4 incorporates an 8KB write-back cache, an integrated floating-point unit, advanced power management, and SMM, and was available in 3.3v versions.

Note

TI originally made all the Cyrix-designed 486 processors, and under the agreement it also sold them under the TI name. They are essentially the same as the Cyrix chips.

P5 (586) Fifth-Generation Processors

After the fourth-generation chips such as the 486, Intel and other chip manufacturers went back to the drawing board to come up with new architectures and features that they incorporated into what they called fifth-generation chips. This section defines the fifth-generation processors from Intel, AMD, and others.

Pentium Processors

On October 19, 1992, Intel announced that the fifth generation of its compatible microprocessor line (codenamed P5) would be named the Pentium processor rather than the 586, as everybody had assumed. Calling the new chip the 586 would have been natural, but Intel discovered that it could not trademark a number designation, and the company wanted to prevent other manufacturers from using the same name for any clone chips they might develop. The actual Pentium chip shipped on March 22, 1993. Systems that use these chips were only a few months behind.

The Pentium is fully compatible with previous Intel processors, but it differs from them in many ways. At least one of these differences is revolutionary: The Pentium features twin data pipelines, which enable it to execute two instructions at the same time. The 486 and all preceding chips can perform only a single instruction at a time. Intel calls the capability to execute two instructions at the same time superscalar technology. This technology provides additional performance compared with the 486.

The standard 486 chip can execute a single instruction in an average of two clock cycles—cut to an average of one clock cycle with the advent of internal clock multiplication used in the DX2 and DX4 processors. With superscalar technology, the Pentium can execute many instructions at a rate of two instructions per cycle. Superscalar architecture usually is associated with high-output RISC chips. The Pentium is one of the first CISC chips to be considered superscalar. The Pentium is almost like having two 486 chips under the hood. Table 3.21 shows the Pentium processor specifications.

Table 3.21 Pentium Processor Specifications

Introduced	March 22, 1993 (first generation); March 7, 1994 (second generation)
Maximum rated speeds	60, 66, 75, 90, 100, 120, 133, 150, 166, 200MHz (second generation)
CPU clock multiplier	1x (first generation), 1.5x–3x (second generation)
Register size	32-bit
External data bus	64-bit
Memory address bus	32-bit
Maximum memory	4GB
Integral-cache size	8KB code, 8KB data
Integral-cache type	Two-way set associative, write-back data
Burst-mode transfers	Yes
Number of transistors	3.1 million
Circuit size	0.8 micron (60/66MHz), 0.6 micron (75MHz–100MHz), 0.35 micron (120MHz and up)
External package	273-pin PGA, 296-pin SPGA, tape carrier
Math coprocessor	Built-in FPU
Power management	SMM, enhanced in second generation
Operating voltage	5v (first generation); 3.465v, 3.3v, 3.1v, 2.9v (second generation)

PGA = Pin grid array

SPGA = Staggered pin grid array

The two instruction pipelines within the chip are called the u- and v-pipes. The *u-pipe*, which is the primary pipe, can execute all integer and floating-point instructions. The *v-pipe* is a secondary pipe that can execute only simple integer instructions and certain floating-point instructions. The process of operating on two instructions simultaneously in the different pipes is called *pairing*. Not all sequentially executing instructions can be paired, and when pairing is not possible, only the u-pipe is used. To optimize the Pentium's efficiency, you can recompile software to enable more instructions to be paired.

The Pentium processor has a branch target buffer (BTB), which employs a technique called branch prediction. It minimizes stalls in one or more of the pipes caused by delays in fetching instructions that branch to nonlinear memory locations. The BTB attempts to predict whether a program branch will be taken and then fetches the appropriate instructions. The use of branch prediction enables the Pentium to keep both pipelines operating at full speed. Figure 3.34 shows the internal architecture of the Pentium processor.

The Pentium has a 32-bit address bus width, giving it the same 4GB memory-addressing capabilities as the 386DX and 486 processors. But the Pentium expands the data bus to 64 bits, which means it can move twice as much data into or out of the CPU, compared with a 486 of the same clock speed. The 64-bit data bus requires that system memory be accessed 64 bits wide, so each bank of memory is 64 bits.

On most motherboards, memory is installed via SIMMs or DIMMs. SIMMs are available in 8-bit–wide and 32-bit–wide versions, whereas DIMMs are 64 bits wide. In addition, versions are available with additional bits for parity or error correcting code (ECC) data. Most Pentium systems use the 32-bit–wide SIMMs—two of these SIMMs per bank of memory. Most Pentium motherboards have at least four of these 32-bit SIMM sockets, providing for a total of two banks of memory. Later Pentium systems and most Pentium II systems today use DIMMs, which are 64 bits wide—just like the processor's external data bus, so only one DIMM is used per bank. This makes installing or upgrading memory much easier because DIMMs can go in one at a time and don't have to be matched up in pairs.

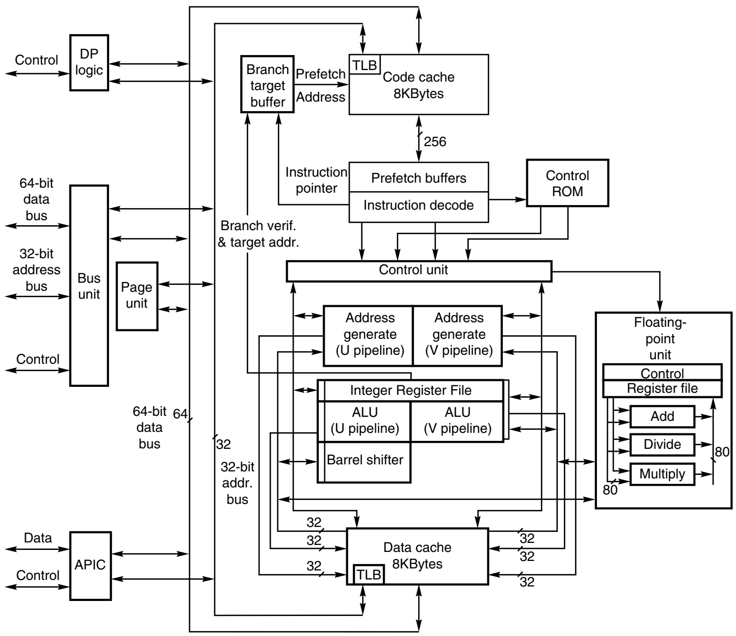

Figure 3.34 Pentium processor internal architecture.

▶▶ See "SIMMs, DIMMs, and RIMMs," p. 421, and "Memory Banks," p. 438.

Even though the Pentium has a 64-bit data bus that transfers information 64 bits at a time into and out of the processor, the Pentium has only 32-bit internal registers. As instructions are being processed internally, they are broken down into 32-bit instructions and data elements and processed in much the same way as in the 486. Some people thought that Intel was misleading them by calling the Pentium a 64-bit processor, but 64-bit transfers do indeed take place. Internally, however, the Pentium has 32-bit registers that are fully compatible with the 486.

The Pentium has two separate internal 8KB caches, compared with a single 8KB or 16KB cache in the 486. The cache-controller circuitry and the cache memory are embedded in the CPU chip. The cache mirrors the information in normal RAM by keeping a copy of the data and code from different memory locations. The Pentium cache also can hold information to be written to memory when the load on the CPU and other system components is less. (The 486 makes all memory writes immediately.)

The separate code and data caches are organized in a two-way set associative fashion, with each set split into lines of 32 bytes each. Each cache has a dedicated translation lookaside buffer (TLB) that translates linear addresses to physical addresses. You can configure the data cache as write-back or write-through on a line-by-line basis. When you use the write-back capability, the cache can store write operations and reads, further improving performance over read-only write-through mode. Using write-back mode results in less activity between the CPU and system memory—an important improvement because CPU access to system memory is a bottleneck on fast systems. The code cache is an inherently write-protected cache because it contains only execution instructions and not data, which is updated. Because burst cycles are used, the cache data can be read or written very quickly.

Systems based on the Pentium can benefit greatly from secondary processor caches (L2), which usually consist of up to 512KB or more of extremely fast (15ns or less) SRAM chips. When the CPU fetches data that is not already available in its internal processor (L1) cache, wait states slow the CPU. If the data already is in the secondary processor cache, however, the CPU can go ahead with its work without pausing for wait states.

The Pentium uses a Bipolar Complementary Metal-Oxide Semiconductor (BiCMOS) process and superscalar architecture to achieve the high level of performance expected from the chip. BiCMOS adds about 10% to the complexity of the chip design, but adds about 30%–35% better performance without a size or power penalty.

All Pentium processors are SL enhanced—they incorporate the SMM to provide full control of power-management features, which helps reduce power consumption. The second-generation Pentium processors (75MHz and faster) incorporate a more advanced form of SMM that includes processor clock control. This enables you to throttle the processor up or down to control power use. You can even stop the clock with these more advanced Pentium processors, putting the processor in a state of suspension that requires very little power. The second-generation Pentium processors run on 3.3v power (instead of 5v), reducing power requirements and heat generation even further.

Many current motherboards supply either 3.465v or 3.3v. The 3.465v setting is called VRE (voltage reduced extended) by Intel and is required by some versions of the Pentium, particularly some of the 100MHz versions. The standard 3.3v setting is called STD (standard), which most of the second-generation Pentiums use. STD voltage means anything in a range from 3.135v to 3.465v with 3.3v nominal. Additionally, a special 3.3v setting called VR (voltage reduced) reduces the range from 3.300v to 3.465v with 3.38v nominal. Some of the processors require this narrower specification, which most motherboards provide. Here is a summary:

Voltage Specification	Nominal	Tolerance	Minimum	Maximum
STD (standard)	3.30v	±0.165	3.135v	3.465v
VR (voltage reduced)	3.38v	±0.083	3.300v	3.465v
VRE (VR extended)	3.50v	±0.100	3.400v	3.600v

For even lower power consumption, Intel introduced special Pentium processors with voltage reduction technology in the 75 to 266MHz family; the processors are intended for mobile computer applications. They do not use a conventional chip package and are instead mounted using a new format called tape carrier packaging (TCP). The tape carrier packaging does not encase the chip in ceramic or plastic as with a conventional chip package, but instead covers the actual processor die directly with a thin, protective plastic coating. The entire processor is less than 1mm thick, or about half the thickness of a dime, and weighs less than 1 gram. They are sold to system manufacturers in a roll that looks very much like a filmstrip. The TCP processor is directly affixed (soldered) to the motherboard by a special machine, resulting in a smaller package, lower height, better thermal transfer, and lower power consumption. Special solder plugs on the circuit board located directly under the processor draw heat away and provide better cooling in the tight confines of a typical notebook or laptop system—no cooling fans are required. For more information on mobile processors and systems, see Chapter 22, "Portable PCs."

The Pentium, like the 486, contains an internal math coprocessor or FPU. The FPU in the Pentium has been rewritten and performs significantly better than the FPU in the 486, yet it is fully compatible with the 486 and 387 math coprocessors. The Pentium FPU is estimated to be two to as much as ten times faster than the FPU in the 486. In addition, the two standard instruction pipelines in the Pentium provide two units to handle standard integer math. (The math coprocessor handles only more complex calculations.) Other processors, such as the 486, have only a single-standard execution pipe and one integer math unit. Interestingly, the Pentium FPU contains a flaw that received widespread publicity. See the discussion in the section "Pentium Defects," later in this chapter.

First-Generation Pentium Processor

The Pentium has been offered in three basic designs, each with several versions. The first-generation design, which is no longer available, came in 60MHz and 66MHz processor speeds. This design used a 273-pin PGA form factor and ran on 5v power. In this design, the processor ran at the same speed as the motherboard—in other words, a 1x clock was used.

The first-generation Pentium was created through an 0.8- micron BiCMOS process. Unfortunately, this process, combined with the 3.1 million transistor count, resulted in a die that was overly large and complicated to manufacture. As a result, reduced yields kept the chip in short supply; Intel could not make them fast enough. The 0.8-micron process was criticized by other manufacturers, including Motorola and IBM, which had been using 0.6-micron technology for their most advanced chips. The huge die and 5v operating voltage caused the 66MHz versions to consume up to an incredible 3.2 amps or 16 watts of power, resulting in a tremendous amount of heat and problems in some systems that did not employ conservative design techniques. Fortunately, adding a fan to the processor solved most cooling problems, as long as the fan kept running.

Much of the criticism leveled at Intel for the first-generation Pentium was justified. Some people realized that the first-generation design was just that; they knew that new Pentium versions, made in a more advanced manufacturing process, were coming. Many of those people advised against purchasing any Pentium system until the second-generation version became available.

Tip

A cardinal rule of computing is never buy the first generation of any processor. Although you can wait forever because something better always will be on the horizon, a little waiting is worthwhile in some cases.

Those who purchased first-generation Pentiums still had a way out, however. As with previous 486 systems, Intel released OverDrive upgrade chips that effectively doubled the processor speed of the Pentium 60 or 66. These are a single-chip upgrade, meaning they replace the existing CPU. Because subsequent Pentiums are incompatible with the Pentium 60/66 Socket 4 arrangement, these OverDrive chips were the only way to upgrade an existing first-generation Pentium without replacing the motherboard.

Generally, it was better to consider a complete motherboard replacement, which would accept a newer design processor that would potentially be many times faster, than to upgrade using just an OverDrive processor, that might only be twice as fast.

Second-Generation Pentium Processor

Intel announced the second-generation Pentium on March 7, 1994. This new processor was introduced in 90MHz and 100MHz versions, with a 75MHz version not far behind. Eventually, 120MHz, 133MHz, 150MHz, 166MHz, and 200MHz versions were also introduced. The second-generation Pentium uses 0.6-micron (75/90/100MHz) BiCMOS technology to shrink the die and reduce power consumption. The newer, faster 120MHz (and higher) second-generation versions incorporate an even smaller die built on a 0.35-micron BiCMOS process. These smaller dies are not changed from the 0.6-micron versions; they are basically a photographic reduction of the P54C die. The die for the Pentium is shown in Figure 3.35. Additionally, these new processors run on 3.3v power. The 100MHz version consumes a maximum of 3.25 amps of 3.3v power, which equals only 10.725 watts. Further up the scale, the 150MHz chip uses 3.5 amps of 3.3v power (11.6 watts); the 166MHz unit draws 4.4 amps (14.5 watts); and the 200MHz processor uses 4.7 amps (15.5 watts).

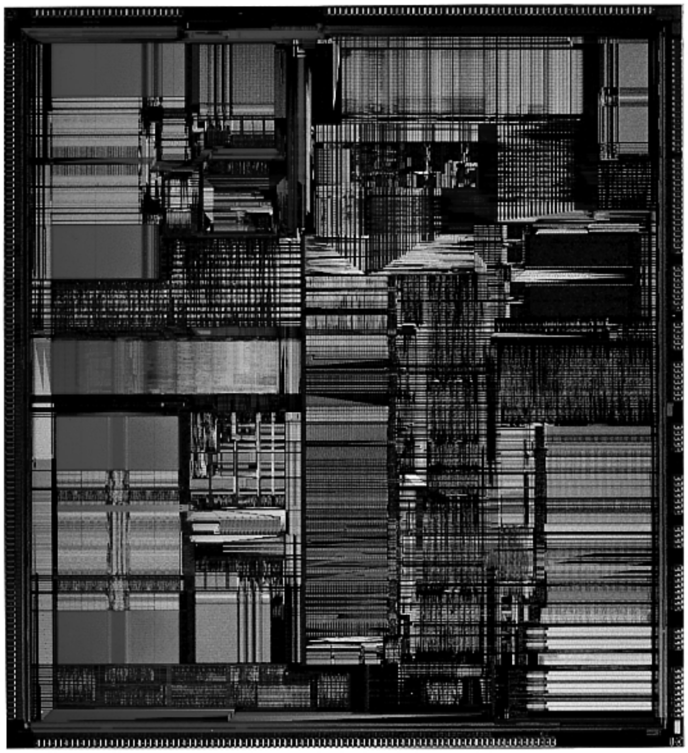

Figure 3.35 Pentium processor die. *Photograph used by permission of Intel Corporation.*

The second-generation Pentium processors come in a 296-pin SPGA form factor that is physically incompatible with the first-generation versions. The only way to upgrade from the first generation to the second is to replace the motherboard. The second-generation Pentium processors also have 3.3 million transistors—more than the earlier chips. The extra transistors exist because additional clock-control SL enhancements were added, along with an on-chip advanced programmable interrupt controller (APIC) and dual-processor interface.

The APIC and dual-processor interface are responsible for orchestrating dual-processor configurations in which two second-generation Pentium chips can process on the same motherboard simultaneously. Many of the Pentium motherboards designed for file servers come with dual Socket 7 specification sockets, which fully support the multiprocessing capability of the new chips. Software support for what usually is called symmetric multiprocessing (SMP) is being integrated into operating systems such as Windows NT and OS/2.

The second-generation Pentium processors use clock-multiplier circuitry to run the processor at speeds faster than the bus. The 150MHz Pentium processor, for example, can run at 2.5 times the bus frequency, which normally is 60MHz. The 200MHz Pentium processor can run at a 3x clock in a system using a 66MHz bus speed.

Virtually all Pentium motherboards have three speed settings: 50MHz, 60MHz, and 66MHz. Pentium chips are available with a variety of internal clock multipliers that cause the processor to operate at various multiples of these motherboard speeds. Refer to Table 3.7 for a list of the speeds of currently available Pentium processors and motherboards.

The core-to-bus frequency ratio or clock multiplier is controlled in a Pentium processor by two pins on the chip labeled BF1 and BF2. Table 3.22 shows how the state of the BFx pins affect the clock multiplication in the Pentium processor.

Table 3.22 Pentium BFx Pins and Clock Multipliers

BF1	BF2	Clock Multiplier	Bus Speed (MHz)	Core Speed (MHz)
0	1	3x	66	200
0	1	3x	60	180
0	1	3x	50	150
0	0	2.5x	66	166
0	0	2.5x	60	150
0	0	2.5x	50	125
1	0	2x/4x	66	133/266[1]
1	0	2x	60	120
1	0	2x	50	100
1	1	1.5x/3.5x	66	100/233[1]
1	1	1.5x	60	90
1	1	1.5x	50	75

1. The 233MHz and 266MHz processors have modified the 1.5x and 2x multipliers to 3.5x and 4x, respectively.

Not all chips support all the bus frequency (BF) pins or combinations of settings. In other words, some of the Pentium processors operate only at specific combinations of these settings or might even be fixed at one particular setting. Many of the later Pentium motherboards included jumpers or switches that enable you to control the BF pins and, therefore, alter the clock-multiplier ratio within the chip. In theory, you could run a 75MHz-rated Pentium chip at 133MHz by changing jumpers on the motherboard. This is called overclocking and is discussed in the section "Processor Speed Ratings," earlier in this chapter. What Intel has done to discourage overclockers in its most recent Pentiums is discussed near the end of the "Processor Manufacturing" section of this chapter.

A single-chip OverDrive upgrade currently is offered for second-generation Pentiums. These OverDrive chips are fixed at a 3x multiplier; they replace the existing Socket 5 or 7 CPU, increase processor speed up to 200MHz (with a 66MHz motherboard speed), and add MMX capability, as well. Simply stated, a Pentium 100, 133, or 166 system equipped with the OverDrive chip has a processor speed of 200MHz. Perhaps the best feature of these Pentium OverDrive chips is that they incorporate MMX technology. MMX provides greatly enhanced performance while running the multimedia applications that are so popular today.

If you have a Socket 7 motherboard, you might not need the special OverDrive versions of the Pentium processor that have built-in voltage regulators. Instead, you can purchase a standard Pentium or Pentium-compatible chip and replace the existing processor with it. You must be sure to set the multiplier and voltage settings so that they are correct for the new processor.

Pentium-MMX Processors

A third generation of Pentium processors (codenamed P55C) was released in January 1997, and incorporates what Intel calls MMX technology into the second-generation Pentium design (see Figure 3.36). These Pentium-MMX processors are available in clock rates of 66/166MHz, 66/200MHz, and

66/233MHz and in a mobile-only version, which is 66/266MHz. The MMX processors have a lot in common with other second-generation Pentiums, including superscalar architecture, multiprocessor support, on-chip local APIC controller, and power-management features. New features include a pipelined MMX unit, 16KB code, write-back cache (versus 8KB in earlier Pentiums), and 4.5 million transistors. Pentium-MMX chips are produced on an enhanced 0.35-micron CMOS silicon process that allows for a lower 2.8v voltage level. The newer mobile 233MHz and 266MHz processors are built on a 0.25-micron process and run on only 1.8 volts. With this newer technology, the 266 processor actually uses less power than the non-MMX 133.

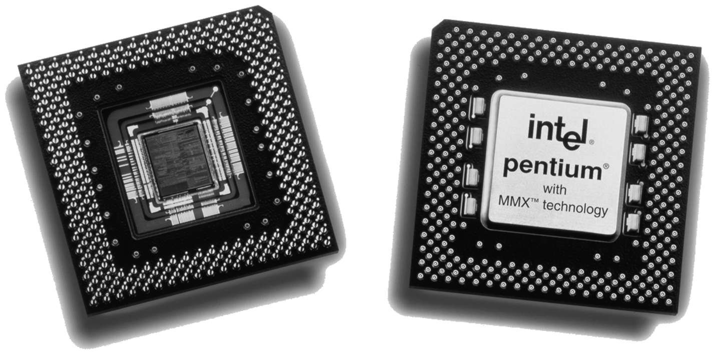

Figure 3.36 Pentium MMX. The left side shows the underside of the chip with the cover plate removed exposing the processor die. *Photograph used by permission of Intel Corporation.*

To use the Pentium-MMX, the motherboard must be capable of supplying the lower (2.8v or less) voltage these processors use. To enable a more universal motherboard solution with respect to these changing voltages, Intel has come up with the Socket 7 with VRM. The VRM is a socketed module that plugs in next to the processor and supplies the correct voltage. Because the module is easily replaced, reconfiguring a motherboard to support any of the voltages required by the newer Pentium processors is easy.

Of course, lower voltage is nice, but MMX is what this chip is really all about. MMX technology was developed by Intel as a direct response to the growing importance and increasing demands of multimedia and communication applications. Many such applications run repetitive loops of instructions that take vast amounts of time to execute. As a result, MMX incorporates a process Intel calls single instruction multiple data (SIMD), which enables one instruction to perform the same function on many pieces of data. Furthermore, 57 new instructions designed specifically to handle video, audio, and graphics data have been added to the chip.

To add maximum upgradability to the MMX Pentiums, a Pentium motherboard needs 321-pin processor sockets that fully meet the Intel Socket 7 specification. These also would include the VRM socket. If you have dual sockets, you can add a second Pentium processor to take advantage of SMP support in operating systems that support this feature.

Pentium Defects

Probably the most famous processor bug in history is the now legendary flaw in the Pentium FPU. It has often been called the FDIV bug because it affects primarily the FDIV (floating-point divide) instruction, although several other instructions that use division are also affected. Intel officially refers to this problem as Errata No. 23, titled “Slight precision loss for floating-point divides on specific operand pairs.” The bug has been fixed in the D1 or later steppings of the 60/66MHz Pentium processors, as well as the B5 and later steppings of the 75/90/100MHz processors. The 120MHz and higher processors are manufactured from later steppings, which do not include this problem. Tables listing all the variations of Pentium processors and steppings and how to identify them appear later in this chapter.

This bug caused a tremendous fervor when it first was reported on the Internet by a mathematician in October 1994. Within a few days, news of the defect had spread nationwide, and even people who did not have computers had heard about it. The Pentium incorrectly performed floating-point division calculations with certain number combinations, with errors anywhere from the third digit on up.

By the time the bug was publicly discovered outside of Intel, the company had already incorporated the fix into the next stepping of both the 60/66MHz and the 75/90/100MHz Pentium processor, along with the other corrections Intel had made.

After the bug was made public and Intel admitted to already knowing about it, a fury erupted. As people began checking their spreadsheets and other math calculations, many discovered they had also encountered this problem and did not know it. Others who had not encountered the problem had their faith in the core of their PCs very shaken. People had come to put so much trust in the PC that they had a hard time coming to terms with the fact that it might not even be capable of doing math correctly!

One interesting result of the fervor surrounding this defect is that people are less likely to implicitly trust their PCs and are therefore doing more testing and evaluating of important results. The bottom line is that if your information and calculations are important enough, you should implement some results tests. Several math programs were found to have problems. For example, a bug was discovered in the yield function of Excel 5.0 that some were attributing to the Pentium processor. In this case, the problem turned out to be the software, which has been corrected in later versions (5.0c and later).

Intel finally decided that in the best interest of the consumer and its public image, it would begin a lifetime replacement warranty on the affected processors. Therefore, if you ever encounter one of the Pentium processors with the Errata 23 floating-point bug, Intel will replace the processor with an equivalent one without this problem. Usually, all you have to do is call Intel and ask for the replacement. It will ship you a new part matching the ratings of the one you are replacing in an overnight shipping box. The replacement is free, including all shipping charges. You merely remove your old processor, replace it with the new one, and put the old one back in the box. Then you call the overnight service, who picks it up and sends it back. Intel will take a credit card number when you first call for the replacement only to ensure that the original defective chip is returned. As long as it gets the original CPU back within a specified amount of time, there will be no charges to you. Intel has indicated that these defective processors will be destroyed and will not be remarketed or resold in another form.

Testing for the FPU Bug

Testing a Pentium for this bug is relatively easy. All you have to do is execute one of the test division cases cited here and see whether your answer compares to the correct result.

The division calculation can be done in a spreadsheet (such as Lotus 1-2-3, Microsoft Excel, or any other), the Microsoft Windows built-in calculator, or any other calculating program that uses the FPU. Make sure that for the purposes of this test the FPU has not been disabled. That typically requires some special command or setting specific to the application and, of course, ensures that the test comes out correct, regardless of whether the chip is flawed.

The most severe Pentium floating-point errors occur as early as the third significant digit of the result. Here is an example of one of the more severe instances of the problem:

962,306,957,033 / 11,010,046 = 87,402.6282027341 (correct answer)

962,306,957,033 / 11,010,046 = 87,399.5805831329 (flawed Pentium)

Note

Note that your particular calculator program might not show the answer to the number of digits shown here. Most spreadsheet programs limit displayed results to 13 or 15 significant digits.

As you can see in the previous case, the error turns up in the third most significant digit of the result. In an examination of more than 5,000 integer pairs in the 5- to 15-digit range found to produce Pentium floating-point division errors, errors beginning in the sixth significant digit were the most likely to occur.

Here is another division problem that comes out incorrectly on a Pentium with this flaw:

4,195,835 / 3,145,727 = 1.33382044913624100 (correct answer)

4,195,835 / 3,145,727 = 1.33373906890203759 (flawed Pentium)

This one shows an error in the fifth significant digit. A variation on the previous calculation can be performed as follows:

x = 4,195,835

y = 3,145,727

z = x – (x/y)*y

4,195,835 – (4,195,835 / 3,145,727) × 3,145,727 = 0 (correct answer)

4,195,835 – (4,195,835 / 3,145,727) × 3,145,727 = 256 (flawed Pentium)

With an exact computation, the answer here should be 0. In fact, you will get 0 on most machines, including those using Intel 286, 386, and 486 chips. But, on the Pentium, the answer is 256!

Here is one more calculation you can try:

5,505,001 / 294,911 = 18.66665197 (correct answer)

5,505,001 / 294,911 = 18.66600093 (flawed Pentium)

This one represents an error in the sixth significant digit.

Several workarounds are available for this bug, but they extract a performance penalty. Because Intel has agreed to replace any Pentium processor with this flaw under a lifetime warranty replacement program, the best workaround is a free replacement!

Power Management Bugs

Starting with the second-generation Pentium processors, Intel added functions that enable these CPUs to be installed in energy-efficient systems. These are usually called *Energy Star systems* because they meet the specifications imposed by the EPA Energy Star program, but they are also unofficially called *green PCs* by many users.

Unfortunately, there have been several bugs with respect to these functions, causing them to either fail or be disabled. These bugs are in some of the functions in the power-management capabilities accessed through SMM. These problems are applicable only to the second-generation 75/90/100MHz processors because the first-generation 60/66MHz processors do not have SMM or power-management capabilities, and all higher-speed (120MHz and up) processors have the bugs fixed.

Most of the problems are related to the STPCLK# pin and the HALT instruction. If this condition is invoked by the chipset, the system will hang. For most systems, the only workaround for this problem is to disable the power-saving modes, such as suspend or sleep. Unfortunately, this means that your green PC won't be so green anymore! The best way to repair the problem is to replace the processor with a later stepping version that does not have the bug. These bugs affect the B1 stepping version of the 75/90/100MHz Pentiums, and they were fixed in the B3 and later stepping versions.

Pentium Processor Models and Steppings

We know that like software, no processor is truly ever perfect. From time to time, the manufacturers gather up what problems they have found and put into production a new stepping, which consists of a new set of masks that incorporate the corrections. Each subsequent stepping is better and more refined than the previous ones. Although no microprocessor is ever perfect, they come closer to perfection with each stepping. In the life of a typical microprocessor, a manufacturer might go through half a dozen or more such steppings.

See the previous editions of this book on the included CD-ROM for tables showing the Pentium processor steppings and revisions. This information is also available online from Intel via its Web site.

To determine the specifications of a given processor, you must look up the S-spec number in the table of processor specifications. To find your S-spec number, you have to read it off the chip directly. It can be found printed on both the top and bottom of the chip. If your heatsink is glued on, remove the chip and heatsink from the socket as a unit and read the numbers from the bottom of the chip. Then, you can look up the S-spec number in the Specification Guide Intel publishes (via its Web site); it tells you the specifications of that particular processor. Intel is introducing new chips all the time, so visit its Web site and search for the Pentium processor "Quick Reference Guide" in the developer portion of its site. There you will find a complete listing of all current processor specifications by S-spec number.

One interesting item to note is that several subtly different voltages are required by different Pentium processors. Table 3.23 summarizes the various processors and their required voltages.

Table 3.23 Pentium Processor Voltages

Model	Stepping	Voltage Spec.	Voltage Range
1	—	Std.	4.75–5.25v
1	—	5v1	4.90–5.25v
1	—	5v2	4.90–5.40v
1	—	5v3	5.15–5.40v
2+	B1-B5	Std.	3.135–3.465v
2+	C2+	Std.	3.135–3.600v
2+	—	VR	3.300–3.465v
2+	B1-B5	VRE	3.45–3.60v
2+	C2+	VRE	3.40–3.60v
4+	—	MMX	2.70–2.90v
4	3	Mobile	2.285–2.665v
4	3	Mobile	2.10–2.34v
8	1	Mobile	1.850–2.150v
8	1	Mobile	1.665–1.935v

Many of the newer Pentium motherboards have jumpers that allow for adjustments to the different voltage ranges. If you are having problems with a particular processor, it might not be matched correctly to your motherboard voltage output.

If you are purchasing an older, used Pentium system today, I recommend using only Model 2 (second-generation) or later version processors that are available in 75MHz or faster speeds. You should definitely get stepping C2 or later. Virtually all the important bugs and problems were fixed in the C2 and later releases. The newer Pentium processors have no serious bugs to worry about.

AMD-K5

The AMD-K5 is a Pentium-compatible processor developed by AMD and available as the PR75, PR90, PR100, PR120, PR133, and PR-166. Because it is designed to be physically and functionally compatible, any motherboard that properly supports the Intel Pentium should support the AMD-K5. However, a BIOS upgrade might be required to properly recognize the AMD-K5. AMD keeps a list of motherboards that have been tested for compatibility.

The K5 has the following features:

- 16KB instruction cache, 8KB write-back data cache
- Dynamic execution—branch prediction with speculative execution
- Five-stage, RISC-like pipeline with six parallel functional units
- High-performance floating-point unit
- Pin-selectable clock multiples of 1.5x and 2x

The K5 is sold under the P-Rating system, which means that the number on the chip does not indicate true clock speed, only apparent speed when running certain applications.

◀◀ See "AMD P-Ratings," p. 57.

Note that several of these processors do not run at their apparent rated speeds. For example, the PR-166 version actually runs at only 117 true MHz. Sometimes this can confuse the system BIOS, which might report the true speed rather than the P-Rating, which compares the chip against an Intel Pentium of that speed. AMD claims that because of architecture enhancements over the Pentium, they do not need to run the same clock frequency to achieve that same performance. Even with such improvements, AMD markets the K5 as a fifth-generation processor, just like the Pentium.

The AMD-K5 operates at 3.52 volts (VRE setting). Some older motherboards default to 3.3 volts, which is below specification for the K5 and could cause erratic operation.

Intel P6 (686) Sixth-Generation Processors

The P6 (686) processors represent a new generation with features not found in the previous generation units. The P6 processor family began when the Pentium Pro was released in November 1995. Since then, many other P6 chips have been released by Intel, all using the same basic P6 core processor as the Pentium Pro. Table 3.24 shows the variations in the P6 family of processors.

Table 3.24 Intel P6 Processor Variations

Pentium Pro	Original P6 processor, includes 256KB, 512KB, or 1MB of full-core speed L2 cache
Pentium II	P6 with 512KB of half-core speed L2 cache
Pentium II Xeon	P6 with 512KB, 1MB, or 2MB of full-core speed L2 cache
Celeron	P6 with no L2 cache
Celeron-A	P6 with 128KB of on-die full-core speed L2 cache
Pentium III	P6 with SSE (MMX2), 512KB of half-core speed L2 cache
Pentium IIPE	P6 with 256KB of full-core speed L2 cache

Table 3.24 Continued

Pentium IIIE	P6 with SSE (MMX2) plus 256KB of full-core speed L2 cache
Pentium III Xeon	P6 with SSE (MMX2), 512KB, 1MB, or 2MB of full-core speed L2 cache

Even more are expected in this family, including versions of the Pentium III with on-die full-core speed L2 cache, and faster versions of the Celeron.

The main new feature in the fifth-generation Pentium processors was the superscalar architecture, in which two instruction execution units could execute instructions simultaneously in parallel. Later fifth-generation chips also added MMX technology to the mix, as well. So then what did Intel add in the sixth-generation to justify calling it a whole new generation of chip? Besides many minor improvements, the real key features of all sixth-generation processors are Dynamic Execution and the Dual Independent Bus (DIB) architecture, plus a greatly improved superscalar design.

Dynamic Execution enables the processor to execute more instructions on parallel, so tasks are completed more quickly. This technology innovation is comprised of three main elements:

- *Multiple branch prediction*. Predict the flow of the program through several branches
- *Dataflow analysis*. Schedules instructions to be executed when ready, independent of their order in the original program
- *Speculative execution*. Increases the rate of execution by looking ahead of the program counter and executing instructions that are likely to be necessary

Branch prediction is a feature formerly found only in high-end mainframe processors. It enables the processor to keep the instruction pipeline full while running at a high rate of speed. A special fetch/decode unit in the processor uses a highly optimized branch prediction algorithm to predict the direction and outcome of the instructions being executed through multiple levels of branches, calls, and returns. It is like a chess player working out multiple strategies in advance of game play by predicting the opponent's strategy several moves into the future. By predicting the instruction outcome in advance, the instructions can be executed with no waiting.

Dataflow analysis studies the flow of data through the processor to detect any opportunities for out-of-order instruction execution. A special dispatch/execute unit in the processor monitors many instructions and can execute these instructions in an order that optimizes the use of the multiple superscalar execution units. The resulting out-of-order execution of instructions can keep the execution units busy even when cache misses and other data-dependent instructions might otherwise hold things up.

Speculative execution is the processor's capability to execute instructions in advance of the actual program counter. The processor's dispatch/execute unit uses dataflow analysis to execute all available instructions in the instruction pool and store the results in temporary registers. A retirement unit then searches the instruction pool for completed instructions that are no longer data dependent on other instructions to run, or which have unresolved branch predictions. If any such completed instructions are found, the results are committed to memory by the retirement unit or the appropriate standard Intel architecture in the order they were originally issued. They are then retired from the pool.

Dynamic Execution essentially removes the constraint and dependency on linear instruction sequencing. By promoting out-of-order instruction execution, it can keep the instruction units working rather than waiting for data from memory. Even though instructions can be predicted and executed out of order, the results are committed in the original order so as not to disrupt or change program flow. This enables the P6 to run existing Intel architecture software exactly as the P5 (Pentium) and previous processors did, just a whole lot more quickly!

The other main P6 architecture feature is known as the Dual Independent Bus. This refers to the fact that the processor has two data buses: one for the system (motherboard) and the other just for cache. This enables the cache memory to run at speeds previously not possible.

Previous P5 generation processors have only a single motherboard host processor bus, and all data, including cache transfers, must flow through it. The main problem with that is the cache memory was restricted to running at motherboard bus speed, which is 66MHz, 100MHz, or 133MHz. The solution was to essentially build in what is called a back-side bus to the processor, otherwise known as a dedicated cache bus. The L2 cache would then be connected to this bus and could run at any speed. The first implementation of this was in the Pentium Pro, where the L2 cache was built right into the processor package and ran at the full-core processor speed. Later, that proved to be too costly, so the L2 cache was moved outside the processor package and onto a cartridge module, which we now know as the Pentium II/III. With that design, the cache bus could run at any speed, with the first units running the cache at half-processor speed.

By having the cache on a back-side bus directly connected to the processor, the speed of the cache is scalable to the processor. In current PC architecture—66MHz Pentiums all the way through the 333MHz Pentium IIs—the motherboard runs at a speed of 66MHz. Faster Pentium II systems run a 100MHz motherboard bus and have clock speeds of 350MHz and higher. If the cache were restricted to the motherboard as is the case with Socket 7 (P5 processor) designs, the cache memory would have to remain at 66MHz, even though the processor was running as fast as 333MHz. With newer boards, the cache would be stuck at 100MHz, while the processor ran as fast as 500MHz or more. With the DIB design in the P6 processors, as the processor runs more quickly, at higher multiples of the motherboard speed, the cache increases by the same amount that the processor speed increases. The cache on the DIB is coupled to processor speed, so doubling the speed of the processor also doubles the speed of the cache.

The DIB architecture is necessary to have decent processor performance in the 300MHz and beyond range. Older Socket 7 (P5 processor) designs aren't capable of moving up to these higher speeds without suffering a tremendous performance penalty due to the slow motherboard-bound L2 cache. That is why Intel did not develop any Pentium (P5 class) processors beyond 266MHz; however, the P6 processors are available in speeds of up to 1000MHz or more.

Finally, the P6 architecture upgrades the superscalar architecture of the P5 processors by adding more instruction execution units and by breaking down the instructions into special micro-ops. This is where the CISC instructions are broken down into more RISC commands. The RISC-level commands are smaller and easier for the parallel instruction units to execute more efficiently. With this design, Intel has brought the benefits of a RISC processor—high-speed dedicated instruction execution—to the CISC world. Note that the P5 had only two instruction units, whereas the P6 has at least six separate dedicated instruction units. It is said to be three-way superscalar because the multiple instruction units can execute up to three instructions in one cycle.

Other improvements in efficiency also are included in the P6 architecture: built-in multiprocessor support, enhanced error detection and correction circuitry, and optimization for 32-bit software.

Rather than just being a faster Pentium, the Pentium Pro, Pentium II/III, and other sixth-generation processors have many feature and architectural improvements. The core of the chip is very RISC-like, whereas the external instruction interface is classic Intel CISC. By breaking down the CISC instructions into several RISC instructions and running them down parallel execution pipelines, the overall performance is increased.

Compared to a Pentium at the same clock speed, the P6 processors are faster—as long as you're running 32-bit software. The P6 Dynamic Execution is optimized for performance primarily when running 32-bit software, such as Windows NT. If you are using 16-bit software, such as Windows 95 or 98 (which still operate part time in a 16-bit environment) and most older applications, the P6 does not provide as marked a performance improvement over similarly speed-rated Pentium and Pentium-MMX processors. That's because the Dynamic Execution capability is not fully exploited. Because of this, Windows NT/2000 often are regarded as the most desirable operating systems for use with Pentium Pro/II/III/Celeron processors. Although this is not exactly true (a Pentium Pro/II/III/Celeron runs fine under Windows 95/98), Windows NT/2000 does take better advantage of the P6's capabilities. Note that it is really not so much the operating system but which applications you use. Software developers can take steps to gain the full advantages of the sixth-generation processors. This includes using modern compilers that can improve performance for all current Intel processors, writing 32-bit code where possible, and making code as predictable as possible to take advantage of the processor's Dynamic Execution multiple branch prediction capabilities.

Pentium Pro Processors

Intel's successor to the Pentium is called the Pentium Pro. The Pentium Pro was the first chip in the P6 or sixth-generation processor family. It was introduced in November 1995 and became widely available in 1996. The chip is a 387-pin unit that resides in Socket 8, so it is not pin compatible with earlier Pentiums. The new chip is unique among processors because it is constructed in a multichip module (MCM) physical format, which Intel calls a dual cavity PGA package. Inside the 387-pin chip carrier are two dies. One contains the actual Pentium Pro processor (shown in Figure 3.37), and the other contains a 256KB (the Pentium Pro with 256KB cache is shown in Figure 3.38), 512KB, or 1MB L2 cache. The processor die contains 5.5 million transistors, the 256KB cache die contains 15.5 million transistors, and the 512KB cache die(s) have 31 million transistors each—for a potential total of nearly 68 million transistors in a Pentium Pro with 1MB of internal cache! A Pentium Pro with 1MB cache has two 512KB cache die and a standard P6 processor die (see Figure 3.39).

Figure 3.37 Pentium Pro processor die. *Photograph used by permission of Intel Corporation.*

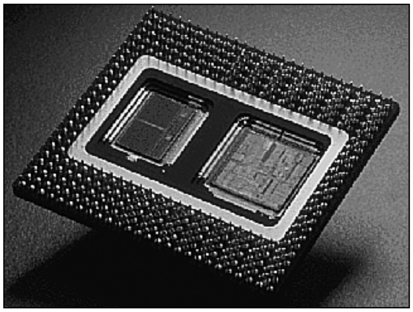

Figure 3.38 Pentium Pro processor with 256KB L2 cache (the cache is on the left side of the processor die). *Photograph used by permission of Intel Corporation.*

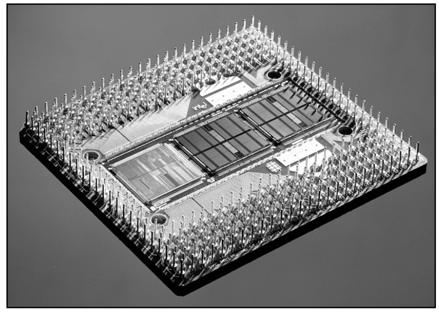

Figure 3.39 Pentium Pro processor with 1MB L2 cache (the cache is in the center and right portions of the die). *Photograph used by permission of Intel Corporation.*

The main processor die includes a 16KB split L1 cache with an 8KB two-way set associative cache for primary instructions and an 8KB four-way set associative cache for data.

Another sixth-generation processor feature found in the Pentium Pro is the DIB architecture, which addresses the memory bandwidth limitations of previous-generation processor architectures. Two buses make up the DIB architecture: the L2 cache bus (contained entirely within the processor package) and the processor-to-main memory system bus. The speed of the dedicated L2 cache bus on the Pentium Pro is equal to the full-core speed of the processor. This was accomplished by embedding the cache chips directly into the Pentium Pro package. The DIB processor bus architecture addresses processor-to-memory bus bandwidth limitations. It offers up to three times the performance bandwidth of the single-bus, "Socket 7" generation processors, such as the Pentium.

Table 3.25 shows Pentium Pro processor specifications. Table 3.26 shows the specifications for each model within the Pentium Pro family because many variations exist from model to model.

Table 3.25 Pentium Pro Family Processor Specifications

Introduced	November 1995
Maximum rated speeds	150MHz, 166MHz, 180MHz, 200MHz
CPU	2.5x, 3x
Internal registers	32-bit
External data bus	64-bit
Memory address bus	36-bit
Addressable memory	64GB
Virtual memory	64TB
Integral L1 cache size	8KB code, 8KB data (16KB total)
Integrated L2 cache bus	64-bit, full-core speed
Socket/Slot	Socket 8
Physical package	387-pin dual cavity PGA
Package dimensions	2.46 (6.25cm) × 2.66 (6.76cm)
Math coprocessor	Built-in FPU
Power management	SMM
Operating voltage	3.1v or 3.3v

Table 3.26 Pentium Pro Processor Specifications by Processor Model

Pentium Pro Processor (200MHz) with 1MB Integrated Level 2 Cache	
Introduction date	August 18, 1997
Clock speeds	200MHz (66MHz × 3)
Number of transistors	5.5 million (0.35 micron process), plus 62 million in 1MB L2 cache (0.35 micron)
Cache memory	8Kx2 (16KB) L1, 1MB core-speed L2
Die size	0.552 (14.0mm)
Pentium Pro Processor (200MHz)	
Introduction date	November 1, 1995
Clock speeds	200MHz (66MHz × 3)
iCOMP Index 2.0 rating	220
Number of transistors	5.5 million (0.35 micron process), plus 15.5 million in 256KB L2 cache (0.6 micron), or 31 million in 512KB L2 cache (0.35 micron)
Cache memory	8Kx2 (16KB) L1, 256KB or 512KB core-speed L2
Die size	0.552 inches per side (14.0mm)
Pentium Pro Processor (180MHz)	
Introduction date	November 1, 1995
Clock speeds	180MHz (60MHz × 3)
iCOMP Index 2.0 rating	197
Number of transistors	5.5 million (0.35 micron process), plus 15.5 million in 256KB L2 cache (0.6 micron)
Cache memory	8Kx2 (16KB) L1, 256KB core-speed L2
Die size	0.552 inches per side (14.0mm)
Pentium Pro Processor (166MHz)	
Introduction date	November 1, 1995
Clock speeds	166MHz (66MHz × 2.5)
Number of transistors	5.5 million (0.35 micron process), plus 31 million in 512KB L2 cache (0.35 micron)
Cache memory	8Kx2 L1, 512KB core-speed L2
Die size	0.552 inches per side (14.0mm)
Pentium Pro Processor (150MHz)	
Introduction date	November 1, 1995
Clock speeds	150MHz (60MHz × 2.5)
Number of transistors	5.5 million (0.6 micron process), plus 15.5 million in 256KB L2 cache (0.6 micron)
Cache memory	8Kx2 speed L2
Die size	0.691 inches per side (17.6mm)

As you saw in Table 3.5, performance comparisons on the iCOMP 2.0 Index rate a classic Pentium 200MHz at 142, whereas a Pentium Pro 200MHz scores an impressive 220. Just for comparison, note that a Pentium MMX 200MHz falls right about in the middle in regards to performance at 182. Keep in mind that using a Pentium Pro with any 16-bit software applications nullifies much of the performance gain shown by the iCOMP 2.0 rating.

Similar to the Pentium before it, the Pentium Pro runs clock multiplied on a 66MHz motherboard. The following table lists speeds for Pentium Pro processors and motherboards.

CPU Type/Speed	CPU Clock	Motherboard Speed
Pentium Pro 150	2.5x	60
Pentium Pro 166	2.5x	66
Pentium Pro 180	3x	60
Pentium Pro 200	3x	66

The integrated L2 cache is one of the really outstanding features of the Pentium Pro. By building the L2 cache into the CPU and getting it off the motherboard, the Pentium Pro can now run the cache at full processor speed rather than the slower 60MHz or 66MHz motherboard bus speed. In fact, the L2 cache features its own internal 64-bit back-side bus, which does not share time with the external 64-bit front-side bus used by the CPU. The internal registers and data paths are still 32-bit, as with the Pentium. By building the L2 cache into the system, motherboards can be cheaper because they no longer require separate cache memory. Some boards might still try to include cache memory in their designs, but the general consensus is that L3 cache (as it would be called) would offer less improvement with the Pentium Pro than with the Pentium.

One of the features of the built-in L2 cache is that multiprocessing is greatly improved. Rather than just SMP, as with the Pentium, the Pentium Pro supports a new type of multiprocessor configuration called the Multiprocessor Specification (MPS 1.1). The Pentium Pro with MPS enables configurations of up to four processors running together. Unlike other multiprocessor configurations, the Pentium Pro avoids cache coherency problems because each chip maintains a separate L1 and L2 cache internally.

Pentium Pro–based motherboards are pretty much exclusively PCI and ISA bus-based, and Intel is producing its own chipsets for these motherboards. The first chipset was the 450KX/GX (codenamed Orion), whereas the most recent chipset for use with the Pentium Pro is the 440LX (Natoma). Because of the greater cooling and space requirements, Intel designed the new ATX motherboard form factor to better support the Pentium Pro and other future processors, such as the Pentium II/III/4. Even so, the Pentium Pro can be found in all types of motherboard designs; ATX is not mandatory.

▶▶ See "Motherboard Form Factors," p. 194, and "Sixth-Generation and Seventh-Generation Chipsets," p. 246.

Some Pentium Pro system manufacturers were tempted to stick with the Baby-AT form factor. The big problem with the standard Baby-AT form factor is keeping the CPU properly cooled. The massive Pentium Pro processor consumes more than 25 watts and generates an appreciable amount of heat.

Four special VID pins are on the Pentium Pro processor. These pins can be used to support automatic selection of power supply voltage. Therefore, a Pentium Pro motherboard does not have voltage regulator jumper settings like most Pentium boards, which greatly eases the setup and integration of a Pentium Pro system. These pins are not actually signals, but are either an open circuit in the package or a short circuit to voltage. The sequence of opens and shorts define the voltage required by the processor. In addition to allowing for automatic voltage settings, this feature has been designed to support voltage specification variations on future Pentium Pro processors. The VID pins are named VID0 through VID3, and the definition of these pins is shown in Table 3.27. A 1 in this table refers to an open pin, and 0 refers to a short to ground. The voltage regulators on the motherboard should supply the voltage that is requested or disable itself.

Table 3.27 Pentium Pro Voltage Identification Definition

VID[3:0]	Voltage Setting	VID[3:0]	Voltage Setting
0000	3.5	1000	2.7
0001	3.4	1001	2.6
0010	3.3	1010	2.5
0011	3.2	1011	2.4
0100	3.1	1100	2.3
0101	3.0	1101	2.2
0110	2.9	1110	2.1
0111	2.8	1111	No CPU present

Most Pentium Pro processors run at 3.3v, but a few run at 3.1v. Although those are the only versions available now, support for a wider range of VID settings will benefit the system in meeting the power requirements of future Pentium Pro processors. Note that the 1111 (or all opens) ID can be used to detect the absence of a processor in a given socket.

The Pentium Pro never did become very popular on the desktop, but it did find a niche in file-server applications primarily because of the full-core speed high-capacity internal L2 cache.

Pentium II Processors

Intel revealed the Pentium II in May 1997. Prior to its official unveiling, the Pentium II processor was popularly referred to by its codename, Klamath, and was surrounded by much speculation throughout the industry. The Pentium II is essentially the same sixth-generation processor as the Pentium Pro, with MMX technology added (which included double the L1 cache and 57 new MMX instructions); however, there are a few twists to the design. The Pentium II processor die is shown in Figure 3.40.

From a physical standpoint, it is truly something new. Abandoning the chip in a socket approach used by virtually all processors up until this point, the Pentium II chip is characterized by its SEC cartridge design. The processor, along with several L2 cache chips, is mounted on a small circuit board (much like an oversized-memory SIMM) as shown in Figure 3.41, and the circuit board is then sealed in a metal and plastic cartridge. The cartridge is then plugged into the motherboard through an edge connector called Slot 1, which looks very much like an adapter card slot.

The two variations on these cartridges are called SECC (single edge contact cartridge) and SECC2. Figure 3.42 shows a diagram of the SECC package; Figure 3.43 shows the SECC2 package.

As you can see from these figures, the SECC2 version is cheaper to make because it uses fewer overall parts. It also allows for a more direct heatsink attachment to the processor for better cooling. Intel transitioned from SECC to SECC2 in the beginning of 1999; all later PII chips, and the Slot 1 PIII chips that followed, use the improved SECC2 design.

By using separate chips mounted on a circuit board, Intel can build the Pentium II much less expensively than the multiple die within a package used in the Pentium Pro. Intel can also use cache chips from other manufacturers and more easily vary the amount of cache in future processors compared to the Pentium Pro design.

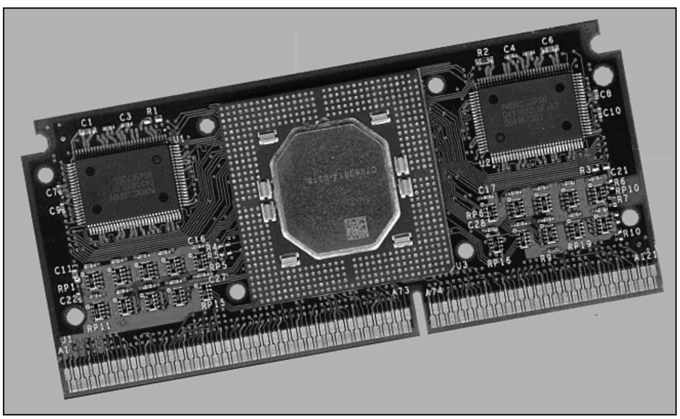

Figure 3.41 Pentium II processor board (inside SEC cartridge). *Photograph used by permission of Intel Corporation.*

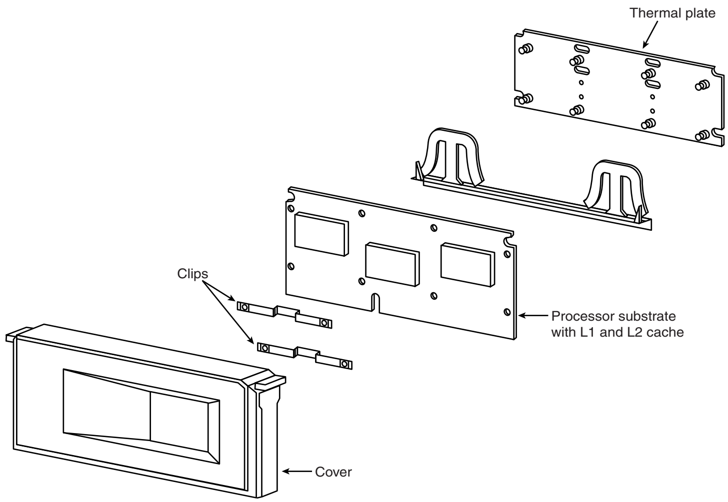

Figure 3.42 SECC components showing an enclosed processor board.

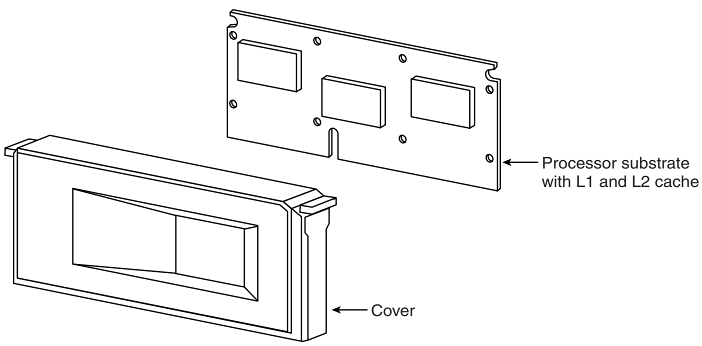

Figure 3.43 Two SECC, rev. 2 components showing a half-enclosed processor board.

Intel has offered Pentium II processors with the following speeds:

CPU Type/Speed	CPU Clock	Motherboard Speed
Pentium II 233MHz	3.5x	66MHz
Pentium II 266MHz	4x	66MHz
Pentium II 300MHz	4.5x	66MHz
Pentium II 333MHz	5x	66MHz
Pentium II 350MHz	3.5x	100MHz
Pentium II 400MHz	4x	100MHz
Pentium II 450MHz	4.5x	100MHz

The Pentium II processor core has 7.5 million transistors and is based on Intel's advanced P6 architecture. The Pentium II started out using .35 micron process technology, although the 333MHz and faster Pentium IIs are based on 0.25-micron technology. This enables a smaller die, allowing increased core frequencies and reduced power consumption. At 333MHz, the Pentium II processor delivers a 75%–150% performance boost, compared to the 233MHz Pentium processor with MMX technology, and approximately 50% more performance on multimedia benchmarks. As shown earlier in Table 3.3, the iCOMP 2.0 Index rating for the Pentium II 266MHz chip is more than twice as fast as a classic Pentium 200MHz.

Aside from speed, the best way to think of the Pentium II is as a Pentium Pro with MMX technology instructions and a slightly modified cache design. It has the same multiprocessor scalability as the Pentium Pro, as well as the integrated L2 cache. The 57 new multimedia-related instructions carried over from the MMX processors and the capability to process repetitive loop commands more efficiently are included as well. Also included as a part of the MMX upgrade is double the internal L1 cache from the Pentium Pro (from 16KB total to 32KB total in the Pentium II).

Maximum power usage for the Pentium II is shown in the following table:

Core Speed	Power Draw	Process	Voltage
450MHz	27.1w	0.25 micron	2.0v
400MHz	24.3w	0.25 micron	2.0v
350MHz	21.5w	0.25 micron	2.0v
333MHz	23.7w	0.25 micron	2.0v
300MHz	43.0w	0.35 micron	2.8v
266MHz	38.2w	0.35 micron	2.8v
233MHz	34.8w	0.35 micron	2.8v

You can see that the highest speed 450MHz version of the Pentium II actually uses less power than the slowest original 233MHz version! This was accomplished by using the smaller 0.25-micron process and running the processor on a lower voltage of only 2.0v. Future Pentium III processors will use the 0.25- and 0.18-micron processes and even lower voltages to continue this trend.

The Pentium II includes Dynamic Execution, which describes unique performance-enhancing developments by Intel and was first introduced in the Pentium Pro processor. Major features of Dynamic Execution include multiple branch prediction, which speeds execution by predicting the flow of the program through several branches; dataflow analysis, which analyzes and modifies the program order to execute instructions when ready; and speculative execution, which looks ahead of the program counter and executes instruction that are likely to be needed. The Pentium II processor expands on these capabilities in sophisticated and powerful new ways to deliver even greater performance gains.

Similar to the Pentium Pro, the Pentium II also includes DIB architecture. The term *Dual Independent Bus* comes from the existence of two independent buses on the Pentium II processor—the L2 cache bus and the processor–to–main-memory system bus. The Pentium II processor can use both buses simultaneously, thus getting as much as twice as much data in and out of the Pentium II processor than a single-bus architecture processor. The DIB architecture enables the L2 cache of the 333MHz Pentium II processor to run 2 1/2 times as fast as the L2 cache of Pentium processors. As the frequency of future Pentium II processors increases, so will the speed of the L2 cache. Also, the pipelined system bus enables simultaneous parallel transactions instead of singular sequential transactions. Together, these DIB architecture improvements offer up to three times the bandwidth performance over a single-bus architecture as with the regular Pentium.

Table 3.28 shows the general Pentium II processor specifications. Table 3.29 shows the specifications that vary by model for the models that have been introduced to date.

Table 3.28 Pentium II General Processor Specifications

Bus Speeds	66MHz, 100MHz
CPU clock multiplier	3.5x, 4x, 4.5x, 5x
CPU speeds	233MHz, 266MHz, 300MHz, 333MHz, 350MHz, 400MHz, 450MHz
Cache memory	16Kx2 (32KB) L1, 512KB 1/2-speed L2
Internal registers	32-bit
External data bus	64-bit system bus w/ ECC; 64-bit cache bus w/ optional ECC
Memory address bus	36-bit
Addressable memory	64GB
Virtual memory	64TB
Physical package	Single edge contact cartridge (S.E), 242 pins
Package dimensions	5.505 in. (12.82cm)×2.473 inches (6.28cm)×0.647 in. (1.64cm)
Math coprocessor	Built-in FPU
Power management	SMM

Table 3.29 Pentium II Specifications by Model

Pentium II MMX Processor (350MHz, 400MHz, and 450MHz)	
Introduction date	April 15, 1998
Clock speeds	350MHz (100MHz×3.5), 400MHz (100MHz ×4), and 450MHz (100MHz×4.5)
iCOMP Index 2.0 rating	386 (350MHz), 440 (400MHz), and 483 (450MHz)
Number of transistors	7.5 million (0.25-micron process), plus 31 million in 512KB L2 cache
Cacheable RAM	4GB
Operating voltage	2.0v
Slot	Slot 2
Die size	0.400 inches per side (10.2mm)
Mobile Pentium II Processor (266MHz, 300MHz, 333MHz, and 366MHz)	
Introduction date	January 25, 1999
Clock speeds	266MHz, 300MHz, 333MHz, and 366MHz
Number of transistors	27.4 million (0.25-micron process), 256KB on-die L2 cache
Ball grid array (BGA)	Number of balls = 615
Dimensions	Width = 31mm; length = 35mm
Core voltage	1.6 volts
Thermal design power ranges by frequency	366MHz = 9.5 watts; 333MHz = 8.6 watts; 300MHz = 7.7 watts; 266MHz = 7.0 watts

Table 3.29 Continued

	Pentium II MMX Processor (333MHz)
Introduction date	January 26, 1998
Clock speed	333MHz (66MHz×5)
iCOMP Index 2.0 rating	366
Number of transistors	7.5 million (0.25-micron process), plus 31 million in 512KB L2 cache
Cacheable RAM	512MB
Operating voltage	2.0v
Slot	Slot 1
Die size	0.400 inches per side (10.2mm)
	Pentium II MMX Processor (300MHz)
Introduction date	May 7, 1997
Clock speed	300MHz (66MHz×4.5)
iCOMP Index 2.0 rating	332
Number of transistors	7.5 million (0.35-micron process), plus 31 million in 512KB L2 cache
Cacheable RAM	512MB
Die size	0.560 inches per side (14.2mm)
	Pentium II MMX Processor (266MHz)
Introduction date	May 7, 1997
Clock speed	266MHz (66MHz×4)
iCOMP Index 2.0 rating	303
Number of transistors	7.5 million (0.35-micron process), plus 31 million in 512KB L2 cache
Cacheable RAM	512MB
Slot	Slot 1
Die size	0.560 inches per side (14.2mm)
	Pentium II MMX Processor (233MHz)
Introduction date	May 7, 1997
Clock speed	233MHz (66MHz×3.5)
iCOMP Index 2.0 rating	267
Number of transistors	7.5 million (0.35-micron process), plus 31 million in 512KB L2 cache
Cacheable RAM	512MB
Slot	Slot 1
Die size	0.560 inches per side (14.2mm)

As you can see from Table 3.30, the Pentium II can handle up to 64GB of physical memory. Similar to the Pentium Pro, the CPU incorporates DIB architecture. Therefore, chip has two independent buses: one for accessing the L2 cache and the other for accessing main memory. These dual buses can operate simultaneously, greatly accelerating the flow of data within the system. The L1 cache always runs at full-core speeds because it is mounted directly on the processor die. The L2 cache in the Pentium II normally runs at half-core speed, which saves money and allows for less expensive cache chips to be used. For example, in a 333MHz Pentium II, the L1 cache runs at a full 333MHz, whereas the L2 cache runs at 167MHz. Even though the L2 cache is not at full-core speed as it was with the Pentium Pro, this is still far superior to having cache memory on the motherboard running at the 66MHz motherboard speed of most Socket 7 Pentium designs. Intel claims that the DIB architecture in the Pentium II enables up to three times the bandwidth of normal single-bus processors, such as the original Pentium.

By removing the cache from the processor's internal package and using external chips mounted on a substrate and encased in the cartridge design, Intel can now use more cost-effective cache chips and more easily scale the processor up to higher speeds. The Pentium Pro was limited in speed to 200MHz, largely due to the inability to find affordable cache memory that runs any faster. By running the cache memory at half-core speed, the Pentium II can run up to 400MHz while still using 200MHz-rated cache chips. To offset the half-core speed cache used in the Pentium II, Intel doubled the basic amount of integrated L2 cache from 256KB standard in the Pro to 512KB standard in the Pentium II.

Note that the tag RAM included in the L2 cache enables up to 512MB of main memory to be cacheable in PII processors from 233MHz to 333MHz. The 350MHz, 400MHz, and faster versions include an enhanced tag-RAM that allows up to 4GB of main memory to be cacheable. This is very important if you ever plan on adding more than 512MB of memory. In that case, you would definitely want the 350MHz or faster version; otherwise, memory performance would suffer.

The system bus of the Pentium II provides "glueless" support for up to two processors. This enables low-cost, two-way multiprocessing on the L2 cache bus. These system buses are designed especially for servers or other mission-critical system use where reliability and data integrity are important. All Pentium IIs also include parity-protected address/request and response system bus signals with a retry mechanism for high data integrity and reliability.

To install the Pentium II in a system, a special processor-retention mechanism is required. This consists of a mechanical support that attaches to the motherboard and secures the Pentium II processor in Slot 1 to prevent shock and vibration damage. Retention mechanisms should be provided by the motherboard manufacturer. (For example, the Intel Boxed AL440FX and DK440LX motherboards include a retention mechanism, plus other important system integration components.)

The Pentium II can generate a significant amount of heat that must be dissipated. This is accomplished by installing a heatsink on the processor. Many of the Pentium II processors use an active heatsink that incorporates a fan. Unlike heatsink fans for previous Intel boxed processors, the Pentium II fans draw power from a three-pin power header on the motherboard. Most motherboards provide several fan connectors to supply this power.

Special heatsink supports are necessary to furnish mechanical support between the fan heatsink and support holes on the motherboard. Normally, a plastic support is inserted into the heatsink holes in the motherboard next to the CPU, before installing the CPU/heatsink package. Most fan heatsinks have two components: a fan in a plastic shroud and a metal heatsink. The heatsink is attached to the processor's thermal plate and should not be removed. The fan can be removed and replaced if necessary—for example, if it has failed. Figure 3.44 shows the SEC assembly with fan, power connectors, mechanical supports, and the slot and support holes on the motherboard.

The following tables show the specifications unique to certain versions of the Pentium II processor.

To identify exactly which Pentium II processor you have and what its capabilities are, look at the specification number printed on the SEC cartridge. You will find the specification number in the dynamic mark area on the top of the processor module. See Figure 3.45 to locate these markings.

After you have located the specification number (actually, it is an alphanumeric code), you can look it up in Table 3.30 to see exactly which processor you have.

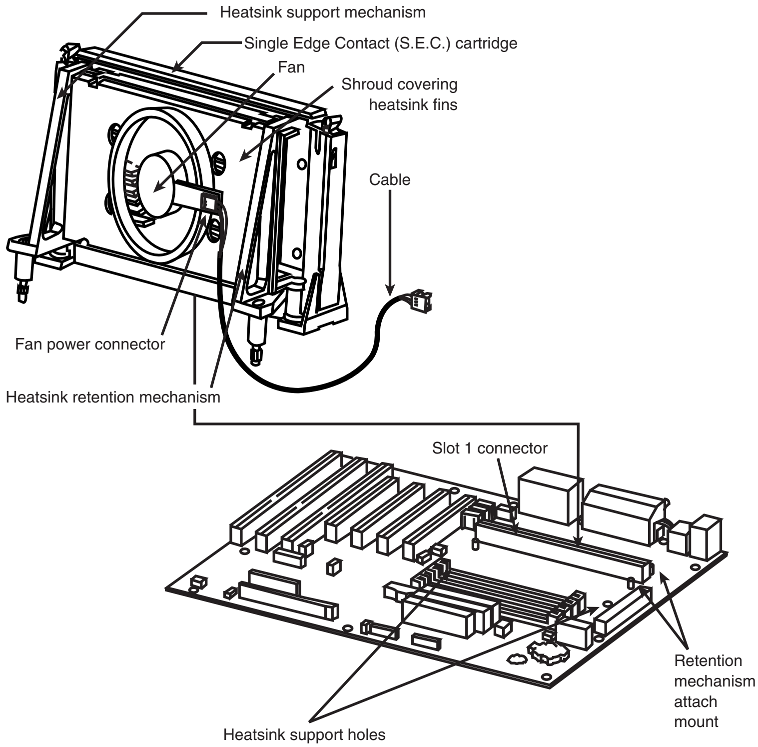

Figure 3.44 Pentium II/III processor and heatsink assembly.

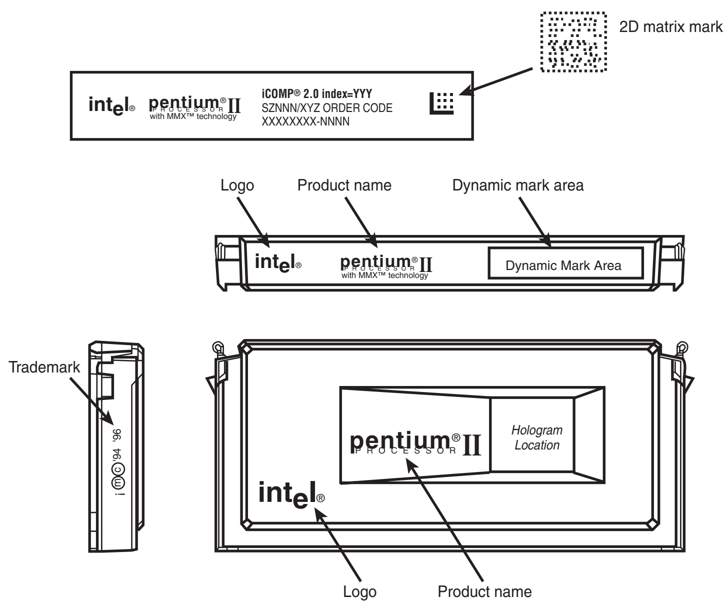

Figure 3.45 Pentium II/III SECC.

For example, a specification number of SL2KA identifies the processor as a Pentium II 333MHz running on a 66MHz system bus, with an ECC L2 cache—and indicates that this processor runs on only 2.0 volts. The stepping is also identified, and by looking in the Pentium II Specification Update Manual published by Intel, you could figure out exactly which bugs were fixed in that revision.

Table 3.30 Basic Pentium II Processor Identification Information

S-spec	Core Stepping	CPUID	Core/Bus Speed (MHz)	L2 Cache Size (MB)	L2 Cache Type	CPU Package	Notes (see footnotes)

SECC = Single edge contact cartridge

SECC2 = Single edge contact cartridge revision 2

PLGA = Plastic land grid array

OLGA = Organic land grid array

CPUID = The internal ID returned by the CPUID instruction

ECC = Error correcting code

1. *This is a boxed Pentium II processor with an attached fan heatsink.*
2. *These processors have an enhanced L2 cache, which can cache up to 4GB of main memory. Other standard PII processors can cache only up to 512MB of main memory.*
3. *These boxed processors might have packaging that incorrectly indicates ECC support in the L2 cache.*
4. *This is a boxed Pentium II OverDrive processor with an attached fan heatsink, designed for upgrading Pentium Pro (Socket 8) systems.*
5. *These parts operate at only the specified clock multiplier frequency ratio at which they were manufactured. They can be overclocked only by increasing bus speed.*

The two variations of the SECC2 cartridge vary by the type of processor core package on the board. The plastic land grid array (PLGA) is the older type of packaging used in previous SECC cartridges as well and is being phased out. Taking its place is the newer organic land grid array (OLGA), which is a processor core package that is smaller and easier to manufacture. It also enables better thermal transfer between the processor die and the heatsink, which is attached directly to the top of the OLGA chip package. Figure 3.46 shows the open back side (where the heatsink would be attached) of SECC2 processors with PLGA and OLGA cores.

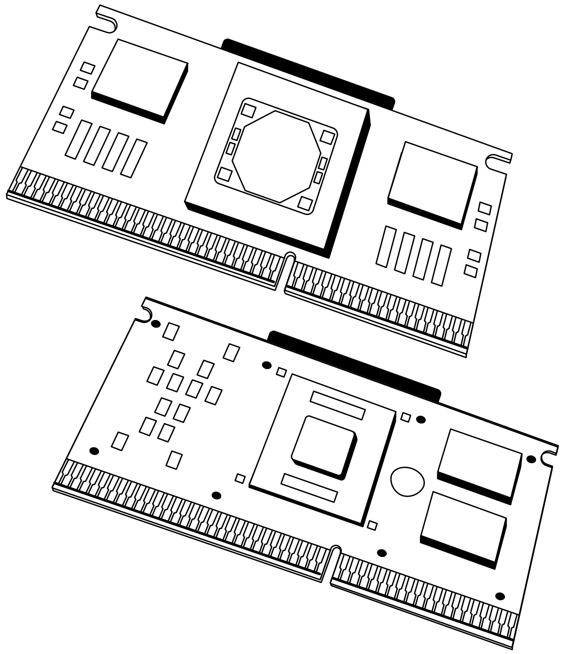

Figure 3.46 SECC2 processors with PLGA and OLGA cores.

Pentium II motherboards have an onboard voltage regulator circuit designed to power the CPU. Currently, some Pentium II processors run at several different voltages, so the regulator must be set to supply the correct voltage for the specific processor you are installing. As with the Pentium Pro and unlike the older Pentium, no jumpers or switches must be set; the voltage setting is handled completely automatically through the VID pins on the processor cartridge. Table 3.31 shows the relationship between the pins and the selected voltage.

Table 3.31 Slot 1 and Socket 370 Voltage ID Pin Definitions

VID4	VID3	VID2	VID1	VID0	Voltage
0	1	1	1	1	1.30

0 = Processor pin connected to Vss

1 = Open on processor

VID0–VID3 used on Socket 370

Socket 370 supports 1.30–2.05V settings only.

VID0-VID4 used on Slot 1

Slot 1 supports 1.30–3.5V settings.

To ensure the system is ready for all Pentium II processor variations, the values in **bold** must be supported. Most Pentium II processors run at 2.8v, with some newer ones at 2.0v.

The Pentium II Mobile Module is a Pentium II for notebooks that includes the North Bridge of the high-performance 440BX chipset. This is the first chipset on the market that allows 100MHz processor bus operation, although that is currently not supported in the mobile versions. The 440BX chipset was released at the same time as the 350MHz and 400MHz versions of the Pentium II; it is the recommended minimum chipset for any new Pentium II motherboard purchases.

Newer variations on the Pentium II include the Pentium IIPE, which is a mobile version that includes 256KB of L2 cache directly integrated into the die. Therefore, it runs at full-core speed, making it faster than the desktop Pentium II because the desktop chips use half-speed L2 cache.

Celeron

The Celeron processor is a P6 with the same processor core as the Pentium II in the original two versions and now the same core as the PIII in the latest version. It is mainly designed for lower-cost PCs in the $600 or less price category. The best “feature” is that although the cost is low, the performance is not. In fact, because of the superior integrated cache design of all but the first units, the Celeron outperforms the Pentium II at the same speed and at a lower cost.

Most of the features for the Celeron are the same as the Pentium II and III because it uses the same internal processor core. The main differences are in packaging and L2 cache design.

Up until recently, all Celeron processors were available in a package called the single edge processor package (SEPP or SEP package). The SEP package is basically the same Slot 1 design as the SECC used in the Pentium II/III, with the exception of the fancy plastic cartridge cover. This cover is deleted in the Celeron, making it cheaper to produce and sell. Essentially, the Celeron uses the same circuit board as is inside the Pentium II package.

◀◀ See “Single Edge Contact and Single Edge Processor Packaging,” p. 80.

Even without the plastic covers, the Slot 1 packaging was more expensive than it should have been. This was largely due to the processor retention mechanisms (stands) required to secure the processor into Slot 1 on the motherboard, as well as the larger and more complicated heatsinks required. This, plus competition from the lower-end Socket 7 systems using primarily AMD processors, led Intel to introduce the Celeron in a socketed form. The socket is called PGA-370 or Socket 370 because it has 370 pins. The processor package designed for this socket is called the plastic pin grid array (PPGA) package (see Figure 3.47) or flip chip PGA (FC-PGA). Both the PPGA and FC-PGA packages plug into the 370 pin socket and allow for lower-cost, lower-profile, and smaller systems because of the less expensive processor retention and cooling requirements of the socketed processor.

◀◀ See “Socket 370 (PGA-370),” p. 90.

All Celeron processors at 433MHz and lower have been available in the SEPP that plugs into the 242-contact slot connector. The 300MHz and higher versions also are available in the PPGA package. This means that the 300MHz to 433MHz have been available in both packages, whereas the 466MHz and higher-speed versions are available only in the PPGA.

Motherboards that include Socket 370 can accept the PGA versions of both the Celeron and Pentium III in most cases. If you want to use a Socket 370 version of the Celeron in a Slot 1 motherboard, slot-to-socket adapters (usually called slot-kets) are available for about $10–$20 that plug into Slot 1 and incorporate a Socket 370 on the card. Figure 3.48 shows a typical slot-ket adapter.

Highlights of the Celeron include

- Available at 300MHz (300A) and higher core frequencies with 128KB on-die L2 cache; 300MHz and 266MHz core frequencies without L2 cache
- L2 cache supports up to 4GB RAM address range and ECC
- Uses same P6 core processor as the Pentium II (266MHz through 533MHz) and now the Pentium III (533A MHz and higher)
- Dynamic execution microarchitecture
- Operates on a 66MHz CPU bus (future versions will likely also use the 100MHz bus)
- Specifically designed for lower-cost value PC systems

- Includes MMX technology; Celeron 533A and higher include SSE
- More cost-effective packaging technology, including SEP, PPGA, or FC-PGA packages
- Integrated 32KB L1 cache, implemented as separate 16KB instruction and 16KB data caches
- Integrated thermal diode for temperature monitoring

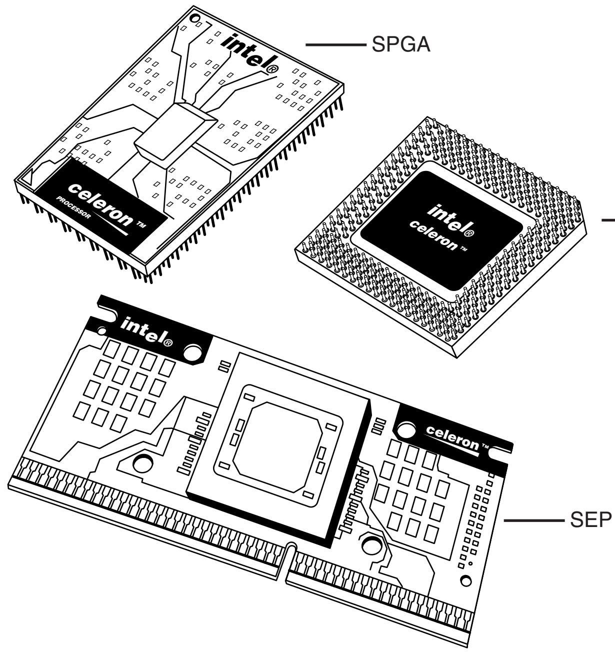

Figure 3.47 Celeron processors in the FC-PGA, PPGA, and SEP packages.

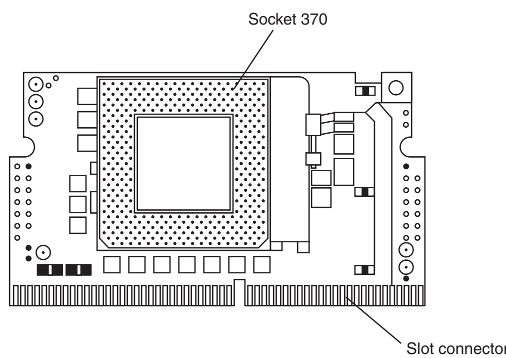

Figure 3.48 Slot-ket adapter for installing PPGA processors in Slot 1 motherboards.

The Intel Celeron processors from the 300A and higher include integrated 128KB L2 cache. The core for the 300A through 533MHz versions that are based on the Pentium II core include 19 million transistors because of the addition of the integrated 128KB L2 cache. The 533A and faster versions are based on the Pentium III core and incorporate 28.1 million transistors. The Pentium III–based versions actually have 256KB of L2 cache on the die; however, 128KB is disabled, leaving 128KB of functional L2 cache. This was done because it was cheaper for Intel to simply make the Pentium III and Celeron using the same die and just disable part of the cache on the Celeron versions, rather than coming up with a unique die for the newer Celerons. The Pentium III–based Celeron processors also support the SSE in addition to MMX instructions. The older Celerons based on the Pentium II core support only MMX.

All the Celerons in SEPP and PPGA form are manufactured using the 0.25-micron process, whereas those in FC-PGA form are made using an even better 0.18-micron process. The smaller process reduces processor heat and enables higher speeds. Table 3.35 shows the power consumed by the various Celeron processors.

Figure 3.49 shows the Intel Celeron processor identification information. Figure 3.50 shows the Celeron's PPGA processor markings, which can be used to identify the chip and prevent being duped by a re-marked chip.

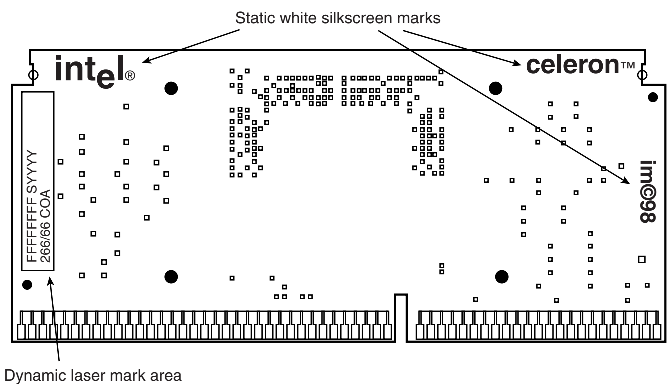

Figure 3.49 Celeron SEPP processor markings.

Note

The markings on the processor identify the following information:

SYYYY = S-spec. number

FFFFFFFF = FPO # (test lot traceability #)

COA = Country of assembly

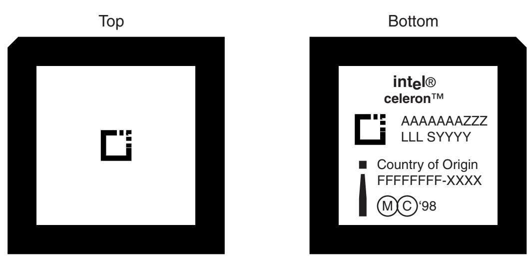

Figure 3.50 Celeron PPGA processor markings.

Note

The PPGA processor markings identify the following information:

AAAAAAA = Product code

ZZZ = Processor speed (MHz)

LLL = Integrated L2 cache size (in kilobytes)

SYYYY = S-spec. number

FFFFFFFF-XXXX = Assembly lot tracking number

Table 3.32 shows all the available variations of the Celeron, indicated by the S-specification number.

Pentium III

The Pentium III processor, shown in Figure 3.51, was first released in February 1999 and introduced several new features to the P6 family. The most important advancements are the streaming SSE and the integrated on-die L2 cache in the later versions. SSE consists of 70 new instructions that dramatically enhance the performance and possibilities of advanced imaging, 3D, streaming audio, video, and speech-recognition applications.

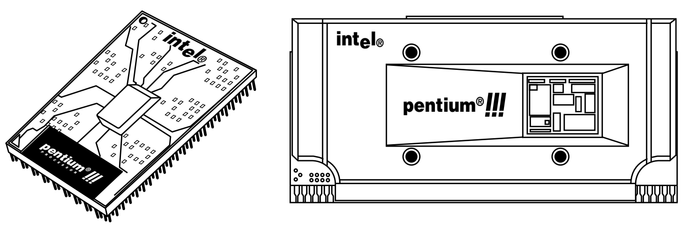

Figure 3.51 Pentium III processor in SECC2 (Slot 1) and FC-PGA (Socket 370) packages.

Originally based on Intel's advanced 0.25-micron CMOS process technology, the PIII core started out with more than 9.5 million transistors. In late 1999, Intel shifted to a 0.18- micron process die (codenamed Coppermine) and added 256KB of on-die L2 cache, which brought the transistor count to a whopping 28.1 million! The Pentium III is available in speeds from 450MHz through 1000MHz and beyond, as well as server versions with larger or faster cache called Xeon. The Pentium III also incorporates advanced features such as a 32KB L1 cache and either half-core speed 512KB L2 cache or full-core speed on-die 256KB L2 with cacheability for up to 4GB of addressable memory space. The PIII also can be used in dual-processing systems with up to 64GB of physical memory. A self-reportable processor serial number gives security, authentication, and system management applications a powerful new tool for identifying individual systems.

Pentium III processors are available in Intel's SECC2 form factor, which is replacing the more expensive older SEC packaging. The SECC2 package covers only one side of the chip and allows for better heatsink attachment and less overall weight. It is also less expensive.

Architectural features of the Pentium III processor include

- *Streaming SIMD Extensions*. Seventy new instructions for dramatically faster processing and improved imaging, 3D streaming audio and video, Web access, speech recognition, new user interfaces, and other graphics and sound-rich applications.

- *Intel processor serial number*. The processor serial number, the first of Intel's planned building blocks for PC security, serves as an electronic serial number for the processor and, by extension, its system or user. This enables the system/user to be identified by networks and applications. The processor serial number will be used in applications that benefit from stronger forms of system and user identification, such as the following:
  - *Applications using security capabilities*. Managed access to new Internet content and services; electronic document exchange.
  - *Manageability applications*. Asset management; remote system load and configuration.
  - *Intel MMX technology.*
  - *Dynamic Execution technology.*
  - *Those incorporating an on-die diode*. This can be used to monitor the die temperature for thermal management purposes.

Most of the Pentium III processors will be made in the improved SECC2 packaging or, even better, the FC-PGA package, which is much less expensive to produce and enables a more direct attachment of the heatsink to the processor core for better cooling. The FC-PGA version plugs into Socket 370 but can be used in Slot 1 with a slot-ket adapter.

All Pentium III processors have either 512KB or 256KB of L2 cache, which runs at either half-core or full-core speed. Xeon versions have 512KB, 1MB, or 2MB of L2 cache that runs at full-core speed. These are more expensive versions designed for servers and workstations.

All PIII processor L2 caches can cache up to 4GB of addressable memory space and include ECC capability.

Pentium III processors can be identified by their markings, which are found on the top edge of the processor cartridge. Figure 3.52 shows the format and meaning of the markings.

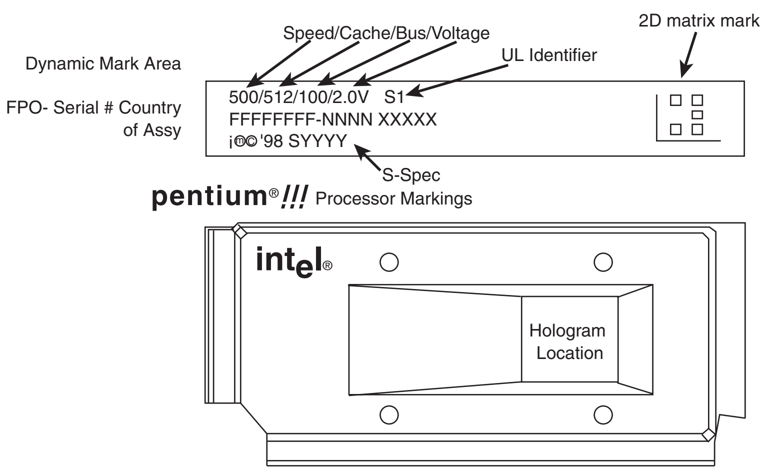

Figure 3.52 Pentium III processor markings.

Table 3.33 shows the available variations of the Pentium III, indicated by the S-specification number.

SECC = Single edge contact cartridge

SECC2 = Single edge contact cartridge revision 2

Pentium III processors are all clock multiplier locked. This is a means to prevent processor fraud and overclocking by making the processor work only at a given clock multiplier. Unfortunately, this feature can be bypassed by making modifications to the processor under the cartridge cover, and unscrupulous individuals have been selling lower-speed processors re-marked as higher speeds. It pays to purchase your systems or processors from direct Intel distributors or high-end dealers who do not engage in these practices.

Pentium II/III Xeon

The Pentium II and III processors are available in special high-end versions called Xeon processors. Originally introduced in June 1998 in Pentium II versions, later Pentium III versions were introduced in March 1999. These differ from the standard Pentium II and III in three ways: packaging, cache size, and cache speed.

Xeon processors use a larger SEC cartridge than the standard PII/III processors, mainly to house a larger internal board with more cache memory. The Xeon processor is shown in Figure 3.53; the Xeon's SEC is shown in Figure 3.54.

Besides the larger package, the Xeon processors also include more L2 cache. They are available in three variations, with 512KB, 1MB, or 2MB of L2 cache. This cache is costly; the list price of the 2MB version is more than $2,000!

L2 Speed	Max. Temp. (C)	Voltage	Max. Power (W)	Process (Microns)	Transistors	Package

CPUID = The internal ID returned by the CPUID instruction
ECC = Error correcting code

Figure 3.53 Pentium III Xeon processor. *Photograph used by permission of Intel Corporation.*

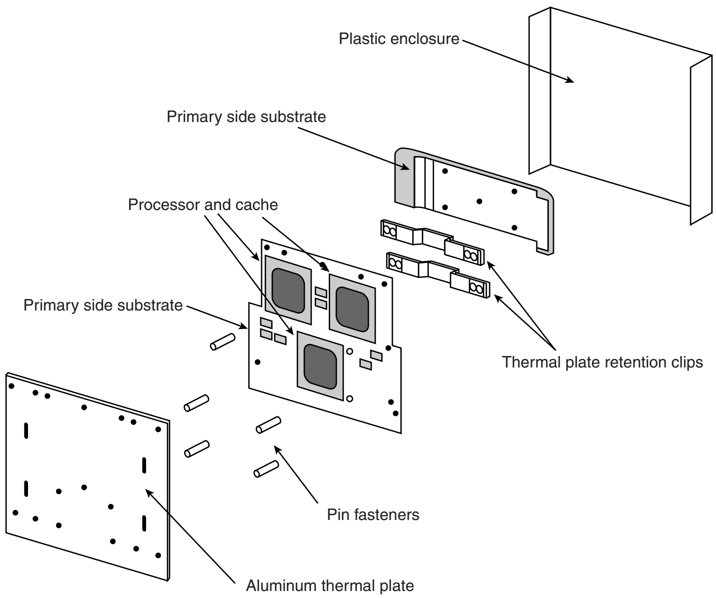

Figure 3.54 Xeon processor internal components.

Even more significant than the size of the cache is its speed. All the cache in the Xeon processors run at the full-core speed. This is difficult to do considering that the cache chips are separate chips on the board; up until recently they were not integrated into the processor die. The original Pentium II Xeon processors had 7.5 million transistors in the main processor die, whereas the later Pentium III Xeon came with 9.5 million. When the Pentium III versions with on-die cache were released, the transistor count went up to 28.1 million transistors in the 256KB cache version, 84 million transistors in the 1MB cache version, and a whopping 140 million transistors in the latest 2MB cache version, setting an industry record. The high transistor counts are due to the on-die L2 cache, which is very transistor intensive. The L2 cache in all Xeon processors has a full 64GB RAM address range and supports ECC.

Note that the Slot 2 Xeon processors do not replace the Slot 1 processors. Xeon processors for Slot 2 are targeted at the mid-range to high-end server and workstation market segments, offering larger, full-speed L2 caches and four-way multiprocessor support. Pentium III processors for Slot 1 will continue to be the processor used in the business and home desktop market segments, and for entry-level servers and workstations (single- and dual-processor systems).

Other Sixth-Generation Processors

Besides Intel, many other manufacturers are now making P6-type processors, but often with a difference. Most of them are designed to interface with P5 class motherboards and for the lower-end markets. AMD has recently offered up the Athlon and Duron processors, which are true sixth-generation designs using their own proprietary connections to the system.

This section examines the various sixth-generation processors from manufacturers other than Intel.

NexGen Nx586

NexGen was founded by Thampy Thomas, who hired some of the people formerly involved with the 486 and Pentium processors at Intel. At NexGen, developers created the Nx586, a processor that was functionally the same as the Pentium but not pin compatible. As such, it was always supplied with a motherboard; in fact, it was usually soldered in. NexGen did not manufacture the chips or the motherboards they came in; for that it hired IBM Microelectronics. Later NexGen was bought by AMD, right before it was ready to introduce the Nx686—a greatly improved design done by Greg Favor and a true competitor for the Pentium. AMD took the Nx686 design and combined it with a Pentium electrical interface to create a drop-in Pentium-compatible chip called the K6, which actually outperformed the original from Intel.

The Nx586 had all the standard fifth-generation processor features, such as superscalar execution with two internal pipelines and a high-performance integral L1 cache with separate code and data caches. One advantage is that the Nx586 includes separate 16KB instruction and 16KB data caches compared to 8KB each for the Pentium. These caches keep key instruction and data close to the processing engines to increase overall system performance.

The Nx586 also includes branch prediction capabilities, which are one of the hallmarks of a sixth-generation processor. Branch prediction means the processor has internal functions to predict program flow to optimize the instruction execution.

The Nx586 processor also featured a RISC core. A translation unit dynamically translates x86 instructions into RISC86 instructions. These RISC86 instructions were designed specifically with direct support for the x86 architecture while obeying RISC performance principles. They are thus simpler and easier to execute than the complex x86 instructions. This type of capability is another feature normally found only in P6 class processors.

The Nx586 was discontinued after the merger with AMD, which then took the design for the successor Nx686 and released it as the AMD-K6.

AMD-K6 Series

The AMD-K6 processor is a high-performance sixth-generation processor that is physically installable in a P5 (Pentium) motherboard. It essentially was designed for AMD by NexGen and was first known as the Nx686. The NexGen version never appeared because it was purchased by AMD before the chip was due to be released. The AMD-K6 delivers performance levels somewhere between the Pentium and Pentium II processor as a result of its unique hybrid design. Because it is designed to install in Socket 7, which is a fifth-generation processor socket and motherboard design, it can't quite perform as a true sixth-generation chip because the Socket 7 architecture severely limits cache and memory performance. However, with this processor, AMD gave Intel a lot of competition in the low- to mid-range market, where the Pentium was still popular.

The K6 processor contains an industry-standard, high-performance implementation of the new multimedia instruction set, enabling a high level of multimedia performance. The K6-2 introduced an upgrade to MMX that AMD calls 3DNow, which adds even more graphics and sound instructions. AMD designed the K6 processor to fit the low-cost, high-volume Socket 7 infrastructure. This enables PC manufacturers and resellers to speed time to market and deliver systems with an easy upgrade path for the future. AMD's state-of-the-art manufacturing facility in Austin, Texas (Fab 25) makes the AMD-K6 series processors. Initially, it used AMD's 0.35-micron, five-metal layer process technology; newer variations use the 0.25-micron processor to increase production quantities because of reduced die size, as well as to decrease power consumption.

AMD-K6 processor technical features include

- Sixth-generation internal design, fifth-generation external interface
- Internal RISC core, translates x86 to RISC instructions
- Superscalar parallel execution units (seven)

- Dynamic execution
- Branch prediction
- Speculative execution
- Large 64KB L1 cache (32KB instruction cache plus 32KB write-back dual-ported data cache)
- Built-in floating-point unit
- Industry-standard MMX instruction support
- System Management Mode
- Ceramic pin grid array (CPGA) Socket 7 design
- Manufactured using a 0.35-micron and a 0.25-micron, five-layer design

The K6-2 adds

- Higher clock speeds
- Higher bus speeds of up to 100MHz (Super7 motherboards)
- 3DNow; 21 new graphics and sound processing instructions

The K6-3 adds

- 256KB of on-die full-core speed L2 cache

The addition of the full-speed L2 cache in the K6-3 is significant. It brings the K6 series to a level where it can fully compete with the Intel Celeron and Pentium II processors. The 3DNow capability added in the K6-2/3 is also being exploited by newer graphics programs, making these processors ideal for lower-cost gaming systems.

The AMD-K6 processor architecture is fully x86 binary code compatible, which means it runs all Intel software, including MMX instructions. To make up for the lower L2 cache performance of the Socket 7 design, AMD has beefed up the internal L1 cache to 64KB total, twice the size of the Pentium II or III. This, plus the dynamic execution capability, enables the K6 to outperform the Pentium and come close to the Pentium II in performance for a given clock rate. The K6-3 is even better with the addition of full-core speed L2 cache.

Both the AMD-K5 and AMD-K6 processors are Socket 7 bus compatible. However, certain modifications might be necessary for proper voltage setting and BIOS revisions. To ensure reliable operation of the AMD-K6 processor, the motherboard must meet specific voltage requirements.

The AMD processors have specific voltage requirements. Most older split-voltage motherboards default to 2.8v Core/3.3v I/O, which is below specification for the AMD-K6 and could cause erratic operation. To work properly, the motherboard must have Socket 7 with a dual-plane voltage regulator supplying 2.9v or 3.2v (233MHz) to the CPU core voltage (Vcc2) and 3.3v for the I/O (Vcc3). The voltage regulator must be capable of supplying up to 7.5A (9.5A for the 233MHz) to the processor. When used with a 200MHz or slower processor, the voltage regulator must maintain the core voltage within 145 mV of nominal (2.9v+/-145 mV). When used with a 233MHz processor, the voltage regulator must maintain the core voltage within 100 mV of nominal (3.2v+/-100 mV).

If the motherboard has a poorly designed voltage regulator that cannot maintain this performance, unreliable operation can result. If the CPU voltage exceeds the absolute maximum voltage range, the processor can be permanently damaged. Also note that the K6 can run hot. Make sure your heatsink is securely fitted to the processor and that the thermally conductive grease or pad is properly applied.

The motherboard must have an AMD-K6 processor-ready BIOS with support for the K6 built in. Award has that support in its March 1, 1997 or later BIOS; AMI had K6 support in any of its BIOS with CPU Module 3.31 or later; and Phoenix supports the K6 in version 4.0, release 6.0, or release 5.1 with build dates of 4/7/97 or later.

Because these specifications can be fairly complicated, AMD keeps a list of motherboards that have been verified to work with the AMD-K6 processor on its Web site. All the motherboards on that list have been tested to work properly with the AMD-K6. So, unless these requirements can be verified elsewhere, it is recommended that you use only a motherboard from that list with the AMD-K6 processor.

The multiplier, bus speed, and voltage settings for the K6 are shown in Table 3.34. You can identify which AMD-K6 you have by looking at the markings on this chip, as shown in Figure 3.55.

Table 3.34 AMD-K6 Processor Speeds and Voltages

Processor	Core Speed	Clock Multiplier	Bus Speed	Core Voltage	I/O Voltage
K6-3	450MHz	4.5x	100MHz	2.4v	3.3v
K6-3	400MHz	4x	100MHz	2.4v	3.3v
K6-2	475MHz	5x	95MHz	2.4v	3.3v
K6-2	450MHz	4.5x	100MHz	2.4v	3.3v
K6-2	400MHz	4x	100MHz	2.2v	3.3v
K6-2	380MHz	4x	95MHz	2.2v	3.3v
K6-2	366MHz	5.5x	66MHz	2.2v	3.3v
K6-2	350MHz	3.5x	100MHz	2.2v	3.3v
K6-2	333MHz	3.5x	95MHz	2.2v	3.3v
K6-2	333MHz	5.0x	66MHz	2.2v	3.3v
K6-2	300MHz	3x	100MHz	2.2v	3.3v
K6-2	300MHz	4.5x	66MHz	2.2v	3.3v
K6-2	266MHz	4x	66MHz	2.2v	3.3v
K6	300MHz	4.5x	66MHz	2.2v	3.45v
K6	266MHz	4x	66MHz	2.2v	3.3v
K6	233MHz	3.5x	66MHz	3.2v	3.3v
K6	200MHz	3x	66MHz	2.9v	3.3v
K6	166MHz	2.5x	66MHz	2.9v	3.3v

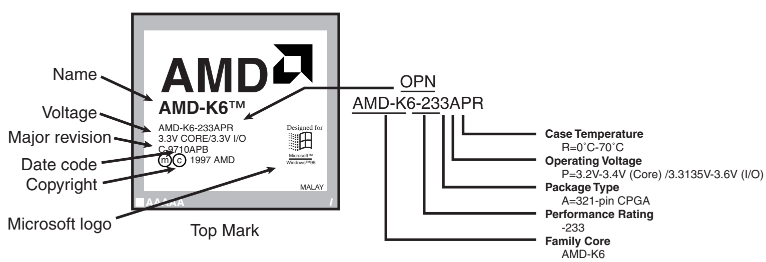

Figure 3.55 AMD-K6 processor markings.

Older motherboards achieve the 3.5x setting by setting jumpers for 1.5x. The 1.5x setting for older motherboards equates to a 3.5x setting for the AMD-K6 and newer Intel parts. To get the 4x and higher setting requires a motherboard that controls three BF pins, including BF2. Older motherboards can control only two BF pins. The settings for the multipliers are shown in Table 3.35.

Table 3.35 AMD-K6 Multiplier Settings

Multiplier Setting	BF0	BF1	BF2
2.5x	Low	Low	High
3x	High	Low	High
3.5x	High	High	High
4x	Low	High	Low
4.5x	Low	Low	Low
5x	High	Low	Low
5.5x	High	High	Low

These settings usually are controlled by jumpers on the motherboard. Consult your motherboard documentation to see where they are and how to set them for the proper multiplier and bus speed settings.

Unlike Cyrix and some of the other Intel competitors, AMD is a manufacturer and a designer. Therefore, it designs and builds its chips in its own fabs. Similar to Intel, AMD has migrated to 0.25-micron process technology and beyond. The original K6 has 8.8 million transistors and is built on a 0.35-micron, five-layer process. The die is 12.7mm on each side, or about 162 square mm. The K6-3 uses a 0.25-micron process and now incorporates 21.3 million transistors on a die only 10.9mm on each side, or about 118 square mm. Further process improvements will enable even more transistors, smaller die, higher yields, and greater numbers of processors. AMD has recently won contracts with several high-end system suppliers, which gives it an edge on the other Intel competitors.

Because of its performance and compatibility with the Socket 7 interface, the K6 series is often looked at as an excellent processor upgrade for motherboards currently using older Pentium or Pentium MMX processors. Although they do work in Socket 7, the AMD-K6 processors have different voltage and bus speed requirements from the Intel processors. Before attempting any upgrades, you should check the board documentation or contact the manufacturer to see whether your board meets the necessary requirements. In some cases, a BIOS upgrade also is necessary.

AMD Athlon

The Athlon is AMD's successor to the K6 series (refer to Figure 3.55). The Athlon is a whole new chip from the ground up and does not interface via the Socket 7 or Super7 sockets like its previous chips. In the initial Athlon versions, AMD used a cartridge design, called Slot A, almost exactly like that of the Intel Pentium II and III. This was due to the fact that the original Athlons used 512KB of external L2 cache, which was mounted on the processor cartridge board. The external cache ran at one-half core, two-fifths core, or one-third core depending on which speed processor you had. In June 2000, AMD introduced a revised version of the Athlon (codenamed Thunderbird) that incorporates 256KB of L2 cache directly on the processor die. This on-die cache runs at full-core speed and eliminates a bottleneck in the original Athlon systems. Along with the change to on-die L2 cache, the Athlon was also introduced in a PGA or chip Socket A version, which is replacing the Slot A cartridge version.

Although the Slot A cartridge looks a lot like the Intel Slot 1, and the Socket A looks like Intel's Socket 370, the pinouts are completely different, and the AMD chips do not work in the same motherboards as the Intel chips. This was by design because AMD was looking for ways to improve its chip architecture and distance itself from Intel. Special blocked pins in either socket or slot design prevent accidentally installing the chip in the wrong orientation or wrong slot. Figure 3.56 shows the Athlon in the Slot A cartridge. Figure 3.57 shows the Athlon in the PGA package (Socket A).

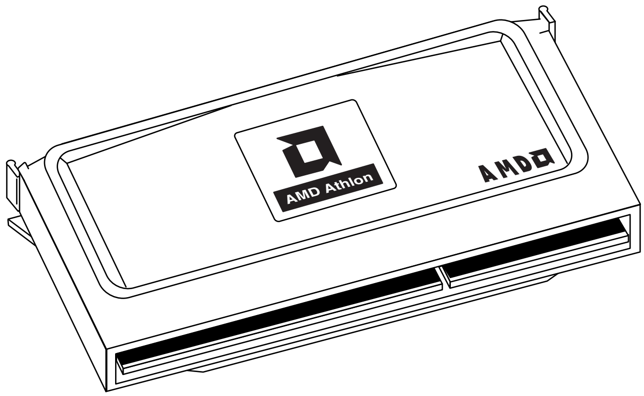

Figure 3.56 AMD Athlon processor for Slot A (cartridge form factor).

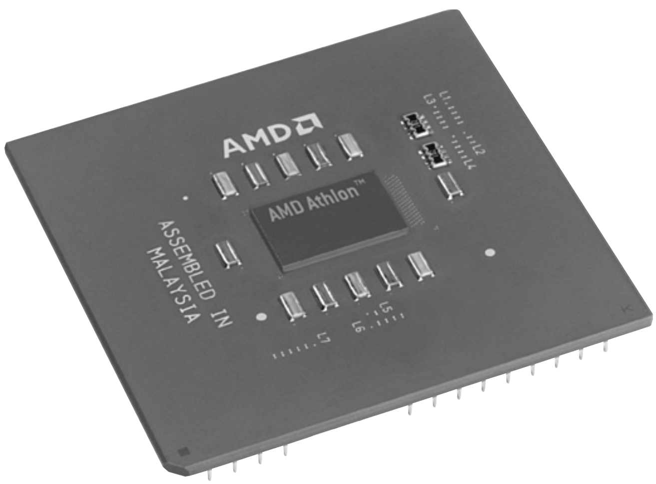

Figure 3.57 AMD Athlon processor for Socket A (PGA form factor).

The Athlon is available in speeds from 550MHz up to 1GHz and beyond and uses a 200MHz or 266MHz processor (front-side) bus called the EV6 to connect to the motherboard North Bridge chip as well as other processors. Licensed from Digital Equipment, the EV6 bus is the same as that used for the Alpha 21264 processor, now owned by Compaq. The EV6 bus uses a clock speed of 100MHz or 133MHz but double-clocks the data, transferring data twice per cycle, for a cycling speed of 200MHz or 266MHz. Because the bus is 8 bytes (64 bits) wide, this results in a throughput of 8 bytes times

200MHz/266MHz, which amounts to 1.6GB/sec or 2.1GB/sec. This bus is ideal for supporting PC1600 or PC2100 DDR memory, which also runs at those speeds. The AMD bus design eliminates a potential bottleneck between the chipset and processor and enables more efficient transfers compared to other processors. The use of the EV6 bus is one of the primary reasons the Athlon and Duron chips perform so well.

The Athlon has a very large 128KB of L1 cache on the processor die and one-half, two-fifths, or one-third core speed 512KB L2 cache in the cartridge in the older versions, or 256KB of full-core speed cache in the later ones. All PGA socket A versions have the full-speed cache. The Athlon also has support for MMX and the Enhanced 3DNow instructions, which are 45 new instructions designed to support graphics and sound processing. 3DNow is very similar to Intel's SSE in design and intent, but the

specific instructions are different and require software support. Fortunately, most companies producing graphics software have decided to support the 3DNow instructions along with the Intel SSE instructions, with only a few exceptions.

The initial production of the Athlon used 0.25-micron technology, with newer and faster versions being made on a 0.18-micron process. The latest versions are even built using copper metal technology, a first in the PC processor business. Eventually all other processors will follow because copper connects allow for lower power consumption and faster operation.

Table 3.36 shows detailed information on the Slot A version of the Athlon processor.

Table 3.37 shows information on the PGA or Socket A version of the AMD Athlon processor.

AMD is taking on Intel full force in the high-end market with the Athlon. It beat Intel to the 1GHz mark by introducing its 1GHz Athlon two days before Intel introduced the 1GHz Pentium III, and in most benchmarks the AMD Athlon compares as equal if not superior to the Intel Pentium III.

AMD Duron

The AMD Duron processor (codenamed Spitfire) was announced in June 2000 and is a derivative of the AMD Athlon processor in the same fashion as the Celeron is a derivative of the Pentium II and III (see Figure 3.58). Basically, the Duron is an Athlon with less L2 cache; all other capabilities are essentially the same. It is designed to be a lower-cost version with less cache but only slightly less performance. In keeping with the low-cost theme, Duron contains 64KB on-die L2 cache and is designed for Socket A, a socket version of the Athlon Slot A. With the high-value design the Duron processor is expected to compete in the sub $600 PC market against the Celeron, just as the Athlon is designed to compete in the higher-end Pentium III market.

Because the Duron processor is derived from the Athlon core, it includes the Athlon 200MHz front-side system bus (interface to the chipset) as well as enhanced 3DNow instructions.

Table 3.38 shows information on the PGA or Socket A version of the AMD Athlon processor.

Cyrix/IBM 6x86 (M1) and 6x86MX (MII)

The Cyrix 6x86 processor family consists of the now-discontinued 6x86 and the newer 6x86MX processors. They are similar to the AMD-K5 and K6 in that they offer sixth-generation internal designs in a fifth-generation P5 Pentium-compatible Socket 7 exterior.

The Cyrix 6x86 and 6x86MX (renamed MII) processors incorporate two optimized superpipelined integer units and an on-chip floating-point unit. These processors include the dynamic execution capability that is the hallmark of a sixth-generation CPU design. This includes branch prediction and speculative execution.

The 6x86MX/MII processor is compatible with MMX technology to run MMX games and multimedia software. With its enhanced memory-management unit, a 64KB internal cache, and other advanced architectural features, the 6x86MX processor achieves higher performance and offers better value than competitive processors.

Features and benefits of the 6x86 processors include

- *Superscalar architecture.* Two pipelines to execute multiple instructions in parallel
- *Branch prediction.* Predicts with high accuracy the next instructions needed
- *Speculative execution.* Enables the pipelines to continuously execute instructions following a branch without stalling the pipelines
- *Out-of-order completion.* Lets the faster instruction exit the pipeline out of order, saving processing time without disrupting program flow

The 6x86 incorporates two caches: a 16KB dual-ported unified cache and a 256-byte instruction line cache. The unified cache is supplemented with a small quarter-K–size high-speed, fully associative instruction line cache. The improved 6x86MX design quadruples the internal cache size to 64KB, which significantly improves performance.

The 6x86MX also includes the 57 MMX instructions that speed up the processing of certain computing-intensive loops found in multimedia and communication applications.

All 6x86 processors feature support for SMM. This provides an interrupt that can be used for system power management or software transparent emulation of I/O peripherals. Additionally, the 6x86 supports a hardware interface that enables the CPU to be placed into a low-power suspend mode.

Voltage	Max. Current (A)	Max. Power (W)	Process (Microns)	Transistors
1.6V	15.8A	25.3W	0.18	25M
1.6V	17.1A	27.4W	0.18	25M
1.6V	18.4A	29.4W	0.18	25M
1.6V	19.6A	31.4W	0.18	25M
1.6V	20.9A	33.4W	0.18	25M
1.6V	22.1A	35.4W	0.18	25M
1.6V	23.4A	37.4W	0.18	25M
1.6V	24.7A	39.5W	0.18	25M

The 6x86 is compatible with x86 software and all popular x86 operating systems, including Windows 95/98/Me, Windows NT/2000, OS/2, DOS, Solaris, and Unix. Additionally, the 6x86 processor has been certified Windows 95 compatible by Microsoft.

As with the AMD-K6, there are some unique motherboard requirements for the 6x86 processors. Cyrix maintains a list of recommended motherboards on its Web site that should be consulted if you are considering installing one of these chips in a board.

When installing or configuring a system with the 6x86 processors, you have to set the correct motherboard bus speed and multiplier settings. The Cyrix processors are numbered based on a P-Rating scale, which is not the same as the true megahertz clock speed of the processor.

See the section "Cyrix P-Ratings," earlier in this chapter, for the correct and true speed settings for the Cyrix 6x86 processors.

Note that because of the use of the P-Rating system, the actual speed of the chip is not the same number at which it is advertised. For example, the 6x86MX-PR300 is not a 300MHz chip; it actually runs at only 263MHz or 266MHz, depending on exactly how the motherboard bus speed and CPU clock multipliers are set. Cyrix says it runs as fast as a 300MHz Pentium, hence the P-Rating. Personally, I wish it would label the chip at the correct speed and then say that it runs faster than a Pentium at the same speed.

To install the 6x86 processors in a motherboard, you also must set the correct voltage. Normally, the markings on top of the chip indicate which voltage setting is appropriate. Various versions of the 6x86 run at 3.52v (use VRE setting), 3.3v (VR setting), or 2.8v (MMX) settings. The MMX versions use the standard split-plane 2.8v core 3.3v I/O settings.

Intel Pentium 4 (Seventh-Generation) Processors

The Pentium 4 was introduced in November 2000 and represents a new generation in processors (see Figure 3.59). If this one had a number instead of a name, it might be called the 786 because it represents a generation beyond the previous 686 class processors. The processor die is shown in Figure 3.60.

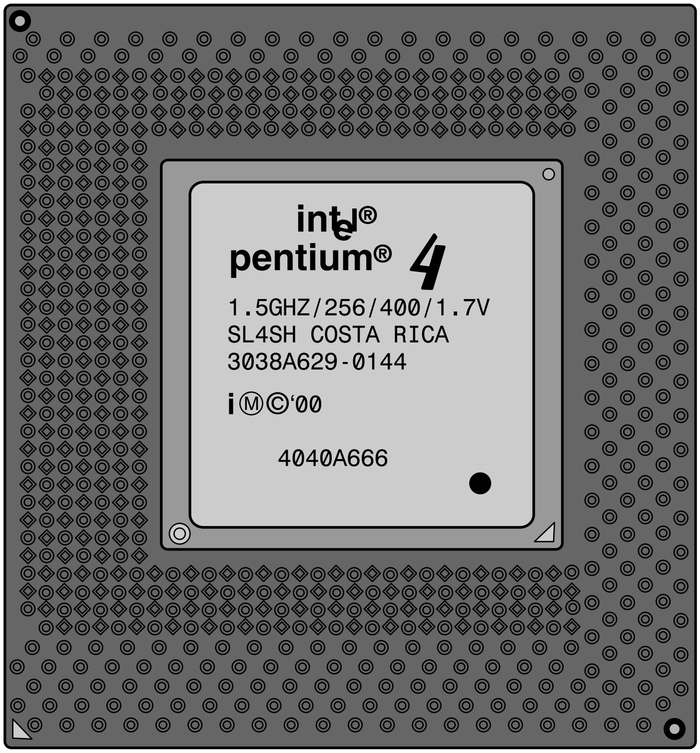

Figure 3.59 Pentium 4 processor.

The main technical details for the Pentium 4 include

- Speeds range from 1.3GHz to 1.7GHz and beyond.
- 42 million transistors, 0.18-micron process.
- Software compatible with previous Intel 32-bit processors.
- Processor (front-side) bus runs at 400MHz.
- Arithmetic logic units (ALUs) run at twice the processor core frequency.
- Hyper-pipelined (20-stage) technology.
- Very deep out-of-order instruction execution.
- Enhanced branch prediction.
- 20KB L1 cache (12KB L1 execution trace cache plus 8KB L1 data cache).
- 256KB on-die, full-core speed 128-bit L2 cache with eight-way associativity.
- L2 cache can handle up to 4GB RAM and supports ECC.
- SSE2—144 new SSE2 instructions.
- Enhanced floating-point unit.
- Multiple low-power states.

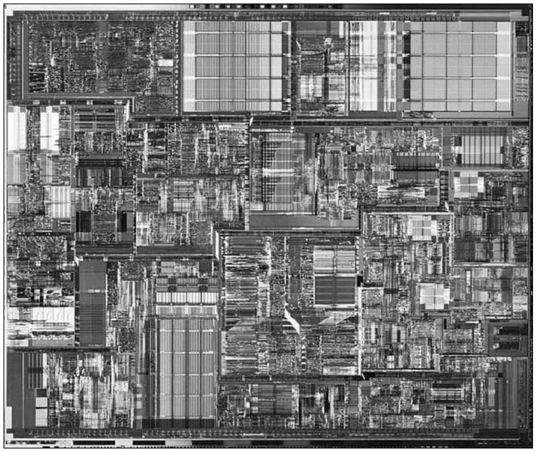

Figure 3.60 Pentium 4 die (0.18-micron process, 42 million transistors). *Photograph used by permission of Intel Corporation.*

Intel has abandoned roman numerals for a standard Arabic numeral 4 designation. Internally, the Pentium 4 introduces a new architecture Intel calls NetBurst microarchitecture, which includes hyper-pipelined technology, a rapid execution engine, a 400MHz system bus, and an execution trace cache. The hyper-pipelined technology doubles the instruction pipeline depth as compared to the Pentium III, meaning more and smaller steps are required to execute instructions. However, it also enables much higher clock speeds to be more easily attained. The rapid execution engine enables the two integer arithmetic logic units (ALUs) to run at twice the processor core frequency, which means instructions can execute in 1/2 a clock cycle. The 400MHz system bus is a quad-pumped bus running off a 100MHz system clock transferring data four times per clock cycle. The execution trace cache is a high-performance Level 1 cache that stores approximately 12k decoded micro-operations. This removes the instruction decoder from the main execution pipeline, increasing performance.

Of these the high-speed processor bus is most notable. Technically speaking, the processor bus is a 100MHz quad-pumped bus that transfers four times per cycle (4x), for a 400MHz effective rate. Because the bus is 64 bits (8 bytes) wide, this results in a throughput rate of 3,200MB/sec. This matches the speed of the dual-channel RDRAM, which is 1,600MB/sec per channel, or 3,200MB/sec total. The use of dual-channel RDRAM means that RIMMs must be added in matched pairs. Dual banks of PC1600 DDR would also match this bandwidth, and that might be an option in the future as new chipsets arrive.

In the new 20-stage pipelined internal architecture, individual instructions are broken down into many more sub-stages, making this almost like a RISC processor. Unfortunately, this can add to the number of cycles taken to execute instructions if they are not optimized for this processor. Early benchmarks running existing software showed that existing Pentium III or AMD Athlon processors could easily keep pace with or even exceed the Pentium 4 in specific tasks; however, this is changing now that applications are being recompiled to work smoothly with the Pentium 4's deep pipelined architecture.

The Intel Pentium 4 also introduces a new CPU socket, more stringent memory configuration, and even new power supply and case requirements.

The Pentium 4 is the first Intel CPU to use Socket 423, which has 423 pins in a 39x39 SPGA arrangement. Voltage selection is made via an automatic voltage regulator module installed on the motherboard and wired to the socket.

Memory Requirements

Although current Pentium 4–based motherboards use the same Rambus RDRAM RIMM modules introduced for use with some of the chipsets used in Pentium III motherboards, the dual RDRAM channels the Pentium 4 uses require you to install pairs of identical modules (called RIMMs). If your Pentium III motherboard uses SDRAM, you must get entirely new RDRAM memory for any P4 upgrade. If your Pentium III board uses RIMMs, but is not using two identical (same speed/same size) RIMM modules, you must buy additional RIMMs to match the modules you're currently using to make identical pairs to use on your new Pentium 4 motherboard. What if you're using three RIMM modules on your current motherboard? If two are identical, you can use them on your new motherboard; if you want to use the third one, you must buy a matching module because you must populate your Pentium 4 motherboard with either one or two pairs of RIMMs. Both pairs of memory must be the same speed, but need not be the same size.

Whereas most initial Pentium 4 motherboard chipsets supported only RDRAM memory, newer chipsets are either available or becoming available that support more standard memory, such as DDR SDRAM.

Power Supply Issues

The Pentium 4 requires a lot of electrical power, and because of this, most Pentium 4 motherboards use a new design voltage regulator module that is powered from 12v instead of 3.3v or 5v, as with previous designs. By using the 12v power, more 3.3v and 5v power is available to run the rest of the system, and the overall current draw is greatly reduced with the higher voltage as a source. PC power supplies generate a more than adequate supply of 12v power, but the ATX motherboard and power supply design originally allotted only one pin for 12v power (each pin is rated for only 6 amps), so additional 12v lines were necessary to carry this power to the motherboard.

The fix appears in the form of a third power connector, called the ATX12V connector. This new connector is used in addition to the standard 20-pin ATX power supply connector and 6-pin auxiliary (3.3/5v) connector. Fortunately, the power supply itself won't need a redesign; there is more than enough 12v power available from the drive connectors. To utilize this, companies such as PC Power and Cooling sell an inexpensive ($8) adapter that converts a standard Molex-type drive power connector to the ATX12V connector. Normally, a 300-watt (the minimum recommended) or larger power supply has more than adequate levels of 12v power for both the drives and the ATX12V connector.

If your power supply is less than the 300-watt minimum recommended, you need to purchase a replacement; some vendors now sell an off-the-shelf ATX12V ready model or one that uses the adapter mentioned previously.

The various Pentium 4 versions, including thermal and power specifications, are shown in Table 3.39.

Table 3.39 Pentium 4 Processor Information

Cooling a high wattage unit such as the Pentium 4 requires a large active heatsink. These heavy (sometimes more than 1 lb.) heatsinks can damage a CPU or destroy a motherboard when subjected to vibration or shock, especially during shipping. To prevent this, Intel's specifications for the Pentium 4 add four standoffs to the ATX chassis design flanking the Socket 423 to support the heatsink retention brackets. These standoffs enable the chassis to support the weight of the heatsink instead of depending on the motherboard, as with older designs.

The heatsink retention mechanism consists of two brackets screwed to new chassis standoffs through the motherboard, and then two clips that attach the heatsink to the brackets. The brackets and clips are to be included with the motherboard, and the standoffs with screws are to be included with the chassis. For compatibility between chassis and motherboards, Intel is recommending that all Pentium 4 motherboards use the same location for the CPU: near the right edge of the motherboard. This enables case designers to supply a single modified ATX case design for all Pentium 4 motherboards. Even so, vendors can also use other means to reinforce the CPU location without requiring a direct chassis attachment. For example, Asus' P4T motherboard ships with a metal reinforcing plate to enable off-the-shelf ATX cases to work with the motherboard.

A future version of the Pentium 4 (codenamed Northwood) will be built using a 0.13-micron process and will use a different socket (called Socket 478) from the initial Pentium 4. This would be similar to how Intel changed the original Pentium sockets early in their lifecycles. An upgrade to this newer version will require a new motherboard with Socket 478.

Itanium (Eighth-Generation) Processors

Introduced in May 2001, the Itanium is currently the highest-end processor from Intel, designed mainly for the server market. If Intel was still using numbers to designate its processors, Itanium might be called the 886 because it is the eighth-generation processor in the Intel family, and it represents the most significant processor architecture advancement since the 386.

Itanium is the first processor in Intel's IA-64 (Intel Architecture 64-bit) product family and incorporates innovative performance-enhancing architecture techniques, such as prediction and speculation.

Itanium

Intel's IA-64 product family is designed to expand the capabilities of the Intel architecture to address the high-performance server and workstation market segments.

As with previous new processor introductions, the Itanium is not designed to replace the Pentium 4 or III, at least not at first. It features an all-new design that is initially expensive and is found only in the highest-end systems such as file servers or workstations. Intel is already developing an even more advanced Itanium class processor, due to ship in 2002, which will be significantly faster than Itanium.

The Itanium technical details are as follows:

- Introduced at 733MHz and 800MHz speeds.
- Three levels of integrated cache:
  - 2MB or 4MB unified on-cartridge L3 cache running at full-core speed on an integrated 128-bit L3 cache bus
  - 96KB unified on-die L2 cache running at full-core speed
  - 32KB segmented (16KB instruction/16KB data) L1 cache
- 266MHz, 64-bit wide (plus 8 bits for ECC) CPU front-side bus with 2.1GB/sec bandwidth.
- 25 million transistors, with up to 300 million additional in the L3 cache.
- 16TB (terabytes) physical memory addressing (44-bit address bus).
- Full 32-bit instruction compatibility in hardware.
- EPIC (explicitly parallel instruction computing) technology, which enables up to 20 operations per cycle.
- Two integer and two memory units that can execute four instructions per clock.
- Two FMAC (floating-point multiply accumulate) units with 82-bit operands.
- Each FMAC unit is capable of executing two floating-point operations per clock.
- Two additional MMX units are capable of executing two single-precision FP operations each.
- A total of eight single-precision FP operations can be executed every cycle.
- 128 integer registers, 128 floating-point registers, 8 branch registers, 64 predicate registers.
- 3-inch×5-inch cartridge includes processor and 2MB or 4MB L3 cache.
- Dedicated cartridge power connector improves signal integrity.

Intel and Hewlett-Packard began jointly working on the Itanium processor in 1994. In October 1997, more than three years after they first disclosed their plan to work together on a new microprocessor architecture, Intel and HP officially announced some of the new processor's technical details.

Itanium is the first microprocessor based on the Intel architecture-64 (IA-64) specification. IA-64 is a completely different processor design, which will use Very Long Instruction Words (VLIW), instruction prediction, branch elimination, speculative loading, and other advanced processes for enhancing parallelism from program code. The new chip features elements of both CISC and RISC design.

Itanium incorporates a new architecture Intel calls explicitly parallel instruction computing (EPIC), which enables the processor to execute *parallel instructions*—several instructions at the same time. In the Itanium, three instructions can be encoded in one 128-bit word, so that each instruction has a few more bits than today's 32-bit instructions. The extra bits let the chip address more registers and tells the processor which instructions to execute in parallel. This approach simplifies the design of processors with many parallel-execution units and should let them run at higher clock rates. In other words, besides being capable of executing several instructions in parallel within the chip, the Itanium can be linked to other Itanium chips in a parallel processing environment.

Besides having new features and running a completely new 64-bit instruction set, Itanium features full backward compatibility with the current 32-bit Intel x86 software. In this way, Itanium supports 64-bit instructions while retaining full compatibility with today's 32-bit applications. Full backward compatibility means it will run all existing applications as well as any new 64-bit applications.

To use the IA-64 instructions, programs must be recompiled for the new instruction set. This is similar to what happened in 1985, when Intel introduced the 386, the first 32-bit PC processor. The 386 gave us a platform for an advanced 32-bit operating system that tapped this new power. To ensure immediate acceptance, the 386 and future 32-bit processors still ran 16-bit code. To take advantage of the 32-bit capability first found in the 386, new software would have to be written. Unfortunately, software evolves much more slowly than hardware. It took Microsoft a full 10 years after the 386 debuted to release Windows 95, the first mainstream 32-bit operating system for Intel processors.

That won't happen with the Itanium, which already has support from four operating systems, including Microsoft Windows (XP 64-bit Edition and 64-bit Windows Advanced Server Limited Edition 2002), Linux (from four distributor companies: Red Hat, SuSE, Caldera, and Turbo Linux), and two Unix versions (Hewlett-Packard's HP-UX 11i v 1.5 and IBM's AIX-5L).

Despite the immediate OS support, it will likely take several years before the mainstream software market shifts to 64-bit operating systems and software. The installed base of 32-bit processors is simply too great, and the backward-compatible 32-bit mode of the Itanium will enable it to run 32-bit software very well because 32-bit instructions are handled directly in the hardware rather than through software emulation.

Itanium is initially based on 0.18-micron technology; however, later versions will move to 0.13 micron, allowing for higher speeds and larger caches.

Itanium comes in a new package called the pin array cartridge (PAC). This cartridge includes L3 cache and plugs into a PAC418 (418-pin) socket on the motherboard and not a slot. The package is about the size of a standard index card, weighs about 6oz. (170g), and has an alloy metal on its base to dissipate the heat (see Figure 3.61). Itanium has clips on its sides, enabling four to be hung from a motherboard, both below and above.

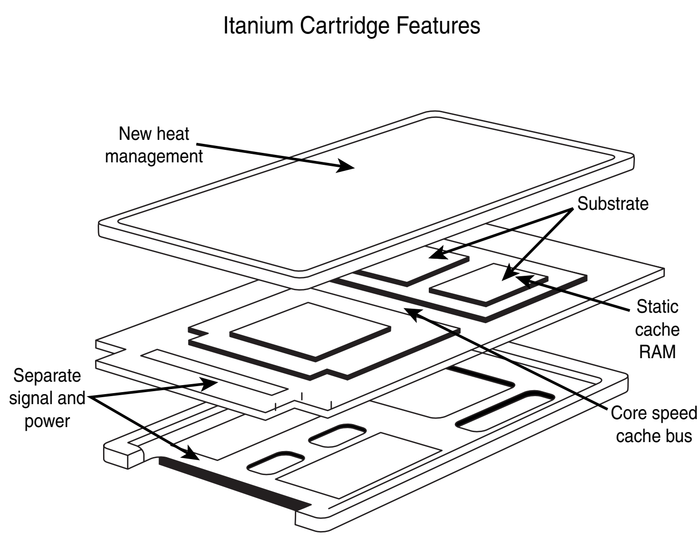

Figure 3.61 Itanium processor.

Itanium incorporates three levels of cache. The L1 cache is closely tied to the execution unit, and it is backed by on-die L2 cache. Finally, a 2MB or 4MB L3 cache is housed in separate chips contained within the cartridge.

Itanium will be followed in 2002 by a second IA-64 processor codenamed McKinley. McKinley will have larger on-die L2 cache and target clock speeds of more than 1.5GHz, offering more than twice the performance of Itanium. Following McKinley will be Madison, based on 0.13-micron technology. Both Itanium and McKinley are based on 0.18-micron technology.

Processor Upgrades

Since the 486, processor upgrades have been relatively easy for most systems. With the 486 and later processors, Intel designed in the capability to upgrade by designing standard sockets that would take a variety of processors. Thus, if you have a motherboard with Socket 3, you can put virtually any 486 processor in it; if you have a Socket 7 motherboard, it should be capable of accepting virtually any Pentium processor.

To maximize your motherboard, you can almost always upgrade to the fastest processor your particular board will support. Because of the varieties of processor sockets and slots—not to mention voltages, speeds, and other potential areas of incompatibility—you should consult with your motherboard manufacturer to see whether a higher-speed processor will work in your board. Usually, that can be determined by the type of socket or slot on the motherboard, but other things such as the voltage regulator and BIOS can be deciding factors as well.

For example, if your motherboard has a Pentium Socket 5, you can install a Pentium MMX 233MHz processor with a 2.8v voltage regulator adapter, or optionally an AMD-K6, also with a voltage regulator adapter. If you have Socket 7, your motherboard should be capable of supporting the lower-voltage Pentium MMX or AMD-K6 series directly without any adapters. The K6-2 and K6-3 are the fastest and best processors for Socket 7 motherboards.

Rather than purchasing processors and adapters separately, I usually recommend you purchase them together in a module from companies such as Kingston or Evergreen (see the Vendor List on the CD).

Upgrading the processor can, in some cases, double the performance of a system, such as if you were going from a Pentium 100 to an MMX 233. However, if you already have a Pentium 233, you already have the fastest processor that goes in that socket. In that case, you really should look into a complete motherboard change, which would let you upgrade to a Pentium III processor at the same time. If your chassis design is not proprietary and your system uses an industry-standard Baby-AT or ATX motherboard design, I normally recommend changing the motherboard and processor rather than trying to find an upgrade processor that will work with your existing board.

OverDrive Processors

Intel at one time offered special OverDrive processors for upgrading systems. Often these were repackaged versions of the standard processors, sometimes including necessary voltage regulators and fans. Unfortunately, they frequently were overpriced, even when compared against purchasing a complete new motherboard and processor. They have all been withdrawn, and Intel has not announced any new versions. I don't recommend the OverDrive processors unless the deal is too good to pass up.

Processor Benchmarks

People love to know how fast (or slow) their computers are. We have always been interested in speed; it is human nature. To help us with this quest, various benchmark test programs can be used to measure different aspects of processor and system performance. Although no single numerical measurement can completely describe the performance of a complex device such as a processor or a complete PC, benchmarks can be useful tools for comparing different components and systems.

However, the only truly accurate way to measure your system's performance is to test the system using the actual software applications you use. Although you think you might be testing one component of a system, often other parts of the system can have an effect. It is inaccurate to compare systems with different processors, for example, if they also have different amounts or types of memory, different hard disks, video cards, and so on. All these things and more will skew the test results.

Benchmarks can typically be divided into two types: component or system tests. *Component* benchmarks measure the performance of specific parts of a computer system, such as a processor, hard disk, video card, or CD-ROM drive, whereas *system* benchmarks typically measure the performance of the entire computer system running a given application or test suite.

Benchmarks are, at most, only one kind of information you can use during the upgrading or purchasing process. You are best served by testing the system using your own set of software operating systems and applications and in the configuration you will be running.

Several companies specialize in benchmark tests and software. The following table lists the company and the benchmarks they are known for. You can contact these companies via the information in the Vendor List on the CD.

Company	Benchmarks Published	Benchmark Type
Intel	iCOMP index 3.0	Processor/System
Business Applications	SYSmark	System
Performance Corporation	(BAPCo)	
Standard Performance	SPECint,	Processor Integer
Evaluation Corporation	SPECfp	Processor Floating
PointZiff-Davis		
Benchmark	CPUmark	Processor
Ziff-Davis Benchmark	Winstone	System
Ziff-Davis Benchmark	WinBench	System
Symantec Corporation	Norton SI32	Processor
Symantec Corporation	Norton SI32,	System

Processor Troubleshooting Techniques

Processors are normally very reliable. Most PC problems are with other devices, but if you suspect the processor, there are some steps you can take to troubleshoot it. The easiest thing to do is to replace the microprocessor with a known-good spare. If the problem goes away, the original processor is defective. If the problem persists, the problem is likely elsewhere.

Table 3.40 provides a general troubleshooting checklist for processor-related PC problems.

Table 3.40 Troubleshooting Processor-Related Problems

Problem Identification	Possible Cause	Resolution
System is dead, no cursor, no beeps, no fan.	Power cord failure.	Plug in or replace power cord. Power cords can fail even though they look fine.
	Power supply failure.	Replace the power supply. Use a known-good spare for testing.
	Motherboard failure.	Replace motherboard. Use a known-good spare for testing.
	Memory failure.	Remove all memory except 1 bank and retest. If the system still won't boot replace bank 1.

Table 3.40 Continued

Problem Identification	Possible Cause	Resolution
System is dead, no beeps, or locks up before POST begins.	All components either not installed or incorrectly installed.	Check all peripherals, especially memory and graphics adapter. Reseat all boards and socketed components.
System beeps on startup, fan is running, no cursor on screen.	Improperly seated or failing graphics adapter.	Reseat or replace graphics adapter. Use known-good spare for testing.
Locks up during or shortly after POST.	Poor heat dissipation.	Check CPU heatsink/fan; replace if necessary, use one with higher capacity.
	Improper voltage settings.	Set motherboard for proper core processor voltage.
	Wrong motherboard bus speed.	Set motherboard for proper speed.
	Wrong CPU clock multiplier.	Jumper motherboard for proper clock multiplier.
Improper CPU identification during POST.	Old BIOS.	Update BIOS from manufacturer.
	Board not configured properly.	Check manual and jumper board accordingly to proper bus and multiplier settings.
Operating system will not boot.	Poor heat dissipation.	Check CPU fan; replace if necessary, might need higher-capacity heatsink.
	Improper voltage settings.	Jumper motherboard for proper core voltage.
	Wrong motherboard bus speed.	Jumper motherboard for proper speed.
	Wrong CPU clock multiplier.	Jumper motherboard for proper clock multiplier.
	Applications will not install or run.	Improper drivers or incompatible hardware; update drivers and check for compatibility issues.
System appears to work, but no video is displayed.	Monitor turned off or failed.	Check monitor and power to monitor. Replace with known-good spare for testing.

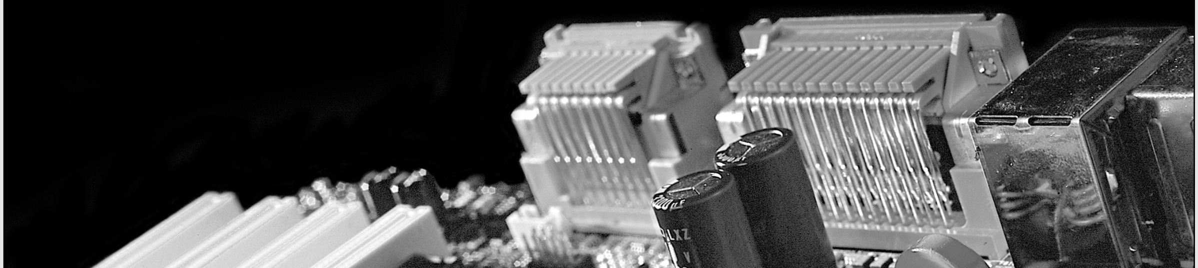
If during the POST the processor is not identified correctly, your motherboard settings might be incorrect or your BIOS might need to be updated. Check that the motherboard is jumpered or configured correctly for the processor that you have, and make sure you have the latest BIOS for your motherboard.

If the system seems to run erratically after it warms up, try setting the processor to a lower speed setting. If the problem goes away, the processor might be defective or overclocked.

Many hardware problems are really software problems in disguise. Be sure you have the latest BIOS for your motherboard, as well as the latest drivers for all your peripherals. Also, it helps to use the latest version of your given operating system because there usually will be fewer problems.

CHAPTER 4

Motherboards and Buses



Motherboard Form Factors

Without a doubt, the most important component in a PC system is the main board or motherboard. Some companies refer to the motherboard as a system board or planar. The terms *motherboard*, *main board*, *system board*, and *planar* are interchangeable. This chapter examines the various types of motherboards available and those components usually contained on the motherboard and motherboard interface connectors.

Several common form factors are used for PC motherboards. The *form factor* refers to the physical dimensions and size of the board and dictates what type of case the board will fit into. Some are true standards (meaning that all boards with that form factor are interchangeable), whereas others are not standardized enough to allow for true interchangeability. Unfortunately, these nonstandard form factors preclude any easy upgrade, which generally means they should be avoided. The more commonly known PC motherboard form factors include the following:

Obsolete Form Factors

- Baby-AT
- Full-size AT
- LPX (semiproprietary)

Modern Form Factors

- ATX
- Micro-ATX
- Flex-ATX
- NLX
- WTX (no longer in production)

All Others

- Proprietary Designs (certain Compaq, Packard Bell, Hewlett-Packard, notebook/portable systems, and so on)

Motherboards have evolved over the years from the original Baby-AT form factor boards used in the original IBM PC and XT to the current ATX and NLX boards used in most full-size desktop and tower systems. ATX has a number of variants, including Micro-ATX (which is a smaller version of the ATX form factor used in the smaller systems) and Flex-ATX (an even smaller version for the lowest-cost home PCs). NLX is designed for corporate desktop–type systems; WTX was designed for workstations and medium-duty servers, but never became popular. Table 4.1 shows the modern industry-standard form factors and their recommended uses.

Table 4.1 Industry-Standard Motherboard Form Factors

Form Factor	Use
ATX	Standard desktop, mini-tower, and full-tower systems; most common form factor today; most flexible design for power users, enthusiasts, low-end servers/workstations, higher-end home systems; ATX boards support up to seven expansion slots
Mini-ATX	A slightly smaller version of ATX that fits into the same case as ATX. Many so-called ATX motherboards are actually Mini-ATX motherboards; Mini-ATX boards support up to six expansion slots
Micro-ATX	Midrange desktop or mini-tower systems
Flex-ATX	Least expensive or low-end small desktop or mini-tower systems, entertainment or appliance systems
NLX	Corporate desktop or mini-tower systems; fast and easy serviceability
WTX	Mid- to high-end workstations, servers (withdrawn)

Although the Baby-AT, Full-size AT, and LPX boards were once popular, they have all but been replaced by more modern and interchangeable form factors. The modern form factors are true standards, which guarantees improved interchangeability within each type. This means that ATX boards will interchange with other ATX boards, NLX with other NLX, and so on. The additional features found on these boards as compared to the obsolete form factors, combined with true interchangeability, has made the migration to these newer form factors quick and easy. Today I recommend purchasing only systems with one of the modern industry-standard form factors.

Anything that does not fit into one of the industry-standard form factors is considered proprietary. Unless there are special circumstances, I do not recommend purchasing systems with proprietary board designs. They will be virtually impossible to upgrade and very expensive to repair later because the motherboard, case, and often power supply will not be interchangeable with other models. I call proprietary form factor systems "disposable" PCs because that's what you must normally do with them when they are too slow or need repair out of warranty.

Caution

"Disposable" PCs might be more common than ever. Some estimate that as much as 60% of all PCs sold today are disposable models, not so much because of the motherboards used (Flex or Micro-ATX motherboards are frequently used today instead of the semiproprietary LPX models previously favored) but because of the tiny SFX power supplies and cramped micro-tower cases that are favored on most retail-market PCs today. Although low-cost PCs using small chassis and power supplies are theoretically more upgradable than past disposable type systems, you'll still hit the wall over time if you need more than three expansion slots or want to use more than two or three internal drives. Because mini-tower systems are so cramped and limited, I consider them to be almost as disposable as the LPX systems they have largely replaced.

You also need to watch out for systems that only appear to meet industry standards, such as Dell computer models built from September 1998 to the present. These computers use a rewired version of the ATX power supply and motherboard power connectors, which makes both components completely incompatible with standard motherboards and power supplies. If you want to upgrade the power supply, you must use a special Dell-compatible power supply. And if you want to upgrade the motherboard, you must buy a standard power supply to match.

If you want to have a truly upgradable system, insist on a system that uses Micro-ATX or full-ATX motherboards in a mid-tower or larger case with at least five drive bays.

The following sections detail each of the standard form factors.

Baby-AT

The first popular PC motherboard was, of course, the original IBM PC released in 1981. Figure 4.1 shows how this board looked. IBM followed the PC with the XT motherboard in 1983, which had the same basic shape as the PC board but had eight slots instead of five. Also, the slots were spaced 0.8 inch apart instead of 1 inch apart as in the PC (see Figure 4.2). The XT also eliminated the weird cassette port in the back, which was supposed to be used to save BASIC programs on cassette tape instead of the much more expensive (at the time) floppy drive.

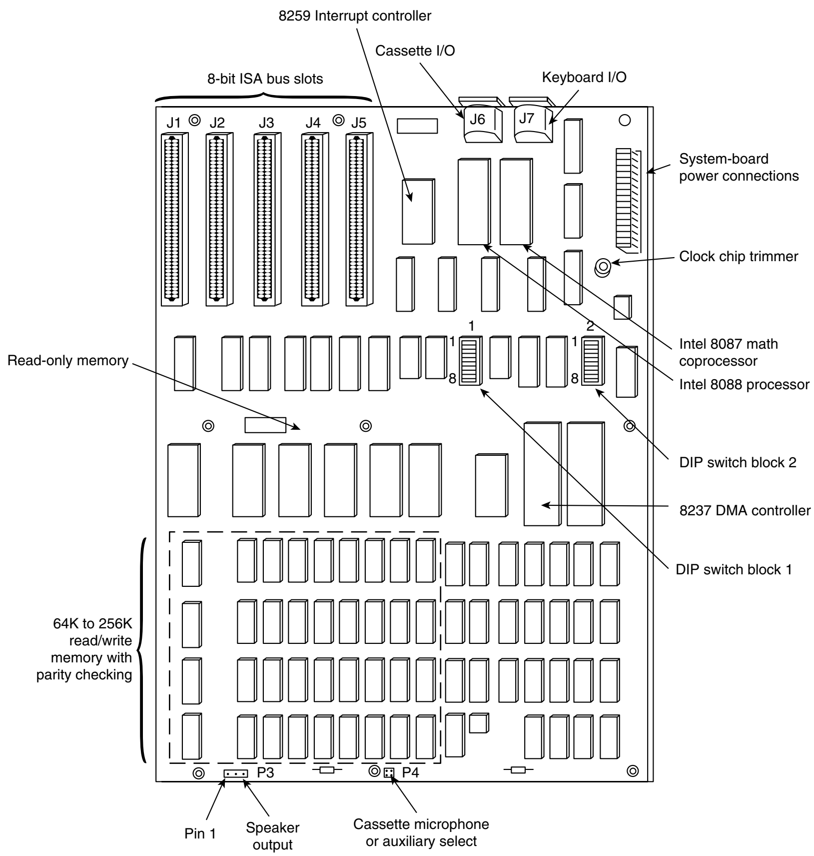


Figure 4.1 IBM PC motherboard (circa 1981).

The minor differences in the slot positions and the now-lonesome keyboard connector on the back required a minor redesign of the case. This motherboard became very popular, and many other PC motherboard manufacturers of the day copied IBM's XT design and produced similar boards. By the time most of these clones or compatible systems came out, IBM had released its AT system, which initially used a larger form factor motherboard. Due to the advances in circuit miniaturization, these companies found they could fit all the additional circuits found on the 16-bit AT motherboard into the XT motherboard form factor. Rather than call these boards XT-sized, which might have made people think they were 8-bit designs, these companies referred to them as Baby-AT, which ended up meaning an XT-sized board with AT motherboard design features (16-bit or greater).

Note

The CD accompanying this book contains detailed information on the PC (5150) and XT (5160). See the Technical Reference section of the CD. All the information there is printable.

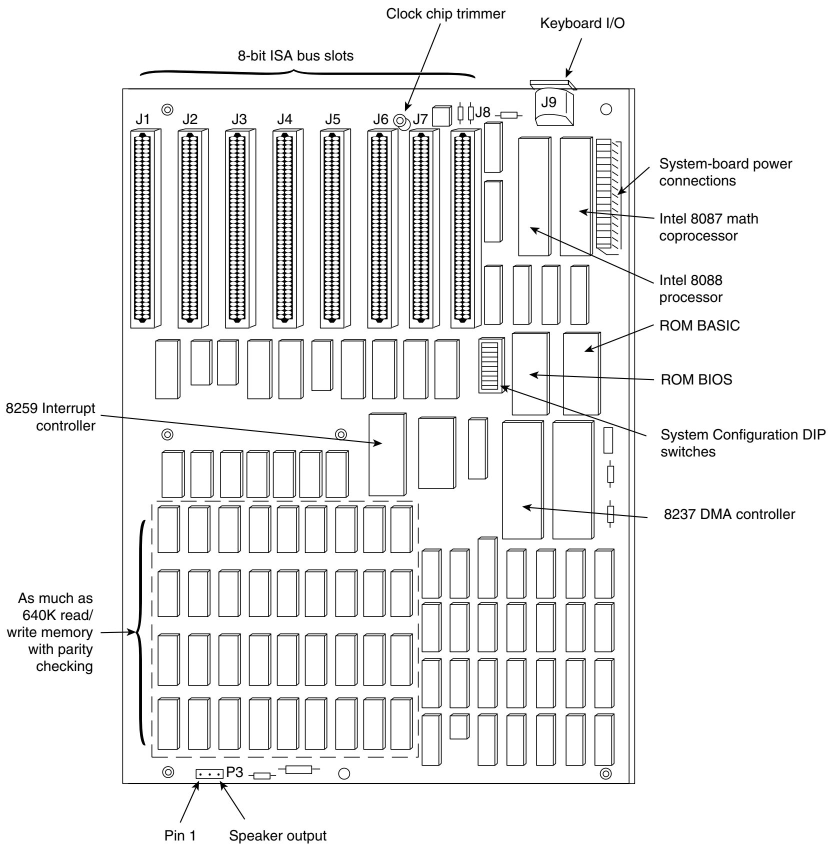

Figure 4.2 IBM PC-XT motherboard (circa 1983).

Thus, the Baby-AT form factor is essentially the same as the original IBM XT motherboard. The only difference is a slight modification in one of the screw hole positions to fit into an AT-style case. These motherboards also have specific placement of the keyboard and slot connectors to match the holes in the case. Note that virtually all full-size AT and Baby-AT motherboards use the standard 5-pin DIN type connector for the keyboard. Baby-AT motherboards can be used to replace full-sized AT motherboards and will fit into a number of case designs. Because of their flexibility, from 1983 into early 1996 the Baby-AT form factor was the most popular motherboard type. Starting in mid-1996, Baby-AT was replaced by the superior ATX motherboard design, which is not directly interchangeable. Most systems sold since 1996 have used the improved ATX, Micro-ATX, or NLX design, and Baby-AT is getting harder and harder to come by. Figure 4.3 shows the onboard features and layout of a late-model Baby-AT motherboard. Older Baby-AT motherboards have the same general layout but lack advanced features, such as USB connectors, DIMM memory sockets, and the AGP slot.

Any case that accepts a full-sized AT motherboard will also accept a Baby-AT design. Since its debut in the IBM XT motherboard in 1983 and lasting well into 1996, the Baby-AT motherboard form factor was, for that time, the most popular design. PC motherboards using the Baby-AT design have been manufactured to use virtually any processor from the original 8088 to the Pentium III or Athlon, although the pickings are slim where the newer processors are concerned. As such, systems with Baby-AT motherboards were the original upgradable systems. Because any Baby-AT motherboard can be replaced with any other Baby-AT motherboard, this is an interchangeable design. Even though the Baby-AT design (shown in Figure 4.3) is now obsolete, ATX carries on its philosophy of interchangeability. Figure 4.4 shows a more modern Baby-AT motherboard, which includes USB compatibility, SIMM and DIMM sockets, and even a supplemental ATX power supply connection.

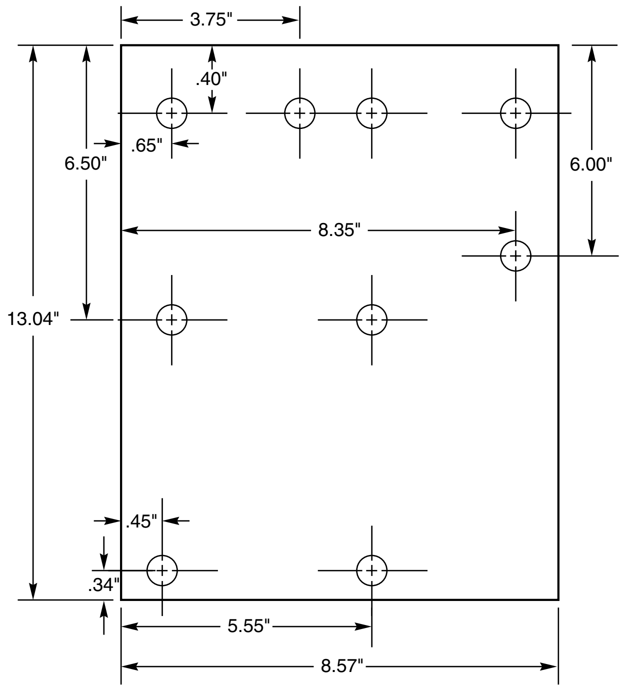

Figure 4.3 Baby-AT motherboard form factor dimensions.

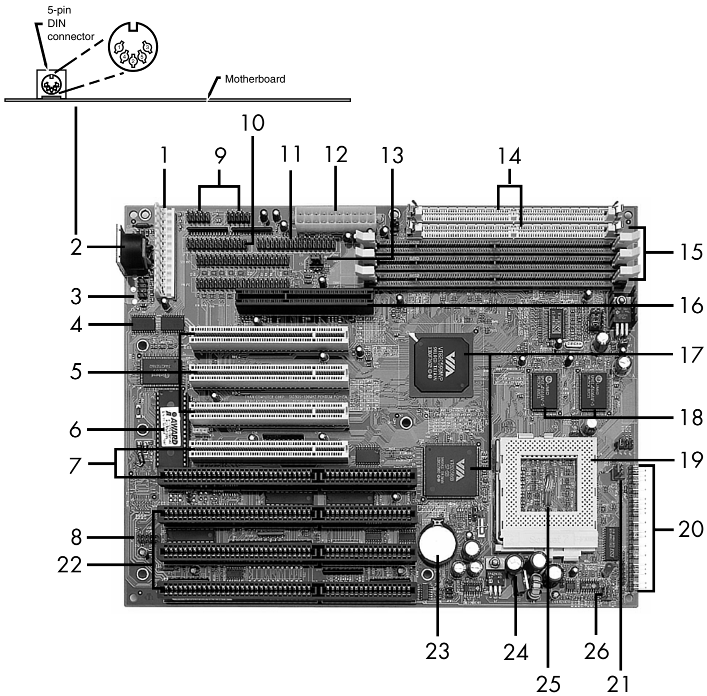
The easiest way to identify a Baby-AT form factor system without opening it is to look at the rear of the case. In a Baby-AT motherboard, the cards plug directly into the board at a 90° angle; in other words, the slots in the case for the cards are perpendicular to the motherboard. Also, the Baby-AT motherboard has only one visible connector directly attached to the board, which is the keyboard connector. Typically, this connector is the full-sized 5-pin DIN type connector, although some Baby-AT systems use the smaller 6-pin mini-DIN connector (sometimes called a PS/2 type connector) and might even have a mouse connector. All other connectors are mounted on the case or on card edge brackets and attached to the motherboard via cables. The keyboard connector is visible through an appropriately placed hole in the case.

▶▶ See "Keyboard/Mouse Interface Connectors," p. 969.

Baby-AT boards all conform to specific width, screw hole, slot, and keyboard connector locations, but one thing that can vary is the length of the board. Versions have been built that are shorter than the full 13-inch length; these are often called Mini-AT, Micro-AT, or even things such as 2/3-Baby or 1/2-Baby. Even though they might not have the full length, they still bolt directly into the same case as a standard Baby-AT board and can be used as a direct replacement for one.



1) LPX (12-pin) power supply connector
2) 5-pin DIN keyboard connector
3) PS/2 mouse port header cable connector
4) IDE host adapter cable connectors (2)
5) 32-bit PCI expansion slots (3)
6) BIOS chip
7) Combo PCI/ISA expansion slot
8) USB port header cable connector
9) COM (serial) ports header cable connectors (2)
10) LPT (parallel) port header cable connector
11) Floppy controller cable connector
12) ATX (20-pin) power supply connector
13) CPU fan power connector
14) 72-pin SIMM sockets (2)
15) 168-pin DIMM sockets (3)
16) AGP video card slot
17) VIA Apollo MVP 3 chipset (2 chips)
18) L2 cache memory (1MB total from 2 chips)
19) Super Socket 7 CPU socket
20) Connectors for case speaker, reset button, and other front panel devices
21) Case fan power connector
22) ISA expansion slots (3)
23) CR2032 battery for maintaining CMOS (RTC/NVRAM) contents
24) Voltage regulator assembly
25) CPU temperature sensor
26) CPU fan power connector

Full-Size AT

The full-size AT motherboard matches the original IBM AT motherboard design. This allows for a very large board of up to 12 inches wide by 13.8 inches deep. When the full-size AT board debuted in 1984, IBM needed more room for additional circuits when it migrated from the 8-bit architecture of the PC/XT to the 16-bit architecture of the AT. So, IBM started with an XT board and extended it in two directions (see Figure 4.5).

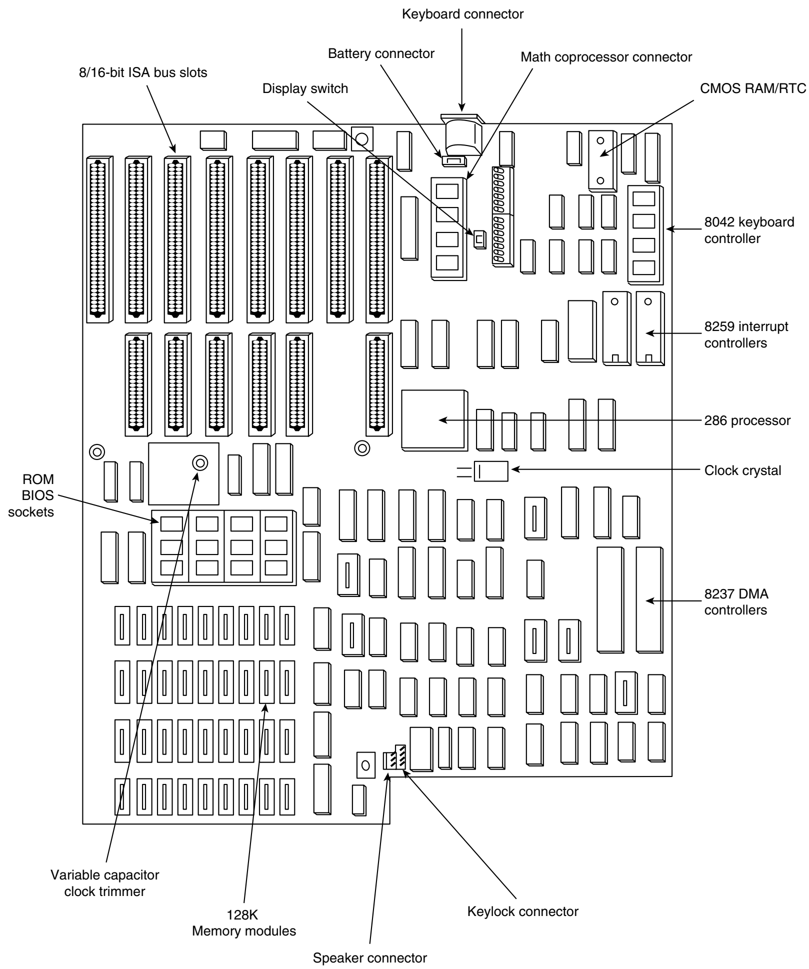

Figure 4.5 IBM AT motherboard (circa 1984).

The board was redesigned to make it slightly smaller a little over a year after being introduced. Then, as discussed previously, it was redesigned again as IBM shrank the board down to XT-size in a system it called the XT-286. The XT-286 board size was virtually identical to the original XT and was adopted by most PC-compatible manufacturers when it became known as Baby-AT.

Note

The enclosed CD contains detailed coverage of the AT and the XT Model 286. See the Technical Reference section of the CD for this legacy coverage.

The keyboard connector and slot connectors in the full-size AT boards still conformed to the same specific placement requirements to fit the holes in the XT cases already in use, but a larger case was still required to fit the larger board. Because of the larger size of the board, a full-size AT motherboard only fits into full-size AT desktop or tower cases. Because these motherboards do not fit into the smaller Baby-AT or mini-tower cases, and because of advances in component miniaturization, they are no longer being produced by most motherboard manufacturers—except in some cases for dual processor server applications.

Note that you can always replace a full-size AT motherboard with a Baby-AT board, but the opposite is not true unless the case is large enough to accommodate the full-size AT design.

LPX

The LPX and Mini-LPX form factor boards are a semiproprietary design originally developed by Western Digital in 1987 for some of its motherboards. The LP in LPX stands for Low Profile, which is so named because these boards incorporated slots that were parallel to the main board, enabling the expansion cards to install sideways. This allowed for a slim or low-profile case design and overall a smaller system than the Baby-AT.

Although Western Digital no longer produces PC motherboards, the form factor lives on, and many other motherboard manufacturers have duplicated the design. Unfortunately, because the specifications were never laid out in exact detail—especially with regard to the bus riser card portion of the design—these boards are termed semiproprietary and are not interchangeable between manufacturers. Some vendors, such as IBM and HP, for example, have built LPX systems that use a T-shaped riser card that allows expansion cards to be mounted at the normal 90° angle to the motherboard but still above the motherboard. This lack of standardization means that if you have a system with an LPX board, in most cases you will not be able to replace the motherboard with a different LPX board later. You essentially have a system you can't upgrade or repair by replacing the motherboard with something better. In other words, you have what I call a disposable PC, something I would not normally recommend that anybody purchase.

Most people were not aware of the semiproprietary nature of the design of these boards, and they were extremely popular in what I call "retail store" PCs from the late 1980s through the late 1990s. This would include primarily Compaq and Packard Bell systems, as well as many others who used this form factor in their lower-cost systems. These boards were most often used in low-profile or Slimline case systems but were also found in tower cases, too. These were often lower-cost systems such as those sold at retail electronics superstores. Although scarce even in retail chains today, because of their proprietary nature, I recommend staying away from any system that uses an LPX motherboard.

Tip

Normally, I would never recommend upgrading an LPX system—they simply aren't worth the expense. However, a few vendors do sell LPX motherboards, so if it's absolutely necessary, an upgrade might be possible. The problem is the riser card, which is typically sold separately from the motherboard itself. It is up to you to figure out which riser card will work in your existing case, and often, if you choose the wrong riser card, you're stuck with it.

If you must locate LPX-compatible products, try these Web sites and vendors:

- Unicorn Computers (Taiwan): `www.unicorn-computer.com.tw`
- Hong Faith America (Taiwan): `www.america.hongfaith.com`
- FriendTech's LPX Zone (`www.friendtech.com/LPX_Zone/LPX_Zone.htm`) has links to other vendors and is developing a comprehensive knowledge base of LPX-related information and possible upgrades.

LPX boards are characterized by several distinctive features (see Figure 4.6). The most noticeable is that the expansion slots are mounted on a bus riser card that plugs into the motherboard. In most designs, expansion cards plug sideways into the riser card. This sideways placement allows for the low-profile case design. Slots are located on one or both sides of the riser card depending on the system and case design. Vendors who use LPX-type motherboards in tower cases sometimes use a T-shaped riser card instead, which puts the expansion slots at the normal right angle to the motherboard but on a raised shelf above the motherboard itself.

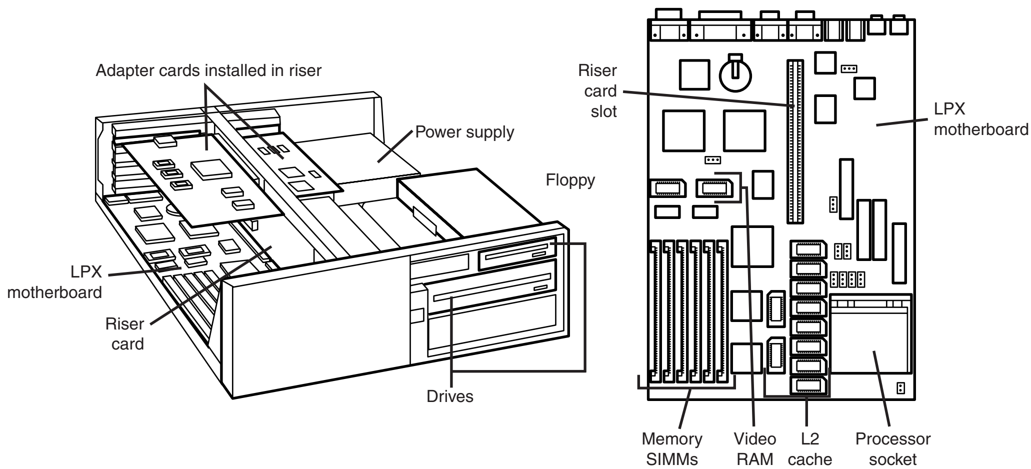

Figure 4.6 Typical LPX system chassis and motherboard.

Another distinguishing feature of the LPX design is the standard placement of connectors on the back of the board. An LPX board has a row of connectors for video (VGA 15-pin), parallel (25-pin), two serial ports (9-pin each), and mini-DIN PS/2 style mouse and keyboard connectors. All these connectors are mounted across the rear of the motherboard and protrude through a slot in the case. Some LPX motherboards might have additional connectors for other internal ports, such as network or SCSI adapters. Because LPX systems use a high degree of motherboard port integration, many vendors of LPX motherboards, cases, and systems often refer to LPX products as having an "all-in-one" design.

The standard form factor used for LPX and Mini-LPX motherboards used in many typical low-cost systems is shown in Figure 4.7.

I am often asked, "How can I tell whether a system has an LPX board without opening the cover?" Because of the many variations in riser card design, and because newer motherboards such as NLX also use riser cards, the most reliable way to distinguish an LPX motherboard from other systems is to look at the connector signature (the layout and pattern of connectors on the back of the board). As you can see in Figure 4.8, all LPX motherboards—regardless of variations in riser card shape, size, or location—place all external ports along the rear of the motherboard. By contrast, Baby-AT motherboards use case-mounted or expansion slot–mounted connectors for serial, parallel, PS/2 mouse, and USB ports, whereas ATX-family motherboards group all external ports together to the left side of the expansion slots.

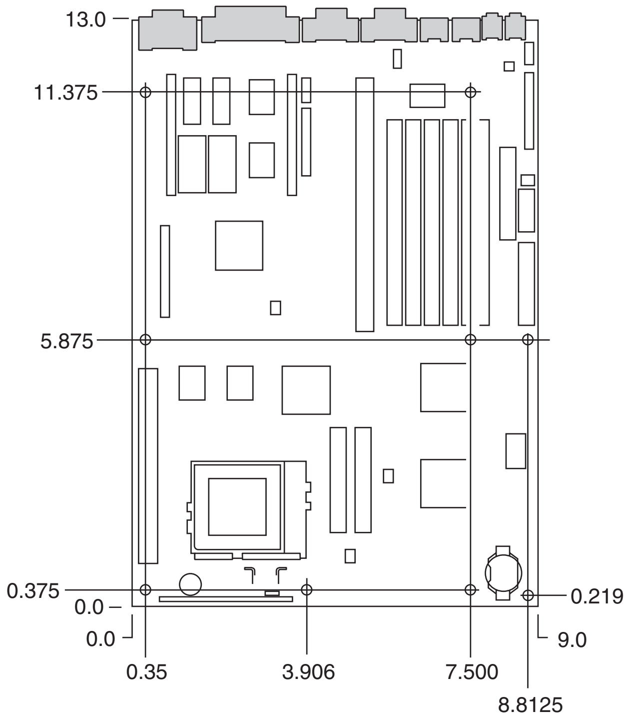

Figure 4.7 LPX motherboard dimensions.

On an LPX board, the riser is placed in the middle of the motherboard, whereas NLX boards have the riser to the side (the motherboard actually plugs into the riser in NLX).

Figure 4.8 shows two typical examples of the connectors on the back of LPX boards. Note that not all LPX boards have the built-in audio, so those connectors might be missing. Other ports (such as USB) might be missing from what is shown in these diagrams, depending on exactly what options are included on a specific board; however, the general layout will be the same.

The connectors along the rear of the board would interfere with locating bus slots directly on the motherboard, which accounts for why riser cards are used for adding expansion boards.

Although the built-in connectors on the LPX boards were a good idea, unfortunately the LPX design was semiproprietary (not a fully interchangeable standard) and thus, not a good choice. Newer motherboard form factors such as ATX, Micro-ATX, and NLX have both built-in connectors and use a standard board design. The riser card design of LPX allowed system designers to create a low-profile desktop system, a feature now carried by the much more standardized NLX form factor. In fact, NLX was developed as the modern replacement for LPX.

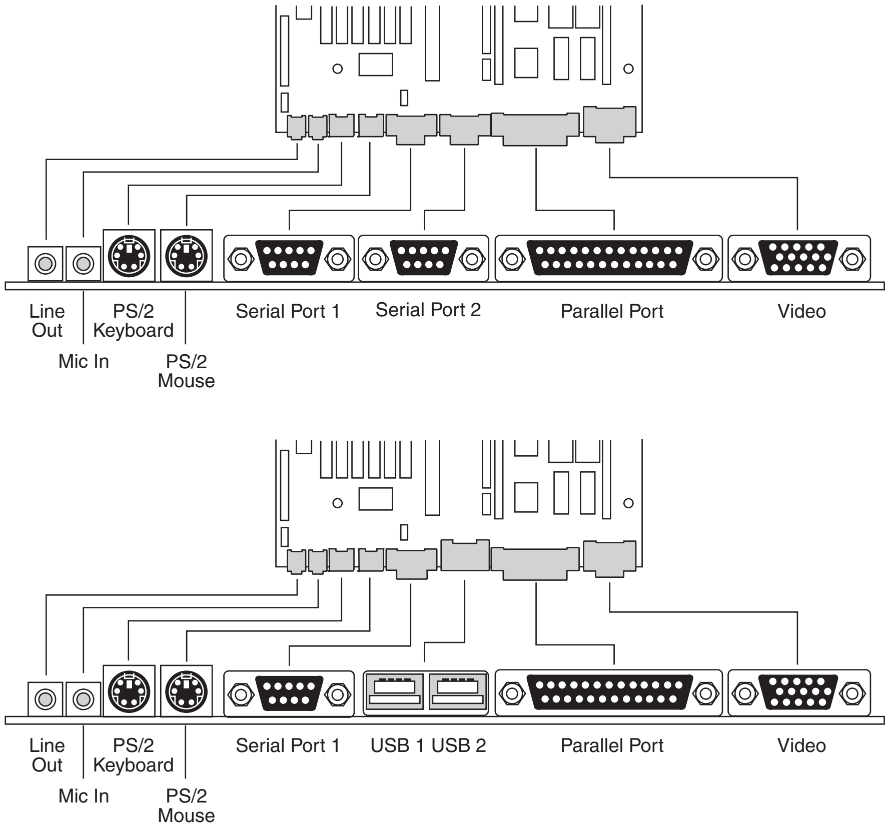

Figure 4.8 LPX motherboard back panel connectors.

ATX

The ATX form factor was the first of a dramatic evolution in motherboard form factors. ATX is a combination of the best features of the Baby-AT and LPX motherboard designs, with many new enhancements and features thrown in. The ATX form factor is essentially a Baby-AT motherboard turned sideways in the chassis, along with a modified power supply location and connector. The most important thing to know initially about the ATX form factor is that it is physically incompatible with either the previous Baby-AT or LPX design. In other words, a different case and power supply are required to match the ATX motherboard. These case and power supply designs have become common and are found in most new systems.

The official ATX specification was initially released by Intel in July 1995 and was written as an open specification for the industry. ATX boards didn't hit the market in force until mid-1996, when they rapidly began replacing Baby-AT boards in new systems. The ATX specification was updated to version 2.01 in February 1997, and has had several minor revisions since. The latest revision is ATX version 2.03 (with Engineering Change Revision P1), released in May 2000. Intel has published detailed specifications so other manufacturers can use the ATX design in their systems. The current specifications for ATX and other current motherboard types are available online from the Desktop Form Factors site, `www.formfactors.org`. Currently, ATX is the most popular motherboard form factor for new systems, and it is the one I recommend most people get in their systems today. An ATX system will be upgradable for many years to come, exactly like Baby-AT was in the past.

ATX improved on the Baby-AT and LPX motherboard designs in several major areas:

- *Built-in double high external I/O connector panel*. The rear portion of the motherboard includes a stacked I/O connector area that is 6 1/4-inches wide by 1 3/4-inches tall. This enables external connectors to be located directly on the board and negates the need for cables running from internal connectors to the back of the case as with Baby-AT designs.
- *Single main keyed internal power supply connector.* This is a boon for the average end user who always had to worry about interchanging the Baby-AT power supply connectors and subsequently blowing the motherboard! The ATX specification includes a keyed and shrouded main power connector that is easy to plug in and can't be installed incorrectly. This connector also features pins for supplying 3.3v to the motherboard, so ATX motherboards do not require built-in voltage regulators that are susceptible to failure. The ATX specification was extended to include two additional optional keyed power connectors called the Auxiliary Power connector (3.3V and 5V) and the ATX12V connector for systems that require more power than the original specification would allow.

▶▶ See "AT Power Supply Connectors," p. 1117.

- *Relocated CPU and memory.* The CPU and memory modules are relocated so they can't interfere with any bus expansion cards and can easily be accessed for upgrade without removing any of the installed bus adapters. The CPU and memory are relocated next to the power supply, which is where the primary system fan is located. The improved airflow concentrated over the processor, in some cases, eliminates the need for extra-cost CPU cooling fans (lower power configurations only). There is room for a CPU and heatsink of up to 2.8 inches in height, as well as more than adequate side clearance provided in that area.

Note

Note that most systems still require additional processor cooling, either from a case-mounted fan or an active heatsink with an integral fan. Intel and AMD supply processors with attached high-quality (ball bearing) fans for CPUs sold to smaller vendors. These are so-called "boxed" processors because they are sold in single-unit box quantities instead of cases of 100 or more like the raw CPUs sold to the larger vendors. The included fan heatsink is a form of thermal insurance because most smaller vendors and system self-assemblers lack the engineering knowledge necessary to perform thermal analysis, temperature measurements, and the testing required to select the properly sized passive heatsinks. The only thermal requirement spelled out for the boxed processors is that the temperature of the air entering the active heatsink (usually the same as the system interior ambient temperature) is kept to 45°C (113°F) or less in Pentium III or earlier models, or 40°C (104°F) or less in the Pentium 4 or later processors. By putting a high-quality fan on these "boxed" processors, Intel and AMD can put a warranty on the boxed processors that is independent of the system warranty. Larger vendors have the engineering talent to select the proper passive heatsink, thus reducing the cost of the system as well as increasing reliability. With an OEM non-boxed processor, the warranty is with the system vendor and not the processor manufacturer directly. Heatsink mounting instructions usually are included with a motherboard if non-boxed processors are used.

- *Relocated internal I/O connectors*. The internal I/O connectors for the floppy and hard disk drives are relocated to be near the drive bays and out from under the expansion board slot and drive bay areas. This means that internal cables to the drives can be much shorter, and accessing the connectors does not require card or drive removal.
- *Improved cooling.* The CPU and main memory are designed and positioned to improve overall system cooling. This can decrease—but not necessarily eliminate—the need for separate case or CPU cooling fans. Most higher-speed systems still need additional cooling fans for the CPU and chassis. Note that the ATX specification originally specified that the ATX power supply fan blows into the system chassis instead of outward. This reverse flow, or positive pressure design,

pressurizes the case, which minimizes dust and dirt intrusion. More recently, the ATX specification was revised to allow the more normal standard flow, which negatively pressurizes the case by having the fan blow outward. Because the specification technically allows either type of airflow, and because some overall cooling efficiency is lost with the reverse flow design, most power supply manufacturers provide ATX power supplies with fans that exhaust air from the system, otherwise called a negative pressure design. See Chapter 21, "Power Supply and Chassis/Case," for more detailed information.

- *Lower cost to manufacture.* The ATX specification eliminates the need for the rat's nest of cables to external port connectors found on Baby-AT motherboards, additional CPU or chassis cooling fans, or onboard 3.3v voltage regulators. Instead, ATX allows for shorter internal drive cables and no cables for standard external serial or parallel ports. These all conspire to greatly reduce the cost of the motherboard and the cost of a complete system—including the case and power supply.

Figure 4.9 shows the new ATX system layout and chassis features, as you would see them looking in with the lid off on a desktop, or sideways in a tower with the side panel removed. Notice how virtually the entire motherboard is clear of the drive bays and how the devices such as CPU, memory, and internal drive connectors are easy to access and do not interfere with the bus slots. Also notice how the processor is positioned near the power supply.

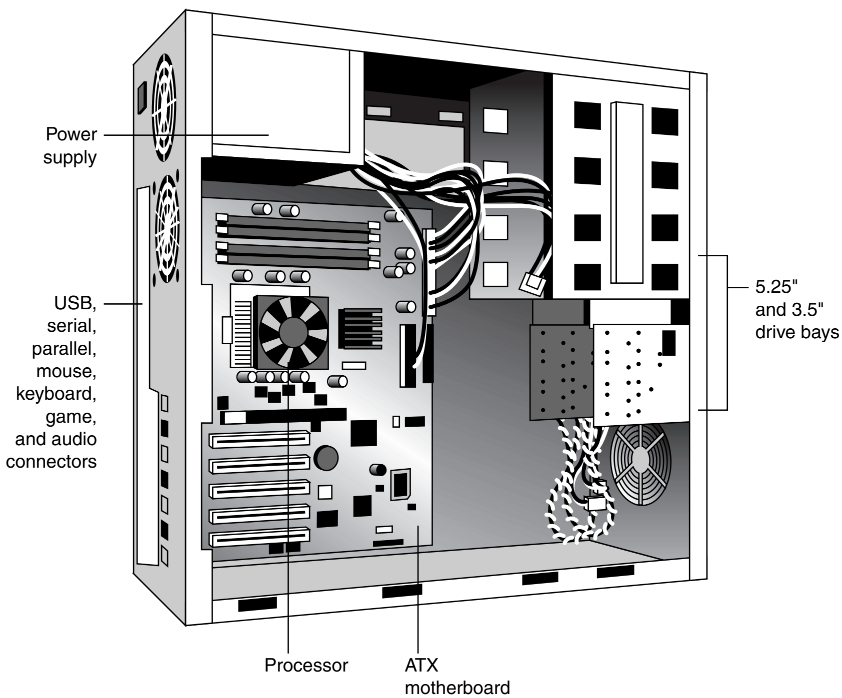

Figure 4.9 When mounted inside the case, the ATX motherboard is oriented so that the CPU socket is near the power supply fan and case fan (if your case includes one).

The ATX motherboard shape is basically a Baby-AT design rotated sideways 90°. The expansion slots are now parallel to the shorter side dimension and do not interfere with the CPU, memory, or I/O connector sockets (see Figure 4.10). There are actually two basic sizes of standard ATX boards. In addition to a full-size ATX layout, Intel also has specified a mini-ATX design, which is a fully compatible subset in size and will fit into the same case:

- A full-size ATX board is 12" wide × 9.6" deep (305mm×244mm).
- The mini-ATX board is 11.2" × 8.2" (284mm×208mm).

In addition, two smaller variations of ATX exist, called Micro-ATX and Flex-ATX. They are discussed in the following sections in this chapter.

Although the case holes are similar to the Baby-AT case, cases for the two formats are generally not compatible. The power supplies require a connector adapter to be interchangeable, but the basic ATX power supply design is similar to the standard Slimline power supply.

Clearly, the advantages of the ATX form factor make it the best choice for new systems. For backward compatibility, you can still find Baby-AT boards for use in upgrading older systems, but the choices are becoming slimmer every day. I would never recommend building or purchasing a new system with a Baby-AT motherboard because you will severely limit your future upgrade possibilities. In fact, I have been recommending only ATX systems for new system purchases since late 1996 and will probably continue to do so for the next several years.

The best way to tell whether your system has an ATX-board design without removing the lid is to look at the back of the system. Two distinguishing features identify ATX. One is that the expansion boards plug directly into the motherboard. There is usually no riser card as with LPX or NLX, so the slots are perpendicular to the plane of the motherboard. Also, ATX boards have a unique double-high connector area for all the built-in connectors on the motherboard (see Figure 4.11). This is found just to the side of the bus slot area and can be used to easily identify an ATX board.

Note

Although Figure 4.11 shows typical ATX rear-panel connectors, many variations are already available, and more are coming in the future. For example, systems with integrated video will have a VGA 15-pin connector in addition to those shown, whereas systems that use a separate sound card will omit the MIDI/game port and audio jacks.

In the future, you can expect to see more and more so-called "legacy-free" systems that omit the serial and parallel ports, and at some point in the future, even the PS/2 mouse and keyboard ports might be dropped because USB devices can be used for all the functions currently performed by these ports.

The specification and related information about the ATX, mini-ATX, micro-ATX, flex-ATX, or NLX form factor specifications are available from the Form Factors (formerly Platform Developer) Web site at `http://www.formfactors.org`. The Form Factors site provides form factor specifications and design guides, as well as design considerations for new technologies, information on initiative supporters, vendor products, and a form factor discussion forum.

Micro-ATX

Micro-ATX is a motherboard form factor originally introduced by Intel in December of 1997 as an evolution of the ATX form factor for smaller and lower-cost systems. The reduced size as compared to standard ATX allows for a smaller chassis, motherboard, and power supply, reducing the cost of entire system. The micro-ATX form factor is also backward compatible with the ATX form factor and can be used in full-size ATX cases. Of course, a micro-ATX case doesn't take a full-size ATX board. During early 1999, this form factor began to really catch on in the low-cost, sub-$1,000 PC market. Currently, mini-tower chassis systems dominate the low-cost PC market, although their small sizes and cramped interiors severely limit future upgradability.

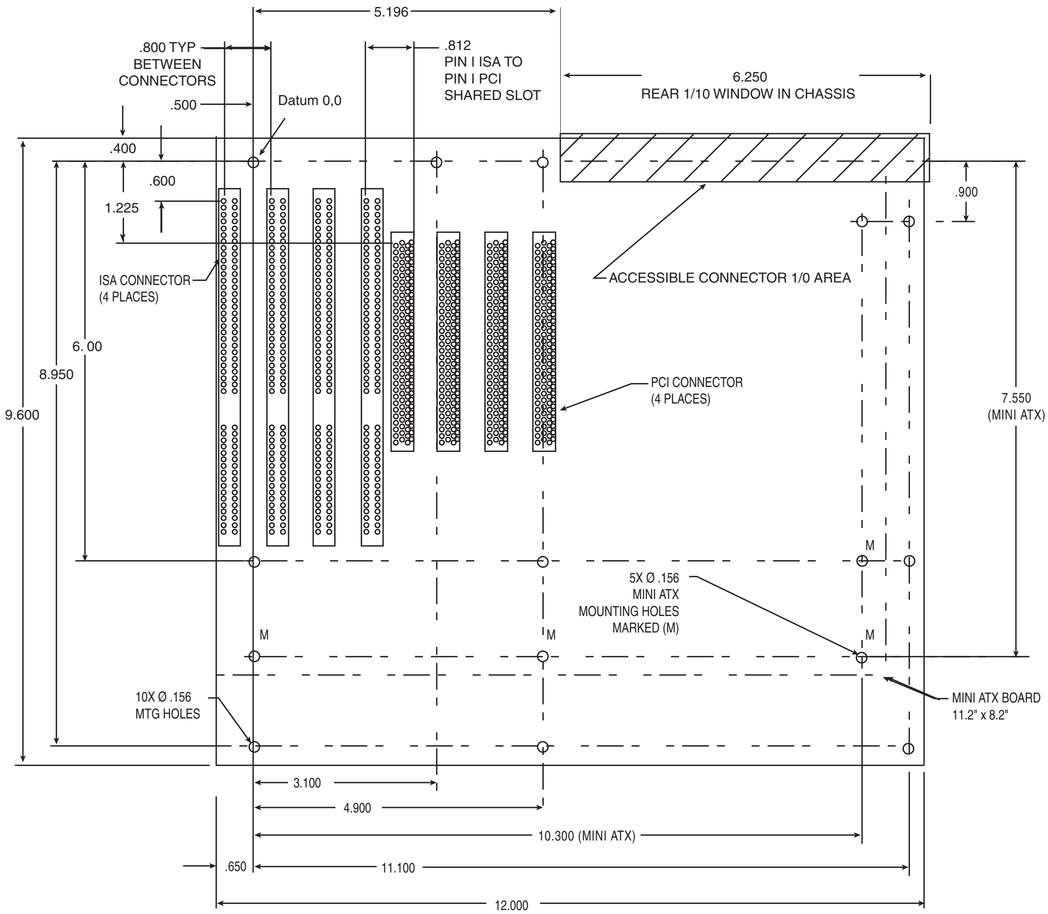

Figure 4.10 ATX specification version 2.03, showing ATX and mini-ATX dimensions.

The main differences between micro-ATX and standard or mini-ATX are as follows:

- Reduced width motherboard (9.6" [244mm] instead of 12" [305mm] or 11.2" [284mm])
- Fewer I/O bus expansion slots (four maximum, although most boards feature only three)
- Smaller power supply optional(SFX form factor)

The micro-ATX motherboard maximum size is only 9.6" × 9.6" (244mm×244mm) as compared to the full-size ATX size of 12" × 9.6" (305mm×244mm) or the mini-ATX size of 11.2" × 8.2" (284mm×208mm). Even smaller boards can be designed as long as they conform to the location of the mounting holes, connector positions, and so on, as defined by the standard. Fewer slots aren't a problem for typical home or small-business PC users because more components such as sound and video are usually integrated on the motherboard and therefore don't require separate slots. This higher integration reduces motherboard and system costs. External buses, such as USB, 10/100 Ethernet, and optionally SCSI or 1394 (FireWire), can provide additional expansion out of the box. The specifications for micro-ATX motherboard dimensions are shown in Figure 4.12.

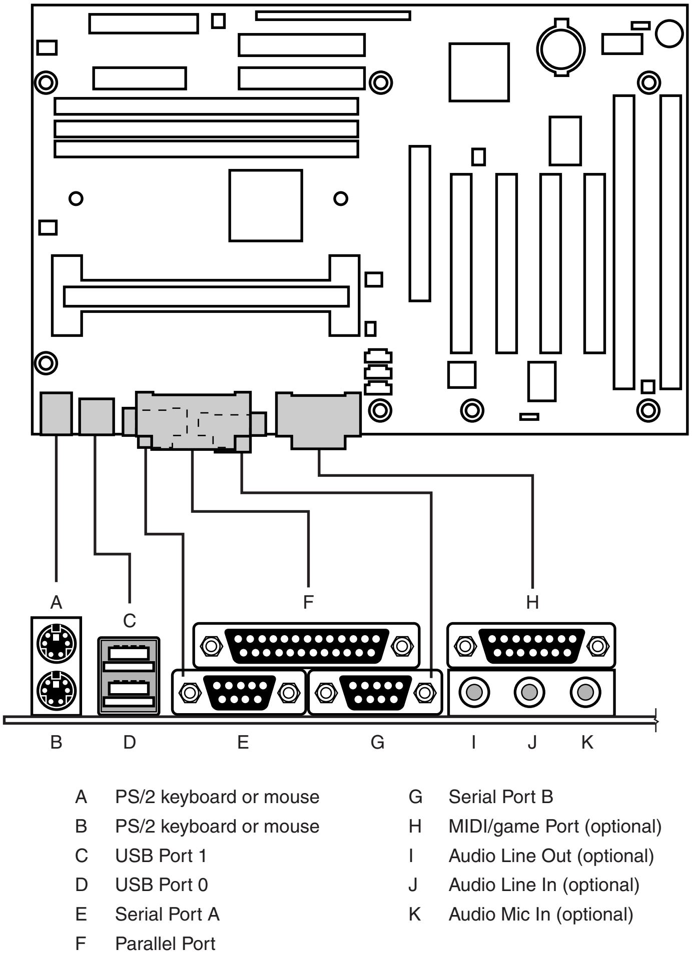

Figure 4.11 Typical ATX motherboard rear panel connectors.

A new, small form factor (called SFX) power supply has been defined for optional use with micro-ATX systems, although the standard ATX supply also works fine because the connectors are the same. The smaller size of the SFX power supply encourages flexibility in choosing mounting locations within the chassis and allows for smaller systems that consume less power overall. Although the smaller SFX power supply can be used, it lacks sufficient power output for faster or fully configured systems. Because of the high power demands of most modern systems, most micro-ATX chassis are designed to accept standard ATX power supplies.

▶▶ See "SFX Style," p. 1114.

The micro-ATX form factor is similar to ATX for compatibility. The similarities include the following:

- Standard ATX 20-pin power connector
- Standard ATX I/O panel
- Mounting holes are a subset of ATX

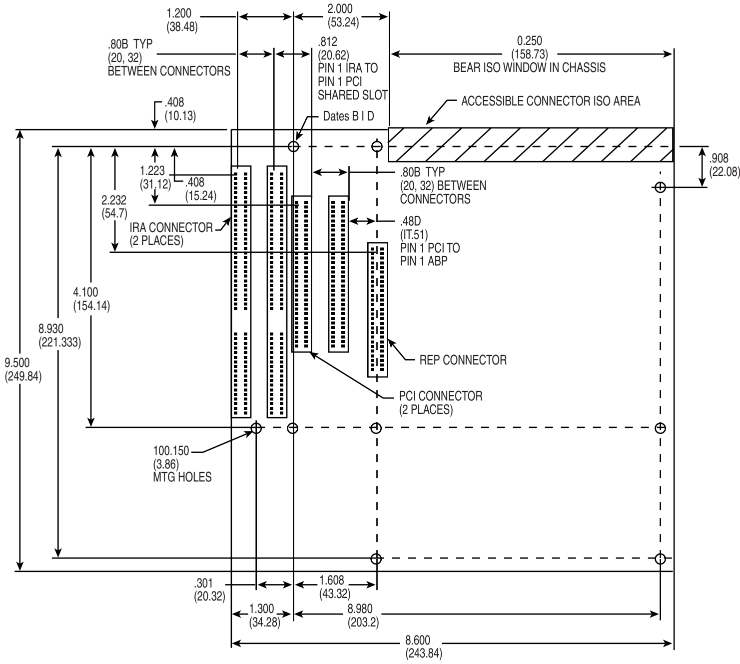

Figure 4.12 Micro-ATX specification 1.0 motherboard dimensions.

These similarities ensure that a micro-ATX motherboard will easily work in a standard ATX chassis with a standard ATX power supply, as well as the smaller micro-ATX chassis and SFX power supply.

The overall system size for a micro-ATX is very small. A typical case is only 12" to 14" tall, about 7" wide, and 12" deep. This results in a kind of micro-tower or desktop size. A typical micro-ATX motherboard is shown in Figure 4.13.

As with ATX, micro-ATX was released to the public domain by Intel to facilitate adoption as a de facto standard. The specification and related information on micro-ATX are available through the Desktop Form Factors site (`www.formfactors.org`).

Flex-ATX

In March of 1999, Intel released the flex-ATX addendum to the micro-ATX specification. This added a new and even smaller variation of the ATX form factor to the motherboard scene. Flex-ATX's smaller design is intended to allow a variety of new PC designs, especially extremely inexpensive, smaller, consumer-oriented, appliance-type systems.

Flex-ATX defines a board that is only 9.0" × 7.5" (229mm×191mm) in size, which is the smallest of the ATX family boards. Besides the smaller size, the other biggest difference between the flex-ATX form factor and the micro-ATX is that flex-ATX supports only socketed processors. Therefore, a flex-ATX board does not have a Slot 1, Slot 2, or Slot A–type connector for the cartridge versions of the Pentium II/III and Athlon processors. However, it can have Socket 7 or Socket A for AMD processors, Socket 370 for the PPGA (Plastic Pin Grid Array), FCPGA (Flip Chip PGA) versions of the Intel Celeron and Pentium III, or the newer Socket 423 for the Pentium 4. Because both Intel and AMD use socketed processors for their newest designs, the loss of compatibility with slot-based processors is no great sacrifice.

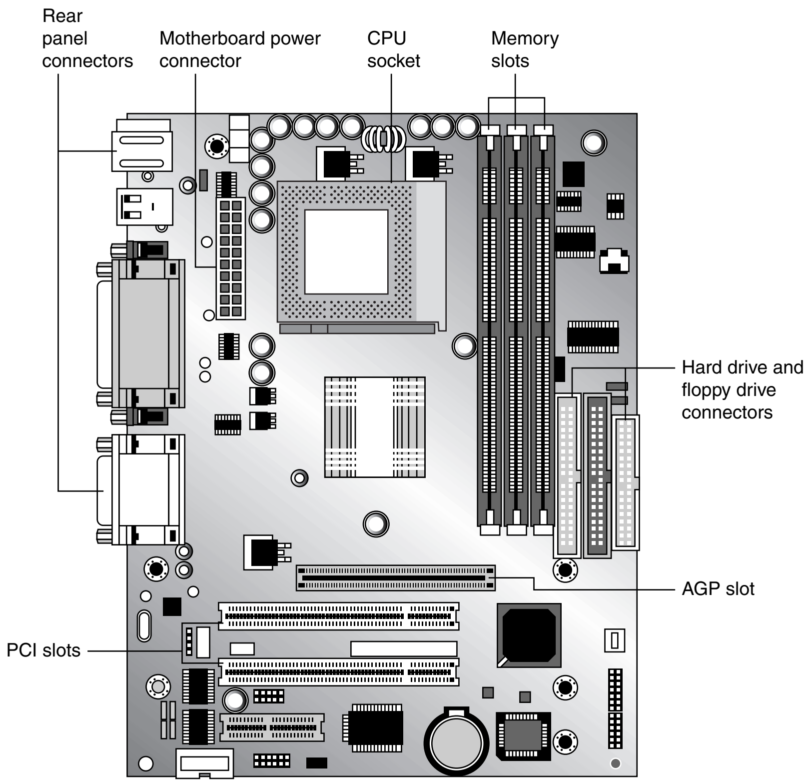

Figure 4.13 A typical micro-ATX motherboard's dimensions are 9.6"×9.6".

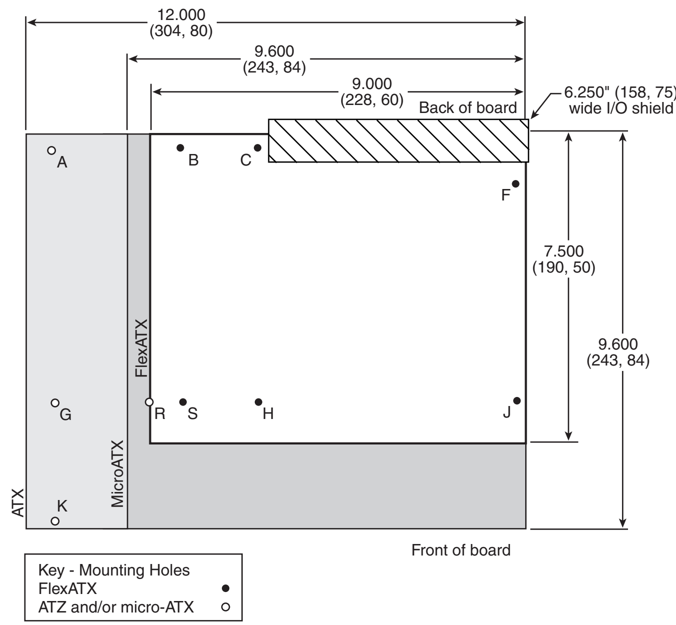
Besides the smaller size and socketed processor–only requirement, the rest of flex-ATX is backward compatible with standard ATX, using a subset of the mounting holes and the same I/O and power supply connector specifications (see Figure 4.14).

Most flex-ATX systems likely use the SFX (small form factor) type power supplies (introduced in the micro-ATX specification), although if the chassis allows it, a standard ATX power supply can also be used.

Note

Some motherboards, especially those used in server systems, come in nonstandard ATX variations collectively called *extended ATX*. This is a term applied to any board larger than the ATX standard. Note that because no official "extended ATX" standard exists, any board claiming this is unique in shape or size and might not fit in your existing chassis. If purchasing any so-called extended ATX board, be sure that it will fit in the chassis you intend to use. Dual Xeon processors fit in a standard ATX-size board, so choose a standard ATX-size board for maximum compatibility with the existing ATX chassis.

With the addition of flex-ATX, the family of ATX boards has now grown to include four definitions of size, as shown in Table 4.2.



Form Factor	Mounting Hole Locations	Notes
• FlexATX	B, C, F, H, J, S	
• Micro-ATX	B, C, F, H, J, L, M, R, S	Holes R and S were added for micro-ATX form factor. Hole B was defined in full-AT format.
• ATX	A, C, F, G, H, J, K, L, M	Hole F must be implemented in all ATX 2.03–compliant chassis assemblies. The hole was optional in the ATX 1.1 specification.

Figure 4.14 Size and mounting hole comparison between ATX, micro-ATX, and flex-ATX motherboards.

Table 4.2 ATX Motherboard Form Factors

Form Factor	Max. Width	Max. Depth
ATX	12.0" (305mm)	9.6" (244mm)
Mini-ATX	11.2" (284mm)	8.2" (208mm)
Micro-ATX	9.6" (244mm)	9.6" (244mm)
Flex-ATX	9.0" (229mm)	7.5" (191mm)

Note that these dimensions are the maximum the board can be. Making a board smaller is always possible as long as it conforms to the mounting hole and connector placement requirements detailed in the respective specifications. Each board has the same basic screw hole and connector placement requirements, so if you have a case that fits a full-size ATX board, you could also mount a mini-, micro-, or flex-ATX board in that same case. Obviously, if you have a smaller case designed for micro-ATX or flex-ATX, you won't be able to put the larger mini-ATX or full-size ATX boards in that case.

ATX Riser

In December 1999, Intel introduced a riser card design modification for ATX motherboards. The design includes the addition of a 22-pin (2×11) connector to one of the PCI slots on the motherboard, along with a two- or three-slot riser card that plugs in. The riser enables two or three PCI cards to be installed. Note that the riser does not support AGP.

ATX motherboards typically are found in vertically oriented tower-type cases, but often a horizontal desktop system is desired for a particular application. When ATX boards are installed in desktop cases, PCI cards can be as tall as 4.2 inches, thus requiring a case that is at least 6–7 inches tall. For Slimline desktop systems, most manufacturers now use the NLX format, but the more complex design and lower popularity of NLX makes that a more expensive alternative. What was needed was a low-cost way to use an industry-standard ATX form factor board in a Slimline desktop case. The best long-term solution to this problem is the eventual adoption of a lower-profile PCI card design that is shorter than the current 4.2 inches. The PCI Low-Profile specification was released for engineering review by the Peripheral Component Interconnect Special Interest Group (PCI SIG) on February 14, 2000, and some PCI card products are now being produced in this shorter (2.5-inch) form factor. Until Low-Profile PCI becomes widespread, Intel has suggested a riser card approach to enable standard-height PCI cards to be used in Slimline and rack-mount systems.

By adding a small 22-pin extension connector to one of the PCI slots on a motherboard, the necessary additional signals for riser card support could be implemented. The current design allows for the use of a two- or three-slot riser that is either 2 inches or 2.8 inches tall, respectively. To this riser, you can attach full-length cards sideways in the system. The motherboard can be used with or without the riser. The only caveat is that if a riser card is installed, the remaining PCI slots on the motherboard can't be used. You can have expansion cards plugged into only the riser or the motherboard, but not both. The riser card supports only PCI cards, not AGP or ISA cards. An sample ATX board with riser installed is shown in Figure 4.15.

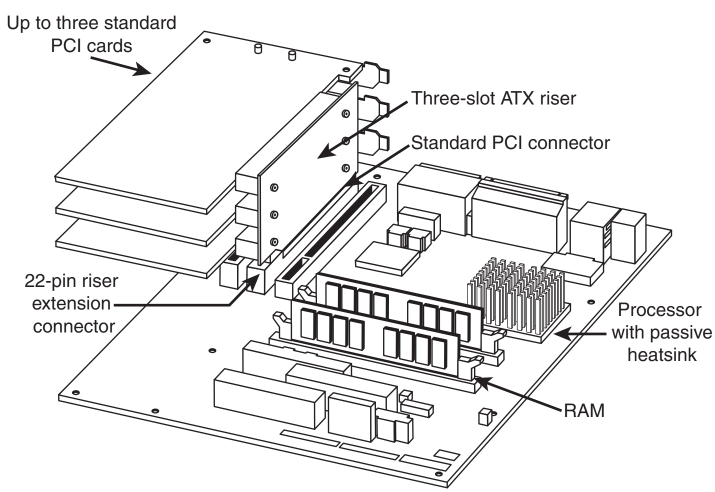


Figure 4.15 Three-slot ATX riser implementation on a micro-ATX motherboard.

The 22-pin extension connector usually is installed in line with PCI slot 6, which is the second one from the right—the slots are normally numbered from right to left (facing the board) starting with 7 as the one closest to the processor. Some boards number the slots from right to left starting with 1; in that case, the extension connector is on PCI slot 2. The pinout of the ATX 22-pin riser extension connector is shown in Figure 4.16.

Signal	Pin	Pin	Signal
Ground	B1	A1	PCI_GNT1#
PCI_ CLK1	B2	A2	Ground
Ground	B3	A3	PCI_GNT2#
PCI_REQ1#	A4	B4	Ground
Ground	A5	B5	PCI_CLK3
PCI_CLK2	A6	B6	RISER_ID1
Ground	A7	B7	Reserved
PCI_REQ2#	A8	B8	RISER_ID2
Ground	A9	B9	NOGO
PC/PCI_DREQ#	A10	B10	+12V
PC/PCI_DGNT#	A11	B11	SER_IRQ

Figure 4.16 ATX 22-pin riser extension connector pinout.

The PCI connector that is in line with the riser extension connector is just a standard PCI slot; none of the signals are changed.

Systems that use the riser generally are low-profile designs. Therefore, they don't fit normal PCI or AGP cards in the remaining (nonriser-bound) slots. Although the ATX riser standard originally was developed for use with low-end boards, which have integrated video, sound, and network support, many rack-mounted servers are also using the ATX riser because these boards also have most of their required components already integrated. In fact, the ATX riser appears to be more popular for rack-mounted servers than for the originally intended target market of Slimline desktop systems.

ATX riser cards, compatible cases, and compatible motherboards are available from a variety of vendors, though, allowing you to build your own Slimline ATX system.

NLX

NLX is a low-profile form factor designed to replace the nonstandard LPX design used in previous low-profile systems. First introduced in November of 1996 by Intel, NLX has become the form factor of choice for Slimline corporate desktop systems. NLX is similar in initial appearance to LPX, but with numerous improvements designed to enable full integration of the latest technologies. NLX is basically an improved version of the proprietary LPX design, but, unlike LPX, NLX is fully standardized, which means you should be able to replace one NLX board with another from a different manufacturer—something that was not possible with LPX.

Another limitation of LPX boards is the difficulty in handling the larger physical size of the newer processors and their larger heatsinks, as well as newer bus structures such as AGP for video. The NLX form factor has been designed specifically to address these problems (see Figure 4.17). In fact, NLX provides enough room for some vendors to support dual Slot 1 Pentium III processors in this form factor.

The main characteristic of an NLX system is that the motherboard plugs into the riser, unlike LPX where the riser plugs into the motherboard. This means the motherboard can be removed from the system without disturbing the riser or any of the expansion cards plugged into it. In addition, the motherboard in a typical NLX system literally has no internal cables or connectors attached to it! All devices that normally plug into the motherboard—such as drive cables, the power supply, the front panel light, switch connectors, and so on—plug into the riser instead (see Figure 4.18). By using the riser card as a connector concentration point, you can remove the lid on an NLX system and literally slide the motherboard out the left side of the system without unplugging a single cable or connector on the inside. This allows for unbelievably quick motherboard changes; in fact, I have swapped motherboards in less than 30 seconds on NLX systems!

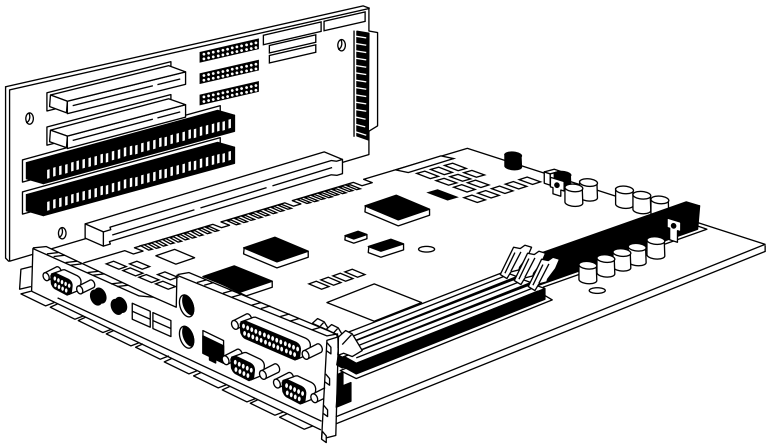

Figure 4.17 NLX motherboard and riser combination.

As Figure 4.18 shows, by using different sizes and types of riser cards, a system designer can customize the features of a given NLX system.

Such a design is a boon for the corporate market, where ease and swiftness of servicing is a major feature. Not only can components be replaced with lightning speed, but because of the industry-standard design, motherboards, power supplies, and other components are interchangeable even among different systems.

Specific advantages of the NLX form factor include

- *Support for all desktop system processor technologies*. This is especially important in the later processors that are not only larger but also require larger heatsinks to cool them.
- *Flexibility in the face of rapidly changing processor technologies*. Backplane-like flexibility has been built into the form by allowing a new motherboard to be easily and quickly installed without tearing your entire system to pieces. But unlike traditional backplane systems, many industry leaders, such as Compaq, Toshiba, and HP, are selling NLX-based systems.
- *Support for newer technologies*. This includes Accelerated Graphics Port (AGP) high-performance graphic solutions, Universal Serial Bus (USB), and memory modules in DIMM or RIMM form.
- *Ease and speed of servicing and repair.* Compared to other industry-standard interchangeable form factors, NLX systems are by far the easiest to work on and allow component swaps or other servicing in the shortest amount of time.

Furthermore, with the importance of multimedia applications, connectivity support for such things as video playback, enhanced graphics, and extended audio has been built into the motherboard. This should represent a good cost savings over expensive daughterboard arrangements that have been necessary for many advanced multimedia uses in the past. Although ATX also has this support, LPX and Baby-AT don't have the room for these additional connectors.

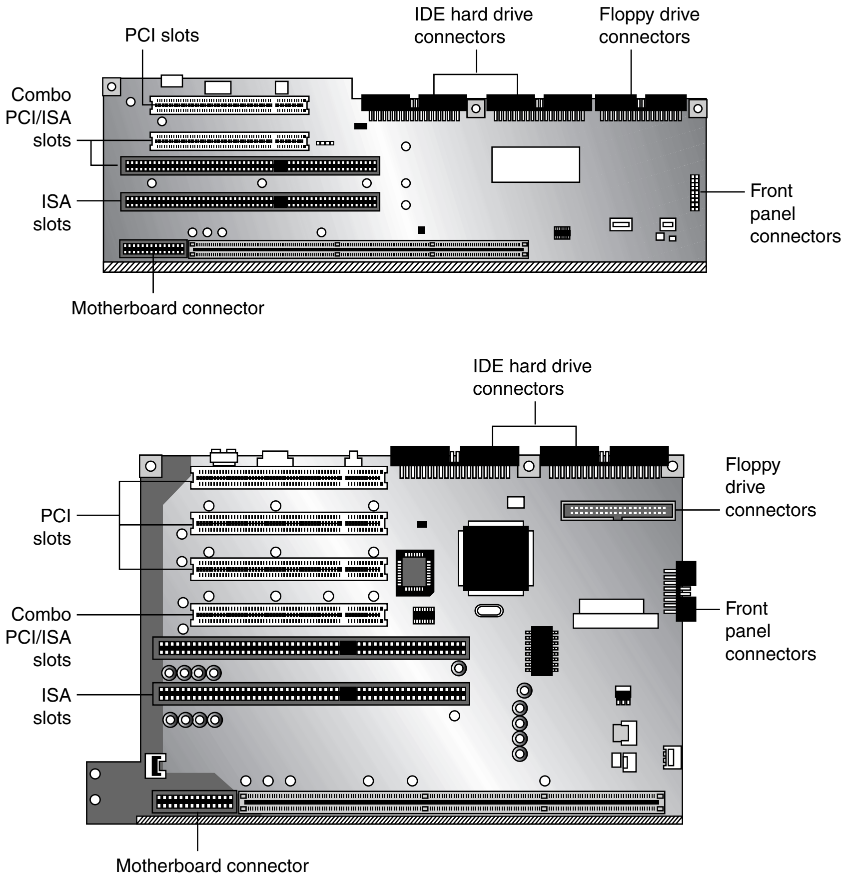

Figure 4.18 Typical NLX riser cards. Although most NLX systems use a low-profile riser card similar to the top riser card, others use a taller riser card to provide more slots for add-on cards.

Figure 4.19 shows the basic NLX system layout. Notice that, similar to ATX, the motherboard is clear of the drive bays and other chassis-mounted components. Also, the motherboard and I/O cards (which, like the LPX form factor, are mounted parallel to the motherboard) can easily be slid in and out of the side of the chassis, leaving the riser card and other cards in place. The processor can be easily accessed and enjoys greater cooling than in a more closed-in layout.

Note the position of the optional AGP slot shown previously in Figure 4.16. It is mounted on the motherboard itself, not on the riser card as with PCI or ISA slots. This location was necessary because AGP was developed well after the NLX form factor was introduced. Most NLX motherboards use chipset-integrated or motherboard-based video instead of a separate AGP card, but you must remove an AGP card installed in an NLX system before you can remove the motherboard for servicing. Also, the AGP card used in an NLX system must have a different form factor to enable it to clear the rear connector shield at the back of the NLX motherboard (see Figure 4.20).

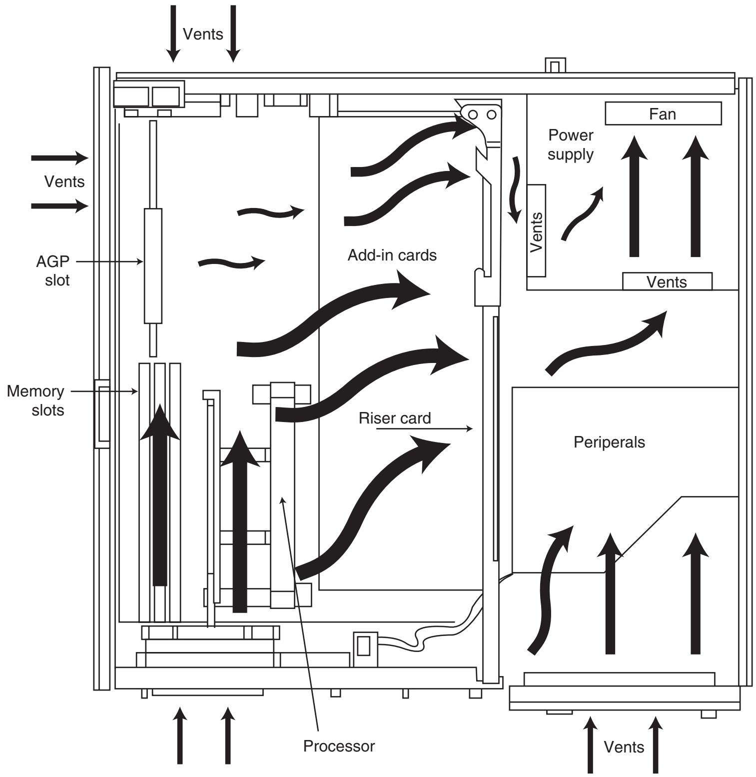

Figure 4.19 NLX system chassis layout and cooling airflow.

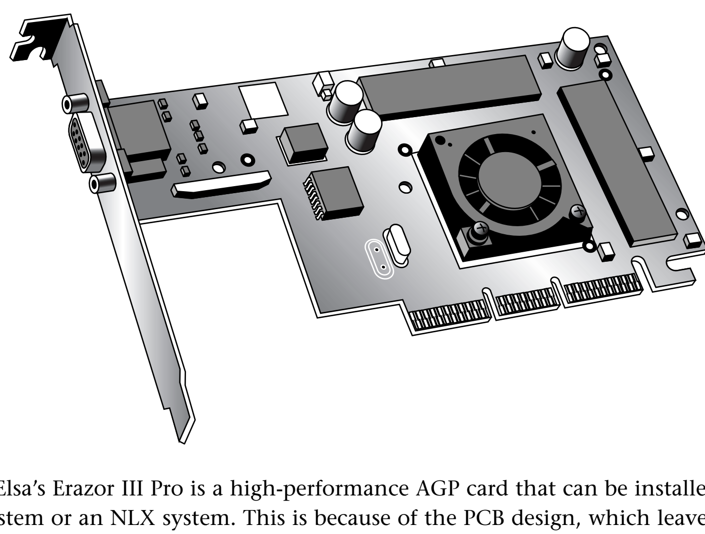

Figure 4.20 Elsa's Erazor III Pro is a high-performance AGP card that can be installed in either a standard ATX/Baby-AT system or an NLX system. This is because of the PCB design, which leaves room between the AGP port connector and the card's circuits for the NLX motherboard's rear connector shield. *Photo courtesy Elsa AG.*

The NLX motherboard is specified in three lengths, front to back: 13.6", 11.2", or 10" total (see Figure 4.21). With proper bracketry, the shorter boards can go into a case designed for a longer board.

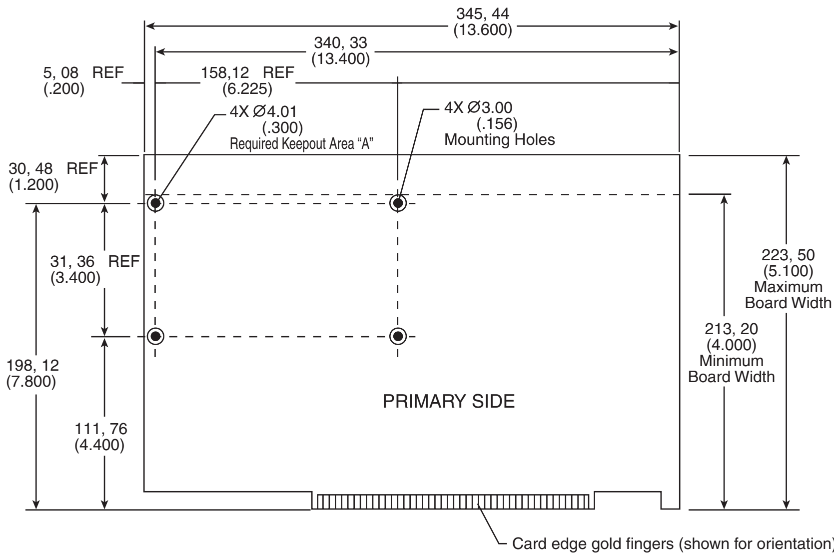

Figure 4.21 NLX form factor. This shows a 13.6" long NLX board. The NLX specification also allows shorter 11.2" and 10" versions.

As with most of the form factors, you can identify NLX via the unique I/O shield or connector area at the back of the board (see Figure 4.22). You only need a quick look at the rear of any given system to determine which type of board is contained within. Figure 4.22 shows the unique stepped design of the NLX I/O connector area. This allows for a row of connectors all along the bottom and has room for double-stacked connectors on one side.

As you can see, the NLX form factor has been designed for maximum flexibility and space efficiency. Even extremely long I/O cards will fit easily, without getting in the way of other system components—a problem with Baby-AT form factor systems.

The specification and related information about the NLX form factor are available through the Desktop Form Factor site located at `http://formfactors.org`. ATX, mini-ATX, micro-ATX, flex-ATX, and NLX form factors will be the predominant form factors used in virtually all future systems. Because these are well-defined standards that have achieved acceptance in the marketplace, I would avoid the older, obsolete standards, such as Baby-AT. I recommend avoiding LPX or other proprietary systems if upgradability is a factor because not only is locating a new motherboard that will fit difficult, but LPX systems are also limited in expansion slots and drive bays. Overall, ATX is still the best choice for most new systems where expandability, upgradability, low cost, and ease of service are of prime importance.

WTX

WTX was a board and system form factor developed for the mid-range workstation market; however, it didn't seem to catch on. WTX went beyond ATX and defined the size and shape of the board and the interface between the board and chassis, as well as required chassis features.

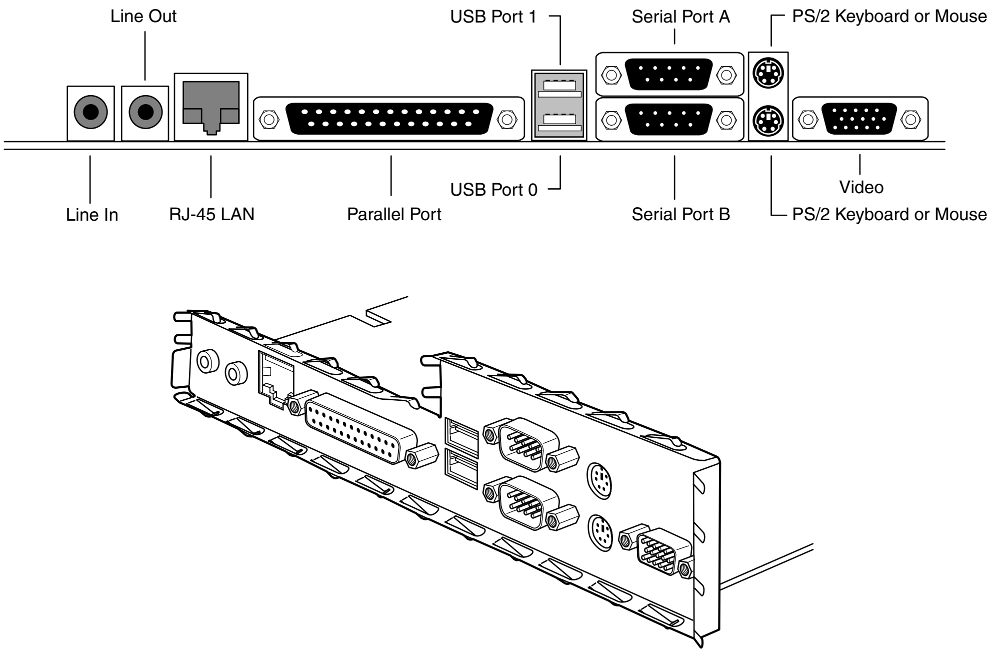

Figure 4.22 Typical NLX motherboard rear connector layout.

WTX was first released in September 1998 (1.0) and updated in February of 1999 (1.1). The specification and other information on WTX were available at the following Web site: `http://www.wtx.org`; however, they have been withdrawn and the site taken down. I am unsure whether it will be reintroduced later or whether something else will take its place in the future.

The very few WTX form factor systems that have been introduced were designed as servers. Figure 4.23 shows a typical WTX system with the cover removed. Note that easy access is provided to internal components via pull-out drawers and swinging side panels.

WTX motherboards have a maximum width of 14 inches (356mm) and a maximum length of 16.75 inches (425mm), which is significantly larger than ATX. There are no minimum dimensions, so board designers are free to design smaller boards as long as they meet the mounting criteria.

The WTX specification offers flexibility by leaving motherboard mounting features and locations undefined. Instead of defining exact screw hole positions, WTX motherboards must mount to a standard mounting adapter plate, which must be supplied with the board. The WTX chassis is designed to accept the mounting plate with attached motherboard and not just a bare board alone.

Note

For more information about WTX, see *Upgrading and Repairing PCs, 12th Edition*, available as a PDF on the CD-ROM included with this book.

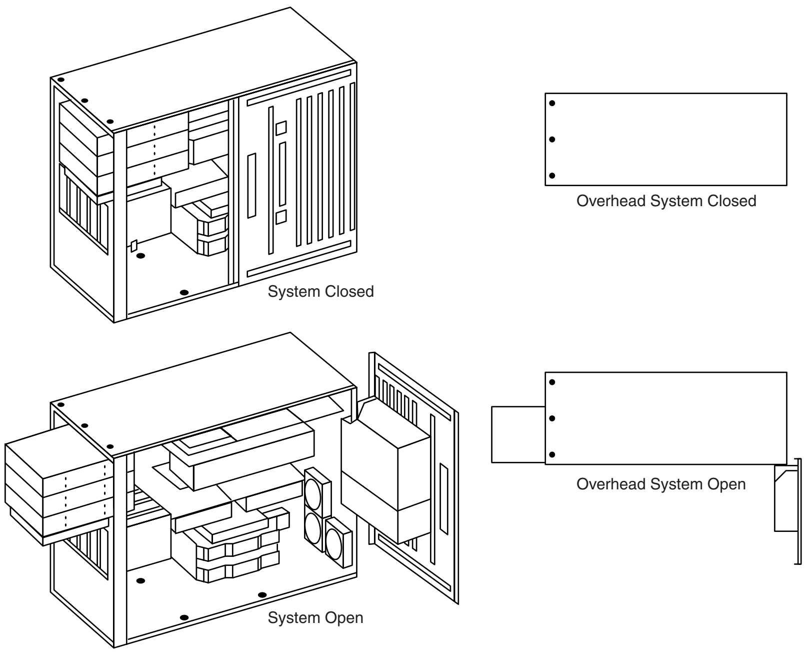

Figure 4.23 Typical WTX system chassis showing internal layout and ease of access.

Proprietary Designs

Motherboards that are *not* one of the standard form factors, such as full-size or Baby-AT, ATX, mini-ATX, micro-ATX, flex-ATX, or NLX, are deemed *proprietary*. LPX systems fall into this category. Most people purchasing PCs should avoid proprietary designs because they do not allow for a future motherboard, power supply, or case upgrade, which limits future use and serviceability of the system. To me, proprietary systems are disposable PCs because you can neither upgrade them nor easily repair them. The problem is that the proprietary parts can come only from the original system manufacturer, and they usually cost many times more than nonproprietary parts. Therefore, after your proprietary system goes out of warranty, not only is it not upgradable, but it is also essentially no longer worth repairing. If the motherboard or any component on it goes bad, you will be better off purchasing a completely new standard system than paying five times the normal price for a new proprietary motherboard. In addition, a new motherboard in a standard form factor system would be one or more generations newer and faster than the one you would be replacing. In a proprietary system, the replacement board would not only cost way too much, but it would be the same as the one that failed.

Note that you might be able to perform limited upgrades to older systems with proprietary motherboards, in the form of custom (non-OEM) processor replacements with attached voltage regulators, usually called “overdrive” or “turbo” chips. Unfortunately, these often don’t perform up to the standards of a less expensive new processor and motherboard combination. Of course, I usually recommend upgrading the motherboard and processor together—but that is something that can’t be done with a proprietary system.

The popular LPX motherboard design is at the heart of most proprietary systems. These systems are, or were, sold primarily in the retail store channel. This class of system has traditionally been dominated by Compaq (although some of the recent systems are now using industry-standard form factors), Hewlett- Packard (Vectra line), and formerly Packard Bell (no longer in business). As such, virtually all their systems have the problems inherent with their proprietary designs.

If the motherboard in your current ATX form factor system (and any system using a Baby-AT motherboard and case) dies, you can find any number of replacement boards that will bolt directly in—with your choice of processors and clock speeds—at great prices. If the motherboard dies in a proprietary form factor system, you'll pay for a replacement available only from the original manufacturer, and you have little or no opportunity to select a board with a faster or better processor than the one that failed. In other words, upgrading or repairing one of these systems via a motherboard replacement is difficult and usually not cost-effective.

Systems sold by the leading mail-order suppliers, such as Gateway, Micron, Dell, and others, are available in industry-standard form factors such as ATX, micro-ATX, and NLX. This allows for easy upgrading and system expansion in the future. These standard factors allow you to replace your own motherboards, power supplies, and other components easily and select components from any number of suppliers other than where you originally bought the system.

Backplane Systems

One type of proprietary design is the *backplane system*. These systems do not have a motherboard in the true sense of the word. In a backplane system, the components normally found on a motherboard are located instead on an expansion adapter card plugged into a slot.

In these systems, the board with the slots is called a backplane, rather than a motherboard. Systems using this type of construction are called backplane systems.

Backplane systems come in two main types—passive and active. A *passive* backplane means the main backplane board does not contain any circuitry at all except for the bus connectors and maybe some buffer and driver circuits. All the circuitry found on a conventional motherboard is contained on one or more expansion cards installed in slots on the backplane. Some backplane systems use a passive design that incorporates the entire system circuitry into a single mothercard. The mothercard is essentially a complete motherboard designed to plug into a slot in the passive backplane. The passive backplane/mothercard concept enables the entire system to be easily upgraded by changing one or more cards. Because of the expense of the high-function mothercard, this type of system design is rarely found in standard PC systems today, although it was once favored by a few early 286/386 vendors such as Zenith Data Systems. The passive backplane design does enjoy popularity in industrial systems, which are often rack-mounted. Some high-end fileservers also feature this design. Figure 4.24 shows a typical Pentium II single-board computer used in passive backplane systems. Figure 4.25 shows a rack-mount chassis with a passive backplane.

Passive backplane systems with mothercards (often called single-board computers) are by far the most popular backplane design. They are used in industrial or laboratory-type systems and are normally rack-mountable. They usually have a large number of slots and extremely heavy-duty power supplies; they also feature high-capacity, reverse flow cooling designed to pressurize the chassis with cool, filtered air. Many passive backplane systems, such as the one pictured in Figure 4.25, adhere to the PCI/ISA passive backplane and CompactPCI form factor standards set forth by the PCI Industrial Computer Manufacturers Group (PICMG). You can get more information about these standards from PICMG's Web site at `www.picmg.org`.

An *active* backplane means the main backplane board contains bus control and usually other circuitry as well. Most active backplane systems contain all the circuitry found on a typical motherboard except for what is then called the *processor complex*. The processor complex is the name of the circuit board that contains the main system processor and any other circuitry directly related to it, such as clock control, cache, and so forth. The processor complex design enables the user to easily upgrade the system later to a new processor type by changing one card. In effect, it amounts to a modular motherboard with a replaceable processor section.

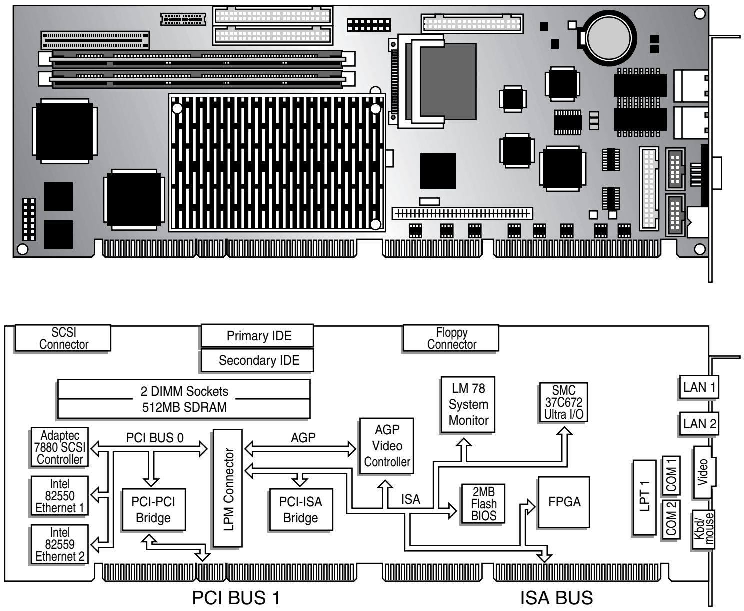

Figure 4.24 A typical Pentium IIPICMG single-board computer (top) and its major components (bottom). This single card provides PCI and ISA interfacing, AGP video, two Ethernet network interfaces, and a 68-pin Wide SCSI interface, as well as normal parallel, serial, IDE, and floppy interfaces.

Many large PC manufacturers have built systems with an active backplane/processor complex. Both IBM and Compaq, for example, have used this type of design in some of their high-end (server class) systems. ALR once made a series of desktop and server PCs that also featured this design. This allows an easier and generally more affordable upgrade than the passive backplane/mothercard design because the processor complex board is usually much cheaper than a mothercard. Unfortunately, because no standards exist for the processor complex interface to the system, these boards are proprietary and can be purchased only from the system manufacturer. This limited market and availability causes the prices of these boards to be higher than most complete motherboards from other manufacturers.

The motherboard system design and the backplane system design have advantages and disadvantages. Most original PCs were designed as backplanes in the late 1970s. Apple and IBM shifted the market to the now traditional motherboard with a slot-type design because this kind of system generally is cheaper to mass-produce than one with the backplane design. The theoretical advantage of a backplane system, however, is that you can upgrade it easily to a new processor and level of performance by changing a single card. For example, you can upgrade a system's processor just by changing the card. In a motherboard-design system, you often must change the motherboard, a seemingly more formidable task. Unfortunately, the reality of the situation is that a backplane design is often much more expensive to upgrade. For example, because the bus remains fixed on the backplane, the backplane design precludes more comprehensive upgrades that involve adding local bus slots.

Another nail in the coffin of backplane designs is the upgradable processor. Starting with the 486, Intel and AMD began standardizing the sockets or slots in which processors were to be installed, allowing a single motherboard to support a wider variety of processors and system speeds. Because board designs could be made more flexible, changing only the processor chip for a faster standard OEM type (not one of the kludgy "overdrive" chips) is the easiest and most cost-effective way to upgrade without changing the entire motherboard.

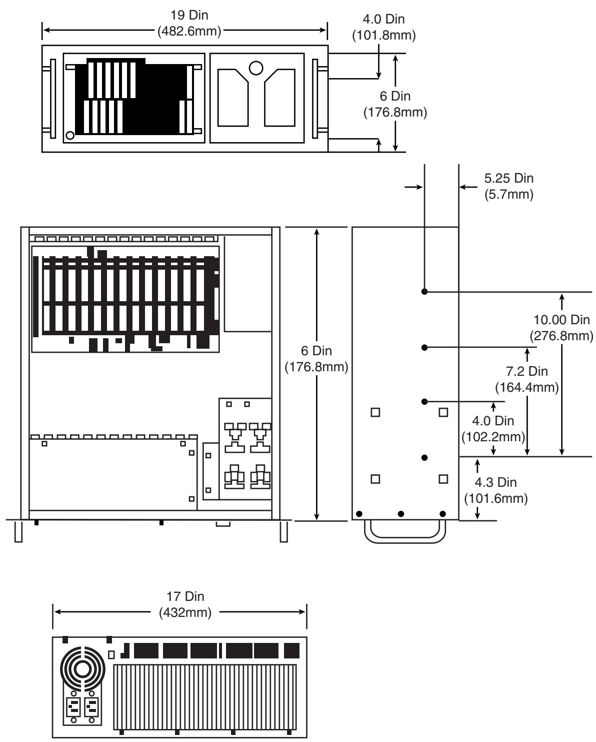

Figure 4.25 A rack-mount chassis with passive backplane.

Because of the limited availability of the processor-complex boards or mothercards, they usually end up being more expensive than a complete new motherboard that uses an industry-standard form factor. The bottom line is that unless you have a requirement for a large capacity industrial or laboratory-type system, especially one that would be rack-mounted, you are better off sticking with standard ATX form factor PCs. They will certainly be far less expensive.

Note

Some companies offer plug-in processor cards that essentially turn your existing motherboard into an active backplane, shutting down the main CPU and memory and having the card's processor and memory essentially take over. These are unfortunately much more expensive than a new motherboard and processor alone, normally use the more expensive SO-DIMM memory, don't provide AGP video, and are generally not recommended.

Motherboard Components

A modern motherboard has several components built in, including various sockets, slots, connectors, chips, and so on. This section examines the components found on a typical motherboard.

Most modern motherboards have at least the following major components on them:

- Processor socket/slot
- Chipset (North/South Bridge or memory and I/O controller hubs)
- Super I/O chip

- ROM BIOS (Flash ROM/firmware hub)
- SIMM/DIMM/RIMM (RAM memory) sockets
- ISA/PCI/AGP bus slots
- CPU voltage regulator
- Battery

Some motherboards also include integrated video, audio, networking, SCSI, Audio Modem Riser (AMR), Communications and Networking Riser (CNR) connectors, or other optional interfaces, depending on the individual board.

These standard components are discussed in the following sections.

Processor Sockets/Slots

The CPU is installed in either a socket or a slot, depending on the type of chip.

Starting with the 486 processors, Intel designed the processor to be a user-installable and replaceable part and developed standards for CPU sockets and slots that would allow different models of the same basic processor to plug in. These specifications were given a designation that is usually imprinted or embossed on the connector or board. After you know the type of socket or slot on your motherboard, you essentially know which type of processors are designed to plug in.

◄◄ See "Processor Sockets and Slots," 82.

Sockets for processors prior to the 486 were not designated, and interchangeability was limited. Table 4.3 shows the designations for the various processor sockets/slots and lists the chips designed to plug into them.

Table 4.3 CPU Socket Specifications

Number Socket	Pin	Pin Layout	Voltage	Supported Processors
Socket 1	169	17×17 PGA	5V	486 SX/SX2, DX/DX2[1], DX4 OD
Socket 2	238	19×19 PGA	5V	486 SX/SX2, DX/DX2[1], DX4 OD, 486 Pentium OD
Socket 3	237	19×19 PGA	5V/3.3V	486 SX/SX2, DX/DX2, DX4, 486 Pentium OD, 5x86
Socket 4	273	21×21 PGA	5V	Pentium 60/66, OD
Socket 5	320	37×37 SPGA	3.3V/3.5V	Pentium 75-133, OD
Socket 6[2]	235	19×19 PGA	3.3V	486 DX4, 486 Pentium OD
Socket 7	321	37×37 SPGA	VRM	Pentium 75-266+, MMX, OD, 6x86, K6
Socket 8	387	Dual-pattern SPGA	Auto VRM	Pentium Pro
Socket 370 (PGA370)	370	37×37 SPGA	Auto VRM	PIII/Celeron PPGA/FCPGA
Socket PAC418	418	38×22 split SPGA	Auto VRM	Itanium PAC
Socket 423 (PGA423)	423	39×39 SPGA	Auto VRM	Pentium 4
Socket A (PGA462)	462	37×37 SPGA	Auto VRM	Athlon/Duron PGA
Socket 603	603	31×25 SPGA	Auto VRM	Xeon (P4)

Table 4.3 Continued

Number Socket	Pin	Pin Layout	Voltage	Supported Processors
Slot 1 (SC242)	242	Keyed Slot	Auto VRM	PII, PIII/Celeron SECC
Slot A	242	Keyed Slot	Auto VRM	Athlon SECC
Slot 2 (SC330)	330	Keyed Slot	Auto VRM	PII Xeon, PIII Xeon

1. Non-OverDrive DX4 also can be supported with the addition of an aftermarket 3.3v voltage regulator adapter.

2. Socket 6 was a proposed standard only and was never actually implemented in any systems.

OD = OverDrive (retail upgrade processors).

PGA = Pin grid array.

SPGA = Staggered pin grid array.

PPGA = Plastic pin grid array.

FCPGA = Flip-Chip pppin grid array.

PAC = Pin array cartridge.

VRM = Voltage regulator module with variable voltage output determined by module or manual jumpers.

Auto-VRM = Voltage regulator module with automatic voltage selection determined by processor VID pins.

SECC = Single edge contact cartridge.

SC242 = Slot connector, 242 pins.

SC330 = Slot connector, 330 pins.

Originally, all processors were mounted in sockets (or soldered directly to the motherboard). With the advent of the Pentium II and original Athlon processors, both Intel and AMD shifted to a slot-based approach for their processors because the processors now incorporated built-in L2 cache, purchased as separate chips from third-party Static RAM (SRAM) memory chip manufacturers. Therefore, the processor then consisted not of one but of several chips, all mounted on a daughterboard that was then plugged into a slot in the motherboard. This worked well, but there were additional expenses in the extra cache chips, the daughterboard itself, the slot, optional casings or packaging, and the support mechanisms and physical stands and latches for the processor and heatsink. All in all, slot-based processors were expensive to produce compared to the previous socketed versions.

With the advent of the second-generation Celeron, Intel integrated the L2 cache directly into the processor die, meaning within the main CPU chip circuits, with no extra chips required. The second-generation (codenamed Coppermine) Pentium III also received on-die L2 cache, as did the K6-3, Duron (codenamed Spitfire), and second-generation Athlon (codenamed Thunderbird) processors from AMD (some early Thunderbird Athlon CPUs were also made in the Slot A configuration). With on-die L2, the processor was back to being a single chip again, which also meant that mounting it on a separate board plugged into a slot was expensive and unnecessary. Because of on-die integrated L2 cache, the trend for processor packaging has shifted back to sockets and will likely continue that way for the foreseeable future. All modern processors now use the socket form. Besides allowing a return to socketed packaging, the on-die L2 cache runs at full processor speed, instead of the one-half or one-third speed of the previous integrated (but not on-die) L2 cache.

The Itanium features a cartridge design that includes L3 cache, and yet plugs into a socket rather than a slot.

Chipsets

We cannot talk about modern motherboards without discussing chipsets. The chipset *is* the motherboard; therefore, any two boards with the same chipsets are functionally identical. The chipset contains the processor bus interface (called front-side bus, or FSB), memory controllers, bus controllers, I/O controllers, and more. All the circuits of the motherboard are contained within the chipset. If the processor in your PC is like the engine in your car, the chipset represents the chassis. It is the framework in which the engine rests and its connection to the outside world. The chipset is the frame, suspension, steering, wheels and tires, transmission, driveshaft, differential, and brakes. The chassis in your car is what gets the power to the ground, allowing the vehicle to start, stop, and corner. In the PC, the chipset represents the connection between the processor and everything else. The processor cannot talk to the memory, adapter boards, devices, and so on without going through the chipset. The chipset is the main hub and central nervous system of the PC. If you think of the processor as the brain, the chipset is the spine and central nervous system.

Because the chipset controls the interface or connections between the processor and everything else, the chipset ends up dictating which type of processor you have; how fast it will run; how fast the buses will run; the speed, type, and amount of memory you can use; and more. In fact, the chipset might be the single most important component in your system, possibly even more important than the processor. I've seen systems with faster processors be outperformed by systems with slower processor but a better chipset, much like how a car with less power might win a race through better cornering and braking. When deciding on a system, I start by choosing the chipset first because the chipset decision then dictates the processor, memory, I/O, and expansion capabilities.

Chipset Evolution

When IBM created the first PC motherboards, it used several discrete (separate) chips to complete the design. Besides the processor and optional math coprocessor, many other components were required to complete the system. These other components included items such as the clock generator, bus controller, system timer, interrupt and DMA controllers, CMOS RAM and clock, and keyboard controller. Additionally, a number of other simple logic chips were used to complete the entire motherboard circuit, plus, of course, things such as the actual processor, math coprocessor (floating-point unit), memory, and other parts. Table 4.4 lists all the primary chip components used on the original PC/XT and AT motherboards.

Table 4.4 Primary Chip Components on PC/XT and AT Motherboards

Chip Function	PC/XT Version	AT Version
Processor	8088	80286
Math Coprocessor (Floating-Point Unit	8087	80287
Clock Generator	8284	82284
Bus Controller	8288	82288
System Timer	8253	8254
Low-order Interrupt Controller	8259	8259
High-order Interrupt Controller	—	8259
Low-order DMA Controller	8237	8237
High-order DMA Controller	—	8237
CMOS RAM/Real-Time Clock	—	MC146818
Keyboard Controller	8255	8042

In addition to the processor/coprocessor, a six-chip set was used to implement the primary motherboard circuit in the original PC and XT systems. IBM later upgraded this to a nine-chip design in the AT and later systems, mainly by adding additional interrupt and DMA controller chips and the nonvolatile CMOS RAM/Real-time Clock chip. All these motherboard chip components came from Intel or an Intel-licensed manufacturer, except the CMOS/Clock chip, which came from Motorola. To build a clone or copy of one of these IBM systems required all these chips plus many smaller discrete logic chips to glue the design together, totaling 100 or more individual chips. This kept the price of a motherboard high and left little room on the board to integrate other functions.

In 1986, a company called Chips and Technologies introduced a revolutionary component called the 82C206—the main part of the first PC motherboard chipset. This was a single chip that integrated into it all the functions of the main motherboard chips in an AT-compatible system. This chip included the functions of the 82284 Clock Generator, 82288 Bus Controller, 8254 System Timer, dual 8259 Interrupt Controllers, dual 8237 DMA Controllers, and even the MC146818 CMOS/Clock chip. Besides the processor, virtually all the major chip components on a PC motherboard could now be replaced by a single chip. Four other chips augmented the 82C206 acting as buffers and memory controllers, thus completing virtually the entire motherboard circuit with five total chips. This first chipset was called the CS8220 chipset by Chips and Technologies. Needless to say, this was a revolutionary concept in PC motherboard manufacturing. Not only did it greatly reduce the cost of building a PC motherboard, but it also made designing a motherboard much easier. The reduced component count meant the boards had more room for integrating other items formerly found on expansion cards. Later, the four chips augmenting the 82C206 were replaced by a new set of only three chips, and the entire set was called the New Enhanced AT (NEAT) CS8221 chipset. This was later followed by the 82C836 Single Chip AT (SCAT) chipset, which finally condensed all the chips in the set down to a single chip.

The chipset idea was rapidly copied by other chip manufacturers. Companies such as Acer, Erso, Opti, Suntac, Symphony, UMC, and VLSI each gained an important share of this market. Unfortunately, for many of them, the chipset market has been a volatile one, and many of them have long since gone out of business. In 1993, VLSI had become the dominant force in the chipset market and had the vast majority of the market share; by the next year, VLSI (which later was merged into Philips Semiconductors), along with virtually everybody else in the chipset market, were fighting to stay alive. This is because a new chipset manufacturer had come on the scene, and within a year or so of getting serious, it was totally dominating the chipset market. That company was Intel, and after 1994 it had a virtual lock on the chipset market. If you have a motherboard built since 1994 that uses or accepts an Intel processor, chances are good that it has an Intel chipset on it as well.

More recently, Intel has struggled somewhat with chipsets because of its reliance on RDRAM memory. Intel signed a contract with Rambus back in 1996 declaring it would support this memory as its primary focus for desktop PC chipsets through 2001. I suspect this has turned out to be something Intel regrets. RDRAM memory has a significantly higher price than SDRAM memory and doesn't seem to have any significant performance advantages. In fact, it is slower than the double data rate (DDR) SDRAM the mainstream has decided to support. Consequently, Intel is developing a DDR SDRAM chipset codenamed Brookdale for release in late 2001 or early 2002.

A few chipset manufacturers have carved out a niche supporting AMD processors. Today, that would include primarily Acer Laboratories, Inc. (ALi), VIA Technologies, and Silicon integrated Systems (SiS). Along with AMD's own chipsets, these companies have products that support the AMD Athlon and Duron processors, and previously the AMD K6 as well. Currently, VIA and AMD seem to dominate the Athlon/Duron chipset market.

It is interesting to note that Chips and Technologies survived by changing course to design and manufacture video chips and found a niche in that market specifically for laptop and notebook video chipsets. Chips and Technologies was subsequently bought out by Intel in 1998 as a part of Intel's video strategy.

Intel Chipsets

You cannot talk about chipsets today without discussing Intel because it currently owns the vast majority of the chipset market. It is interesting to note that we probably have Compaq to thank for forcing Intel into the chipset business in the first place!

The thing that really started it all was the introduction of the EISA bus designed by Compaq in 1989. At that time, it had shared the bus with other manufacturers in an attempt to make it a market standard. However, it refused to share its EISA bus chipset—a set of custom chips necessary to implement this bus on a motherboard.

Enter Intel, who decided to fill the chipset void for the rest of the PC manufacturers wanting to build EISA bus motherboards. As is well known today, the EISA bus failed to become a market success except for a short-term niche server business, but Intel now had a taste of the chipset business and this it apparently wouldn't forget. With the introduction of the 286 and 386 processors, Intel became impatient with how long it took the other chipset companies to create chipsets around its new processor designs; this delayed the introduction of motherboards that supported the new processors. For example, it took more than two years after the 286 processor was introduced for the first 286 motherboards to appear and just over a year for the first 386 motherboards to appear after the 386 had been introduced. Intel couldn't sell its processors in volume until other manufacturers made motherboards that would support them, so it thought that by developing motherboard chipsets for a new processor in parallel with the new processor, it could jumpstart the motherboard business by providing ready-made chipsets for the motherboard manufacturers to use.

Intel tested this by introducing the 420 series chipsets along with its 486 processor in April of 1989. This enabled the motherboard companies to get busy right away, and it was only a few months before the first 486 motherboards appeared. Of course, the other chipset manufacturers weren't happy; now they had Intel as a competitor, and Intel would always have chipsets for new processors on the market first!

Intel then realized that it now made both processors *and* chipsets, which were 90% of the components on a typical motherboard. What better way to ensure that motherboards were available for its Pentium processor when it was introduced than by making its own motherboards as well and having these boards ready on the new processor's introduction date. When the first Pentium processor debuted in 1993, Intel also debuted the 430LX chipset and a fully finished motherboard as well. Now, not only were the chipset companies upset, but the motherboard companies weren't too happy either. Intel was not only the major supplier of parts needed to build finished boards (processors and chipsets), but Intel was now building and selling the finished boards as well. By 1994, Intel had not only dominated the processor and chipset markets, but it had cornered the motherboard market as well.

Now as Intel develops new processors, it develops chipsets and motherboards simultaneously, which means they can be announced and shipped in unison. This eliminates the delay between introducing new processors and waiting for motherboards and systems capable of using them, which was common in the industry's early days. For the consumer, this means no waiting for new systems. Since the original Pentium processor in 1993, we have been able to purchase ready-made systems on the same day a new processor is released.

In my seminars, I ask how many people in the class have Intel brand PCs. Of course, Intel does not sell or market a PC under its own name, so nobody thinks they have an "Intel brand" PC. But, if your motherboard was made by Intel, for all intents and purposes you sure seem to have an Intel brand PC, at least as far as the components are concerned. Does it really matter whether Dell, Gateway, or Micron put that same Intel motherboard into a slightly different looking case with their name on it?

If you look under the covers, you'll find that many, if not most, of the systems from the major manufacturers are really the same because they use basically the same parts. Although more and more major manufacturers are offering AMD Athlon- and Duron-based systems as alternatives to Intel's, no manufacturer dominates AMD motherboard sales the way Intel has dominated OEM sales to major system manufacturers.

To hold down pricing, many low-cost retail systems based on micro-ATX motherboards use non-Intel motherboards. But, even though many companies make Intel-compatible motherboards for aftermarket upgrades or local computer assemblers, Intel still dominates the major vendor OEM market for midrange and high-end systems.

Intel Chipset Model Numbers

Intel started a pattern of numbering its chipsets as follows:

Chipset Number	Processor Family
420xx	P4 (486)
430xx	P5 (Pentium)
440xx	P6 (Pentium Pro/PII/PIII)
8xx	P6 (PII/PIII/P4) with hub architecture
450xx	P6 Server (Pentium Pro/PII/PIII Xeon)

The chipset numbers listed here are an abbreviation of the actual chipset numbers stamped on the individual chips. For example, one of the popular Pentium II/III chipsets is the Intel 440BX chipset, which really consists of two components, the 82443BX North Bridge and the 82371EX South Bridge. Likewise, the 850 chipset supports the Pentium 4 and consists of two main parts, including the 82850 Memory Controller Hub (MCH) and an 82801BA I/O Controller Hub (ICH2). By reading the logo (Intel or others) as well as the part number and letter combinations on the larger chips on your motherboard, you can quickly identify the chipset your motherboard uses.

Intel has used two distinct chipset architectures: a North/South Bridge architecture and a newer hub architecture. All its more recent 800 series chipsets use the hub architecture.

AMD Athlon/Duron Chipsets

AMD took a gamble with its Athlon and Duron processors. With these processors, AMD decided for the first time to create a chip that was Intel-compatible with regards to software but not directly hardware or pin compatible. Whereas the K6 series would plug into the same Socket 7 that Intel designed for the Pentium processor line, the AMD Athlon and Duron would not be pin compatible with the Pentium II/III and Celeron chips. This also meant that AMD could not take advantage of the previously existing chipsets and motherboards when the Athlon and Duron were introduced; instead, AMD would have to either create its own chipsets and motherboards or find other companies who would.

The gamble seems to have paid off. AMD bootstrapped the market by introducing its own chipset, referred to as the AMD-750 chipset and codenamed Irongate. The AMD 750 chipset consists of the 751 System Controller (North Bridge) and the 756 Peripheral Bus Controller (South Bridge). More recently, AMD introduced the AMD-760 chipset for the Athlon/Duron processors, which is the first major chipset on the market supporting DDR SDRAM for memory. It consists of two chips—the AMD-761 System Bus Controller (North Bridge) and the AMD-766 Peripheral Bus Controller (South Bridge). Other companies, such as VIA Technologies and SiS, have also introduced chipsets specifically designed for the Socket/Slot A processors from AMD. This enabled the motherboard companies to make a variety of boards supporting these chips and the Athlon and Duron processors to take a fair amount of market share away from Intel in the process.

North/South Bridge Architecture

Most of Intel's earlier chipsets (and virtually all non-Intel chipsets) are broken into a multi-tiered architecture incorporating what are referred to as North and South Bridge components, as well as a Super I/O chip:

- *The North Bridge.* So named because it is the connection between the high-speed processor bus (400/266/200/133/100/66MHz) and the slower AGP (533/266/133/66MHz) and PCI (33MHz) buses. The North Bridge is what the chipset is named after, meaning that, for example, what we call the 440BX chipset is actually derived from the fact that the actual North Bridge chip part number for that set is 82443BX.
- *The South Bridge.* So named because it is the bridge between the PCI bus (66/33MHz) and the even slower ISA bus (8MHz).
- *The Super I/O chip.* It's a separate chip attached to the ISA bus that is not really considered part of the chipset and often comes from a third party, such as National Semiconductor or Standard MicroSystems Corp. (SMSC). The Super I/O chip contains commonly used peripheral items all combined into a single chip.

▶▶ See "Super I/O Chips," p. 283.

Chipsets have evolved over the years to support various processors, bus speeds, peripheral connections, and features.

Figure 4.26 shows a typical AMD Socket A motherboard using North/South Bridge architecture with the locations of all chips and components.

The North Bridge is sometimes referred to as the PAC (PCI/AGP Controller). It is essentially the main component of the motherboard and is the only motherboard circuit besides the processor that normally runs at full motherboard (processor bus) speed. Most modern chipsets use a single-chip North Bridge; however, some of the older ones actually consisted of up to three individual chips to make up the complete North Bridge circuit.

The South Bridge is the lower-speed component in the chipset and has always been a single individual chip. The South Bridge is a somewhat interchangeable component in that different chipsets (North Bridge chips) often are designed to use the same South Bridge component. This modular design of the chipset allows for lower cost and greater flexibility for motherboard manufacturers. The South Bridge connects to the 33MHz PCI bus and contains the interface or bridge to the 8MHz ISA bus. It also normally contains dual IDE hard disk controller interfaces, one or two USB interfaces, and in later designs even the CMOS RAM and real-time clock functions. The South Bridge contains all the components that make up the ISA bus, including the interrupt and DMA controllers.

The third motherboard component, the Super I/O chip, is connected to the 8MHz ISA bus and contains all the standard peripherals that are built in to a motherboard. For example, most Super I/O chips contain the serial ports, parallel port, floppy controller, and keyboard/mouse interface. Optionally, they also might contain the CMOS RAM/Clock, IDE controllers, and game port interface as well. Systems that integrate IEEE-1394 and SCSI ports use separate chips for these port types.

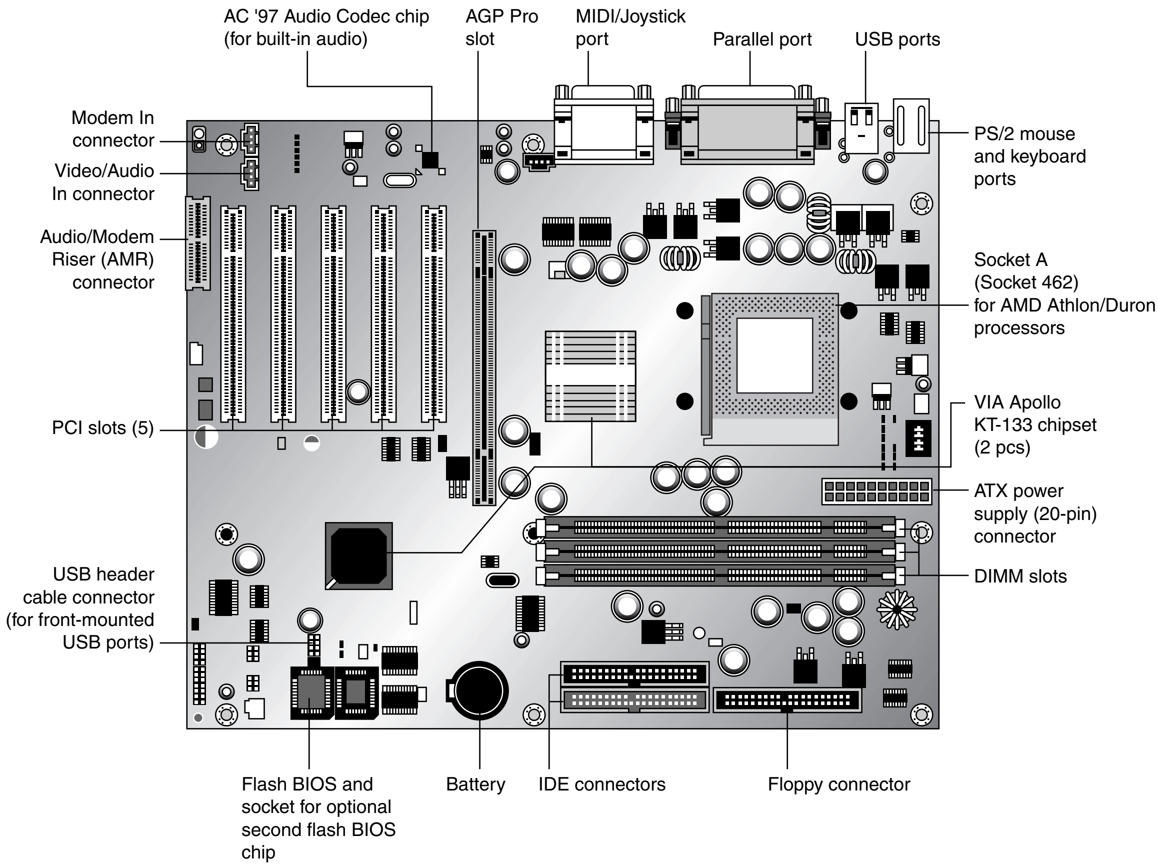

Figure 4.26 A typical Socket A (AMD Athlon/Duron) motherboard showing component locations.

Hub Architecture

The newer 800 series chips use a hub architecture in which the former North Bridge chip is now called a Memory Controller Hub (MCH), and the former South Bridge is called an I/O Controller Hub (ICH). Rather than connect them through the PCI bus as in a standard North/South Bridge design, they are connected via a dedicated hub interface that is twice as fast as PCI. The hub design offers several advantages over the conventional North/South Bridge design:

- *It's faster.* The hub interface is a 4X (quad-clocked) 66MHz 8-bit (4 × 66MHz × 1 Byte = 266MB/sec) interface, which has twice the throughput of PCI (33MHz × 32-bit = 133MB/sec).
- *Reduced PCI loading.* The hub interface is independent of PCI and doesn't share or steal PCI bus bandwidth for chipset or Super I/O traffic. This improves performance of all other PCI bus connected devices because the PCI bus is not involved in these transactions.
- *Reduced board wiring.* Although twice as fast as PCI, the hub interface is only 8 bits wide and requires only 15 signals to be routed on the motherboard. By comparison, PCI requires no less than 64 signals be routed on the board, causing increased electro-magnetic interference (EMI) generation, greater susceptibility to signal degradation and noise, and increased board manufacturing costs.

This hub interface design allows for a much greater throughput for PCI devices because there is no South Bridge chip (also carrying traffic from the Super I/O chip) hogging the PCI bus. Due to bypassing PCI, hub architecture also enables greater throughput for devices directly connected to the I/O Controller Hub (formerly the South Bridge), such as the new higher-speed ATA-100 and USB 2.0 interfaces.

The hub interface design is also very economical, being only 8 bits wide. Although this seems too narrow to be useful, there is a reason for the design. By making the interface only 8 bits wide, it uses only 15 signals, compared to the 64 signals required by the 32-bit-wide PCI bus interface used by North/South Bridge chip designs. The lower pin count means less circuit routing exists on the board, less signal noise and jitter occur, and the chips themselves have many fewer pins, making them smaller and more economical to produce.

Although it transfers only 8 bits at a time, the hub interface does four transfers per cycle and cycles at 66MHz. This gives it an effective throughput of 4 × 66MHz × 1 byte = 266MB/second. This is twice the bandwidth of PCI, which is 32 bits wide but runs only one transfer per 33MHz cycles for a total bandwidth of 133MB/second. So by virtue of a very narrow—but very fast—design, the hub interface achieves high performance with less cost and more signal integrity than with the previous North/South Bridge design.

The MCH interfaces between the high-speed processor bus (400/133/100/66MHz) and the hub interface (66MHz) and AGP bus (533/266/133/66MHz), whereas the ICH interfaces between the hub interface (66MHz) and the ATA(IDE) ports (66/100MHz) and PCI bus (33MHz).

The ICH also includes a new low-pin-count (LPC) bus, consisting basically of a stripped 4-bit wide version of PCI designed primarily to support the motherboard ROM BIOS and Super I/O chips. By using the same four signals for data, address, and command functions, only nine other signals are necessary to implement the bus, for a total of only thirteen signals. This dramatically reduces the number of traces connecting the ROM BIOS chip and Super I/O chips in a system as compared to the ninety-six ISA bus signals necessary for older North/South Bridge chipsets that used ISA as the interface to those devices. The LPC bus has a maximum bandwidth of 6.67MB/sec, which is close to ISA and more than enough to support devices such as ROM BIOS and Super I/O chips.

Figure 4.27 shows a typical Intel motherboard that uses bus architecture—the Intel DB850GB, which supports the Intel Pentium 4 processor. Unlike some of Intel's less-expensive hub-based motherboards, the DB850GB's Intel 850 chipset doesn't incorporate video.

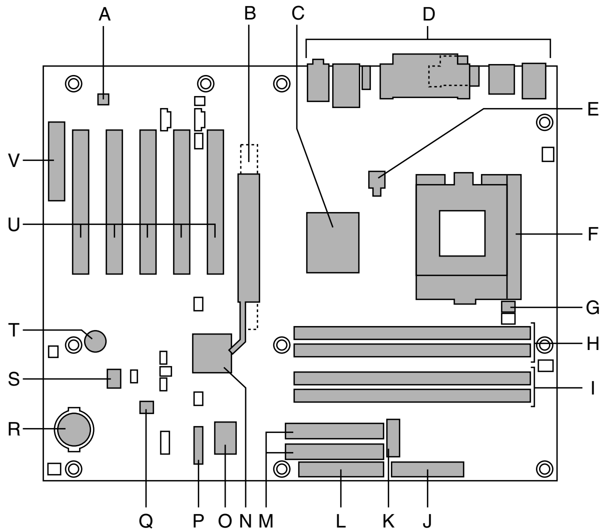
Let's examine the popular chipsets, starting with those used in 486 motherboards and working all the way through to the latest Pentium III/Celeron, Athlon/Duron, and VIA chipsets.

Intel's Early 386/486 Chipsets

Intel's first real PC motherboard chipset was the 82350 chipset for the 386DX and 486 processors. This chipset was not very successful, mainly because the EISA bus was not very popular and many other manufacturers were making standard 386 and 486 motherboard chipsets at the time. The market changed very quickly, and Intel dropped the EISA bus support and introduced follow-up 486 chipsets that were much more successful.

Table 4.5 shows the Intel 486 chipsets.

The 420 series chipsets were the first to introduce the North/South Bridge design that is still used in many chipsets today.



A AD1881/AD1885 audio codec (optional)
B AGP connector (AGP Pro 1.5V connector optional)
C Intel 82850 Memory Controller Hub (MCH)
D Back panel connectors
E +12V power connector (ATX 12V)
F Pentium 4 Processor socket
G Hardware monitor
H RAMBUS Bank 0 (RIMM1 and RIMM2)
I RAMBUS Bank 1 (RIMM3 and RIMM4)
J Power connector
K Auxiliary power connector
L Diskette drive connector
M IDE connectors
N Intel 82801BA I/O Controller Hub (ICH2)
O SMSC LPC47M102 I/O Controller
P Front panel connector
Q Enhanced thermal monitor and fan control device
R Battery
S SST 49LF004A 4Mbit Firmware Hub (FWH)
T Speaker
U PCI bus add-in card connectors
V Communication and Networking Riser (CNR) connector (optional)

Table 4.5 Intel 486 Motherboard Chipsets

Chipset	420TX	420EX	420ZX
Codename	Saturn	Aries	Saturn II
Date introduced	Nov. 1992	March 1994	March 1994
Processor	5v 486	5v/3.3v 486	5v/3.3v 486
Bus speed	up to 33MHz	up to 50MHz	up to 333MHz
SMP (dual CPUs)	No	No	No
Memory types	FPM	FPM	FPM
Parity/ECC	Parity	Parity	Parity
Max. memory	128MB	128MB	160MB
L2 cache type	Async	Async	Async
PCI support	2.0	2.0	2.1
AGP support	No	No	No

SMP = Symmetric multiprocessing (dual processors).
FPM = Fast page mode.
PCI = Peripheral component interconnect.
AGP = Accelerated graphics port.
Note: PCI 2.1 supports concurrent PCI operations.

Fifth-Generation (P5 Pentium Class) Chipsets

With the advent of the Pentium processor in March of 1993, Intel also introduced its first Pentium chipset, the 430LX chipset (codenamed Mercury). This was the first Pentium chipset on the market and set the stage as Intel took this lead and ran with it. Other manufacturers took months to a year or more to get their Pentium chipsets out the door. Since the debut of its Pentium chipsets, Intel has dominated the chipset market. Table 4.6 shows the Intel Pentium motherboard chipsets. Note that none of these chipsets support AGP; Intel supports AGP only in its chipsets for the Pentium II/Celeron and later processors.

Table 4.6 Intel Pentium Motherboard Chipsets (North Bridge)

Chipset	430LX	430NX	430FX	430MX	430HX	430VX	430TX
Codename	Mercury	Neptune	Triton	Mobile Triton	Triton II	Triton III	n/a
Date introduced	March 1993	March 1994	Jan. 1995	Oct. 1995	Feb. 1996	Feb. 1996	Feb. 1997
CPU bus speed	66MHz	66MHz	66MHz	66MHz	66MHz	66MHz	66MHz
CPUs supported	P60/66	P75+	P75+	P75+	P75+	P75+	P75+
SMP (dual CPUs)	No	Yes	No	No	Yes	No	No
Memory types	FPM	FPM	FPM/EDO	FPM/EDO	FPM/EDO	FPM/ EDO/ SDRAM	FPM/ EDO/ SDRAM
Parity/ECC	Parity	Parity	Neither	Neither	Both	Neither	Neither
Max. memory	192MB	512MB	128MB	128MB	512MB	128MB	256MB
Max. cacheable	192MB	512MB	64MB	64MB	512MB	64MB	64MB
L2 cache type	Async	Async	Async/ Pburst	Async/ Pburst	Async/ Pburst	Async/ Pburst	Async/ Pburst
PCI support	2.0	2.0	2.0	2.0	2.1	2.1	2.1
AGP support	No	No	No	No	No	No	No
South Bridge	SIO	SIO	PIIX	MPIIX	PIIX3	PIIX3	PIIX4

SMP = Symmetric multiprocessing (dual processors)
FPM = Fast page mode
EDO = Extended data out
SDRAM = Synchronous dynamic RAM
SIO = System I/O
PIIX = PCI ISA IDE Xcelerator

Note

PCI 2.1 supports concurrent PCI operations, enabling multiple PCI cards to perform transactions at the same time for greater speed.Bridge

Table 4.7 shows all the applicable Intel South Bridge chips, which are the second part of the modern Intel motherboard chipsets.

Table 4.7 Intel South Bridge Chips

Chip Name	SIO	PIIX	PIIX3	PIIX4	PIIX4E	ICH0	ICH
Part number	82378IB/ZB	82371FB	82371SB	82371AB	82371EB	82801AB	82801AA
IDE support	None	BMIDE	BMIDE	UDMA-33	UDMA-33	UDMA-33	UDMA-66
USB support	None	None	Yes	Yes	Yes	Yes	Yes
CMOS/clock	No	No	No	Yes	Yes	Yes	Yes
Power management	SMM	SMM	SMM	SMM	SMM/ ACPI	SMM/ ACPI	SMM/ ACPI

SIO = System I/O
PIIX = PCI ISA IDE Xcelerator
ICH = I/O Controller Hub
USB = Universal serial bus
IDE = Integrated Drive Electronics (AT attachment)
BMIDE = Bus master IDE
UDMA = Ultra-DMA IDE
SMM = System management mode
ACPI = Advanced configuration and power interface

The following sections detail all the Pentium motherboard chipsets and their specifications.

Intel 430LX (Mercury)

The 430LX was introduced in March of 1993, concurrent with the introduction of the first Pentium processors. This chipset was used only with the original Pentiums, which came in 60MHz and 66MHz versions. These were 5v chips and were used on motherboards with Socket 4 processor sockets.

◀◀ See "Processor Sockets and Slots," p. 82.

◀◀ See "First-Generation Pentium Processor," p. 133.

The 430LX chipset consisted of three total chips for the North Bridge portion. The main chip was the 82434LX system controller. This chip contained the processor-to-memory interface, cache controller, and PCI bus controller. There was also a pair of PCI bus interface accelerator chips, which were identical 82433LX chips.

The 430LX chipset was noted for the following:

- Single processor
- Support for up to 512KB of L2 cache
- Support for up to 192MB of standard DRAM

This chipset died off along with the 5v 60/66MHz Pentium processors.

Intel 430NX (Neptune)

Introduced in March 1994, the 430NX was the first chipset designed to run the new 3.3v second-generation Pentium processor. These were noted by having Socket 5 processor sockets and an onboard 3.3v/3.5v voltage regulator for both the processor and chipset. This chipset was designed primarily for Pentiums with speeds from 75MHz to 133MHz, although it was used mostly with 75MHz–100MHz systems. Along with the lower voltage processor, this chipset ran faster, cooler, and more reliably than the first-generation Pentium processor and the corresponding 5v chipsets.

◀◀ See "CPU Operating Voltages," p. 97.

◀◀ See "Second-Generation Pentium Processor," p. 133.

The 430NX chipset consisted of three chips for the North Bridge component. The primary chip was the 82434NX, which included the cache and main memory (DRAM) controller and the control interface to the PCI bus. The actual PCI data was managed by a pair of 82433NX chips called local bus accelerators. Together, these two chips, plus the main 82434NX chip, constituted the North Bridge.

The South Bridge used with the 430NX chipset was the 82378ZB System I/O (SIO) chip. This component connected to the PCI bus and generated the lower-speed ISA bus.

The 430NX chipset introduced the following improvements over the Mercury (430LX) chipset:

- Dual processor support
- Support for 512MB of system memory (up from 192MB for the LX Mercury chipset)

This chipset rapidly became the most popular chipset for the early 75MHz–100MHz systems, overshadowing the older 60MHz and 66MHz systems that used the 430LX chipset.

Intel 430FX (Triton)

The 430FX (Triton) chipset rapidly became popular after it was introduced in January 1995. This chipset is noted for being the first to support extended data out (EDO) memory, which subsequently became very popular. EDO was about 21% faster than the standard fast page mode (FPM) memory that had been used up until that time but cost no more than the slower FPM. Unfortunately, while being known for faster memory support, the Triton chipset was also known as the first Pentium chipset without support for parity checking for memory. This was somewhat of a blow to PC reliability and fault tolerance, although many did not know it at the time.

▶▶ See "Extended Data Out RAM," p. 416.

▶▶ See "Parity and ECC," p. 443.

The Triton chipset lacked not only parity support from the previous 430NX chipset, but it also would support only a single CPU. The 430FX was designed as a low-end chipset for home or non–mission-critical systems. As such, it did not replace the 430NX, which carried on in higher-end network fileservers and other more mission-critical systems.

The 430FX consisted of a three-chip North Bridge. The main chip was the 82437FX system controller that included the memory and cache controllers, CPU interface, and PCI bus controller, along with dual 82438FX data path chips for the PCI bus. The South Bridge was the first PIIX (PCI ISA IDE Xcelerator) chip that was the 82371FB. This chip acted not only as the bridge between the 33MHz PCI bus and the slower 8MHz ISA bus, but also incorporated for the first time a dual-channel IDE interface. By moving the IDE interface off the ISA bus and into the PIIX chip, it was now effectively connected to the PCI bus, enabling much faster Bus Master IDE transfers. This was key in supporting the ATA-2 or Enhanced IDE interface for better hard disk performance.

The major points on the 430FX are

- Support for EDO memory
- Support for higher speed—pipelined burst L2 cache
- PIIX South Bridge with high-speed Bus Master IDE
- Lack of support for parity-checked memory
- Only single CPU support
- Supported only 128MB of RAM, of which only 64MB could be cached

That last issue is one that many people are not aware of. The 430FX chipset can cache only up to 64MB of main memory. So, if you install more than 64MB of RAM in your system, performance suffers greatly. At the time, many didn't think this would be that much of a problem—after all, they didn't usually run enough software to load past the first 64MB anyway. That is another misunderstanding because Windows 9x and NT/2000 (as well as all other protected-mode operating systems including Linux and so on) load from the top down. So, for example, if you install 96MB of RAM (one 64MB and one 32MB bank), virtually all your software, including the main operating system, will be loading into the noncached region above 64MB. Needless to say, performance would suffer greatly. Try disabling the L2 cache via your CMOS Setup to see how slow your system runs without it. That is the performance you can expect if you install more than 64MB of RAM in a 430FX-based system.

Intel 430HX (Triton II)

Intel created the Triton II 430HX chipset as a true replacement for the powerful 430NX chip. It added some of the high-speed memory features from the low-end 430FX, such as support for EDO memory and pipeline burst L2 cache. It also retained dual-processor support. In addition to supporting parity checking to detect memory errors, it also added support for error correcting code (ECC) memory to detect and correct single bit errors on-the-fly. And the great thing was that this was implemented using plain parity memory.

The HX chipset's primary advantages over the FX are

- Symmetric multiprocessor (dual processor) support.
- Support for ECC and parity memory.
- 512MB maximum RAM support (versus 128MB).
- L2 cache functions over 512MB RAM versus 64MB (providing optional cache tag RAM is installed).
- Memory transfers in fewer cycles overall.
- PCI Level 2.1 compliance that allows concurrent PCI operations.
- PIIX3 supports different IDE/ATA transfer speed settings on a single channel.
- PIIX3 South Bridge component supports USB.

The memory problems with caching in the 430FX were corrected in the 430HX. This chipset allowed for the possibility of caching the full 512MB of possible RAM as long as the correct amount of cache *tag* was installed. Tag is a small cache memory chip used to store the index to the data in the cache. Most 430HX systems shipped with a tag chip that could manage only 64MB of cached main memory, although you could optionally upgrade it to a larger capacity tag chip that would allow for caching the full 512MB of RAM.

The 430HX chipset was a true one-chip North Bridge. It was also one of the first chips out in a ball-grid array (BGA) package, in which the chip leads are configured as balls on the bottom of the chip. This made possible a smaller chip package than the previous plastic quad flat pack (PQFP) packaging used on the older chips, and, because only one chip existed for the North Bridge, a very compact motherboard was possible. The South Bridge was the PIIX3 (82371SB) chip, which enabled independent timing of the dual IDE channels. Therefore, you could install two different speed devices on the same channel and configure their transfer speeds independently. Previous PIIX chips allowed both devices to work at the lowest common denominator speed supported by both. The PIIX3 also incorporated the USB for the first time on a PC motherboard. Unfortunately at the time, there were no devices available to attach to USB, nor was there any operating systems or driver support for the bus. USB ports were a curiosity at the time, and nobody had a use for them.

▶▶ See "Universal Serial Bus," p. 940.

The 430HX supports the newer PCI 2.1 standard, which allowed for concurrent PCI operations and greater performance. Combined with the support for EDO and pipelined burst cache, this was perhaps the best Pentium chipset for the power user's system. It offered not only excellent performance, but with ECC memory it offered a truly reliable and stable system design.

The 430HX was the only modern Intel Pentium-class chipset to offer parity and error-corrected memory support. This made it the recommended Intel chipset at the time for mission-critical applications, such as fileservers, database servers, business systems, and so on.

Intel 430VX (Triton III)

The 430VX was designed to be a replacement for the low-end 430FX chipset. It was not a replacement for the higher-powered 430HX chipset. As such, the VX has only one significant technical advantage over the HX, but in almost all other respects it is more like the 430FX than the HX.

The VX has the following features:

- Support for 66MHz SDRAM
- No parity or ECC memory support
- Single processor only
- Supports only 128MB RAM
- Supports caching for only 64MB RAM

Most notable was the support for SDRAM, which was about 27% faster than the more popular EDO memory used at the time. Although the support for SDRAM was a nice bonus, the actual improvement in system speed derived from such memory was somewhat limited. This was because with a normal L1/L2 cache combination, the processor read from the caches 99% of the time. A combined miss (both L1 and L2 missing) only happened about 1% of the time while reading/writing memory. Thus with SDRAM, the system would be up to 27% faster, but only about 1% of the time. Therefore, the cache performance was actually far more important than main memory performance. See the section "How Cache Works" in Chapter 3, "Microprocessor Types and Specifications," for more information.

As with the 430FX, the VX has the limitation of being capable of caching only 64MB of main memory. This means that installing more than 64MB of memory actually slows down the system dramatically because none of the memory past that point can be cached. Because Windows loads from the top of memory down, installing any amount of memory greater than 64MB in a system using this chipset dramatically decreases performance.

The 430VX chipset was rapidly made obsolete in the market by the 430TX chipset that followed.

Intel 430TX

The 430TX was Intel's final Pentium chipset. It was designed not only to be used in desktop systems, but to replace the 430MX mobile Pentium chipset for laptop and notebook systems.

The 430TX has some refinements over the 430VX, but, unfortunately, it still lacks support for parity or ECC memory and retains the 64MB cacheable RAM limitation of the older FX and VX chipsets. The 430TX was not designed to replace the more powerful 430HX chipset, which still remained the chipset of choice for Pentium class mission-critical systems.

The TX chipset features include the following:

- 66MHz SDRAM support
- Cacheable memory still limited to 64MB

- Support for Ultra-ATA, or Ultra-DMA 33 (UDMA) IDE transfers
- Lower power consumption for mobile use
- No parity or ECC memory support
- Single processor only

▶▶ See "ATA/ATAPI-4 (AT Attachment with Packet Interface Extension-4)," p. 483.

Third-Party (Non-Intel) P5 Pentium Class Chipsets

The development of non-Intel Pentium-class chipsets was spurred by AMD's development of its own equivalents to the Pentium processor—the K5 and K6 processor families. Although the K5 was not a successful processor, the K6 family, on the other hand, has been very successful in the low-cost (under-$1,000) market and as an upgrade for Pentium systems. AMD's own chipsets aren't used as often as other third-party chipsets, but AMD's capability to support its own processors with timely chipset deliveries has helped make the K6 and its successors—the Athlon and Duron—into credible rivals for Intel's Pentium MMX and Pentium II/III/Celeron families and has spurred other vendors, such as VIA, Acer Laboratories, and SiS, to support AMD's processors.

AMD 640

The AMD-640 chipset was designed by AMD for its K5 and K6 series processors. The AMD-640 chipset consists of the AMD-640 system controller in a 328-pin BGA package and the AMD-645 peripheral bus controller in a 208-pin PQFP package. The system controller includes a 64-bit Socket 7 interface, integrated writeback cache controller, system memory controller, and PCI bus controller.

Key features of the 640 chipset are

- Supports all 64-bit AMD-K5 processors and AMD-K6 processors
- Operates at processor bus speeds up to 66MHz
- Low voltage 3.3V processor interface
- Integrated L2 cache controller
- Supports pipelined burst synchronous SRAM (PBSRAM) cache
- Supports 256KB, 512KB, 1MB, and 2MB cache sizes
- Supports FPM, EDO, and SDRAM
- Maximum of 768MB of RAM; 512MB cacheable
- Supports parity and ECC memory options
- Supports PCI 2.1

Because the AMD-640 did not support bus speeds over 66MHz, it was not used with the later K6-2 and K6-III processors. These processors were supported by chipsets made by VIA Technologies and Acer Laboratories.

VIA Technologies

VIA Technologies, Inc. was founded in 1987 and has become a major designer of PC motherboard chipsets. VIA employs state-of-the-art manufacturing capability through foundry relationships with leading silicon manufacturers, such as Toshiba and Taiwan Semiconductor Manufacturing Corporation.

Apollo VP-1

The VT82C580VP Apollo VP-1 is a four-chip set released in October of 1995 and used in older Socket 5 and Socket 7 systems. The Apollo VP-1 is an equivalent alternative to the Intel 430VX chipset and features support for SDRAM, EDO, or FPM memory as well as pipeline-burst SRAM cache. The VP-1 consists of the VT82C585VP 208-pin PQFP, two VT82C587VP 100-pin PQFP chips acting as the North Bridge, and the VT82C586 208-pin PQFP South Bridge chip.

Apollo VP2

The two-chip Apollo VP2 chipset was released in May of 1996. The VP2 is a high-performance Socket 7 chipset including several features over the previous VP-1 chipset. The VP2 adds support for ECC memory over the VPX. The VP2 has also been licensed by AMD as its AMD 640 chipset. Motherboards using the Apollo VP2 can support P5 class processors, including the Intel Pentium and Pentium MMX, AMD K5 and K6, and Cyrix/IBM 6x86 and 6x86MX (MII) processors.

The VP2 chipset consists of the VT82C595 328 pin BGA package North Bridge chip, which supports up to 2MB of L2 cache and up to 512MB DRAM. Additional performance-related features include a fast DRAM controller with support for SDRAM, EDO, BEDO, and FPM DRAM types in mixed combinations with 32/64-bit data bus widths and row and column addressing; a deeper buffer with enhanced performance; and an intelligent PCI bus controller with Concurrent PCI master/CPU/IDE (PCI 2.1) operations. For data integrity and server use, the VP2/97 incorporates support for ECC or parity memory.

The Apollo VP2 features the VIA VT82C586B PCI-IDE South Bridge controller chip, which complies with the Microsoft PC97 industry specification by supporting ACPI/OnNow, Ultra DMA/33, and USB technologies.

Apollo VPX

The VT82C580VPX Apollo VPX is a four-chip set for Socket 7 motherboards released in December of 1996. The Apollo VPX is functionally equivalent to the Intel 430TX chipset but also has specific performance enhancements relative to the 430TX. The VPX was designed as a replacement for the VP-1 chipset and is an upgrade of that set designed to add support for the newer AMD and Cyrix P5 processors.

The Apollo VPX consists of the VT82C585VPX North Bridge and VT82C586B South Bridge chips. There are also two 208-pin PQFP frame buffers that go with the North Bridge memory interface. The Apollo VPX/97 features the VIA VT82C586B PCI-IDE South Bridge controller chip that complies with the Microsoft PC97 industry standard by supporting ACPI/OnNow, Ultra-DMA/33, and USB technologies. VIA also offers a non-PC97 version of the Apollo VPX that includes the older VT82C586A South Bridge and which was used in more entry-level PC designs.

Motherboards using the Apollo VPX can support P5 class processors, including the Intel Pentium and Pentium MMX, AMD K5 and K6, and Cyrix/IBM 6x86 and 6x86MX (MII) processors. To enable proper implementation of the Cyrix/IBM 6x86 200+ processor, the chipset features an asynchronous CPU bus that operates at either 66MHz or 75MHz speed. The Apollo VPX is an upgrade over the Apollo VP-1 with the additional feature of Concurrent PCI master/CPU/IDE operations (PCI 2.1). The VPX also supports up to 2MB of L2 cache and up to 512MB DRAM.

Apollo VP3

The Apollo VP3 is one of the first P5 class chipsets to implement the Intel AGP specification. Intel offers that interface with its Pentium II (P6) class chipsets. This enables a higher-performance Socket 7 motherboard to be built that can accept the faster AGP video cards. The Socket 7 interface allows P5 class processors, such as the Intel Pentium and Pentium MMX, AMD K5 and K6, and Cyrix/IBM 6x86 and 6x86MX (MII), to be used.

The Apollo VP3 chipset consists of the VT82C597 North Bridge system controller (472-pin BGA) and the VT82C586B South Bridge (208-pin PQFP). The VT82C597 North Bridge provides superior performance between the CPU; optional synchronous cache; DRAM; AGP bus; and the PCI bus with pipelined, burst, and concurrent operation. The VT82C597 complies with the Accelerated Graphics Port Specification 1.0 and features a 66MHz master system bus.

Apollo MVP3

The Apollo MVP3 adds to the VP3 chip by supporting the Super-7 100MHz Socket-7 specification. This allows the higher-speed P5 processors, such as the AMD K6-2, K6-III, and Cyrix/IBM MII processors, to be supported. The Apollo MVP3 chipset is a two-chip chipset that consists of the VT82C598AT North Bridge system controller and the VT82C586B South Bridge. The VT82C598AT chip is a 476-pin BGA package, and the VT82C586B chip is a 208-pin PQFP package.

The VT82C598AT North Bridge chip includes the CPU-to-PCI bridge, L2 cache and buffer controller, DRAM controller, AGP interface, and PCI IDE controller. The VT82C598AT North Bridge provides superior performance between the CPU; optional synchronous cache; DRAM; AGP bus; and the PCI bus with pipelined, burst, and concurrent operation. The DRAM controller supports standard FPM, EDO, and SDRAM, although most boards most likely are configured to use SDRAM only. The VT82C598AT complies with the Accelerated Graphics Port Specification 1.0 and features support for 66/75/83/100MHz CPU bus frequencies and the 66MHz AGP bus frequency.

The VT82C586B South Bridge includes the PCI-to-ISA bridge, ACPI support, SMBus, the USB host/hub interface, the Ultra-33 IDE Master controller, the PS/2 Keyboard/Mouse controller, and the I/O controller. The chip also contains the keyboard and PS/2 mouse controller.

This chipset is closest to the Intel 430TX in that it supports Socket 7 chips (Pentium and P5-compatible processors) and SDRAM DIMM memory and is physically a two-chip set. It differs mainly in that it allows operation at speeds up to 100MHz and supports AGP. The South Bridge is compatible with the newer Intel PIIX4e in that it includes UDMA IDE, USB, CMOS RAM, and ACPI 1.0 power management.

One big benefit over the Intel 430TX is that support for ECC memory or parity checking can be selected on a bank-by-bank basis, which allows mixing of parity and ECC modules. The 430TX from Intel doesn't support any ECC or parity functions at all. Memory timing for FPM is X-3-3-3, whereas EDO is X-2-2-2, and SDRAM is X-1-1-1, which is similar to the Intel 430TX.

Another benefit over the 430TX is in memory cacheability. The 430TX allowed caching up to only 64MB of main memory, a significant limitation. The maximum cacheable range is determined by a combination of cache memory size and the number of cache tag bits used. The most common L2 cache sizes are 512KB or 1MB of L2 cache on the motherboard, allowing either 128MB or 256MB of main memory to be cached. The maximum configuration of 2MB of L2 cache allows up to 512MB of main memory to be cacheable.

The MVP3 seems to be the chipset of choice in the higher-end Socket 7 motherboards from DFI, FIC, Tyan, Acer, and others.

Apollo MVP4

The Apollo MVP4 is a high-end Super Socket 7 chipset designed to support the highest-speed AMD-K6-2, K6-III, and VIA Cyrix MII processors. The VIA Apollo MVP4 chipset consists basically of the MVP3 chipset combined with a built-in AGP2x Trident Blade3D graphics engine. This is designed for low-cost systems with integrated video.

Features of the MVP4 include

- Integrated AGP2x bus
- Integrated Trident Blade3D AGP graphics engine
- 66/75/83/95/100MHz processor bus speed settings
- Support for AMD-K6, AMD-K6-2, AMD-K6-III, and VIA Cyrix MII processors running at speeds of up to 533MHz
- PC-100 memory bus
- Support for up to 768MB PC100 SDRAM
- Integrated AC97 audio, Super I/O, USB, advanced power management, and hardware-monitoring capabilities
- Support for ATA-66
- Support for four USB ports

The VIA Apollo MVP4 chipset is a two-chip set consisting of the VT8501 North Bridge Controller paired with the VT82C686A South Bridge Controller for full-featured systems or the VT82C596B Mobile South Bridge Controller for mobile systems.

Acer Laboratories, Inc.

Acer Laboratories, Inc. (ALi) originally was founded in 1987 as an independent research and development center for the Acer Group. In 1993, ALi separated financially and legally from Acer Inc., and became a member company of the Acer Group. ALi has rapidly claimed a prominent position among PC chipset manufacturers.

Aladdin IV (Aladdin 4)

The Aladdin IV from Acer Labs is a two-chip set for P5 class processors consisting of the M1531 North Bridge and either an M1533 or M1543 South Bridge chip. The Aladdin IV supports all Intel, AMD, Cyrix/IBM, and other P5-class CPUs including the Intel Pentium and Pentium MMX, AMD K5 and K6, and Cyrix/IBM 6x86 and 6x86MX (MII) processors. The Aladdin IV is equivalent to the Intel 430TX chipset, with the addition of error-correcting memory support and higher-speed 75MHz and 83.3MHz operation. Also, when using the M1543 South Bridge, an additional Super I/O chip is not necessary because those functions are included in the M1543 South Bridge.

The M1531 North Bridge is a 328-pin BGA chip that supports CPU bus speeds of 83.3MHz, 75MHz, 66MHz, 60MHz, and 50MHz. The M1531 also supports pipelined-burst SRAM cache in sizes of up to 1MB, allowing either 64MB (with 8-bit tag SRAM) or up to 512MB (with 11-bit tag SRAM) of cacheable main memory. FPM, EDO, or SDRAM main memory modules are supported for a total capacity of 1GB in up to four total banks. Memory timing is 6-3-3-3 for back-to-back FPM reads, 5-2-2-2 for back-to-back EDO reads, and 6-1-1-1 for back-to-back SDRAM reads. For reliability and integrity in mission-critical or server applications, ECC or parity is supported. PCI spec. 2.1 is also supported, allowing concurrent PCI operations.

The M1533 South Bridge integrates ACPI support, two-channel Ultra-DMA 33 IDE master controller, two-port USB controller, and a standard keyboard/mouse controller. A more full-function M1543 South Bridge is also available that has everything in the M1533 South Bridge plus all the functions of a normally separate Super I/O controller. The M1543 integrates ACPI support, two-channel Ultra-DMA 33 IDE controller, two-port USB controller, and a standard keyboard/mouse controller. Also included is an integrated Super I/O including a 2.88MB floppy disk controller, two high-performance serial ports, and a multimode parallel port. The serial ports incorporate 16550-compatible universal asynchronous receiver transmitters (UARTs) with 16-byte first in first out (FIFO) buffers and SIR (serial infrared) capability. The multimode parallel port includes support for Standard Parallel Port (SPP) mode, PS/2 Bidirectional mode, Enhanced Parallel Port (EPP) mode, and the Microsoft and Hewlett-Packard Extended Capabilities Port (ECP) mode.

Aladdin V (Aladdin 5)

The Acer Labs Aladdin V Chipset is a two-chip set that consists of the M1541 North Bridge chip and the M1533 (see "Aladdin IV" for details) or M1543C/M1453 South Bridge/Super I/O controller combo chip. The M1541 North Bridge is a 456-pin BGA package chip, whereas the M1543C South Bridge is a 330-pin- BGA package chip (the now-discontinued M1543 South Bridge was a 328-pin BGA package chip). The M1541 chipset is similar to the previous M1532 chipset with the addition of higher-speed (up to 100MHz) operation and AGP support.

The M1541 North Bridge includes the CPU-to-PCI bridge, L2 cache and buffer controller, DRAM controller, AGP interface, and PCI controller. The M1541 supports the Super-7 high-speed 100MHz Socket 7 processor interface used by some of the newer AMD and Cyrix/IBM P5 processors. It also runs the processor bus at 83.3MHz, 75MHz, 66MHz, 60MHz, and 50MHz for backward compatibility. When running the CPU bus at 75MHz, the PCI bus runs only at 30MHz; however, when the CPU bus is running at 83.3MHz or 100MHz, the PCI bus runs at full 33MHz PCI standard speed.

The M1541 also integrates enough cache tag RAM (16KB×10) internally to support 512KB of L2 cache, simplifying the L2 cache design and further reducing the number of chips on the motherboard. Cacheable memory is up to 512MB of RAM when using 512KB L2 cache and 1GB of RAM when using 1MB of L2 cache. FPM, EDO, or SDRAM memory is supported, in up to four banks and up to 1GB total RAM. ECC/Parity is also supported for mission-critical or fileserver applications to improve reliability. Memory timing is 6-3-3-3-3-3-3-3 for back-to-back FPM reads, 5-2-2-2-2-2-2-2 for back-to-back EDO reads, and 6-1-1-1-2-1-1-1 for back-to-back SDRAM reads. For more information on memory timing, see Chapter 6, "Memory."

Finally, AGP Interface specification V1.0 is supported in 1x and 2x modes.

The M1543 South Bridge and Super I/O combo chip includes ACPI support, the USB host/hub interface, the dual-channel Ultra-DMA/33 IDE host interface, the keyboard and mouse controller, and the Super I/O controller. The built-in Super I/O consists of an integrated floppy disk controller, two serial ports with infrared support, and a multimode parallel port. This South Bridge has been replaced by the M1543C, which has similar features but supports Ultra-DMA/66 IDE hard disk instead of the UDMA/33 supported by the M1543; it also adds support for IrDA infrared serial ports and ACPI power management. The M1543C South Bridge can also be used with Pentium II-family processors.

The Aladdin V can also be used with the M1533 South Bridge, which must be used with a separate Super I/O chip. See the description of the Aladdin IV for details about the M1533 South Bridge.

Aladdin 7

The Acer Labs Aladdin 7 chipset consists of the M1561 North Bridge and either the M1535D or M1543C South Bridge chip. The M1561 North Bridge is a 492-pin thermally enhanced BGA (T 2 BGA) package chip, whereas the M1535D South Bridge is a 352-pin BGA package chip.

Aladdin 7's M1561 North Bridge integrates 3D graphics, 2D acceleration, VGA video, the SDRAM memory controller, and the PCI bus interface into its North Bridge chip. It supports unified memory architecture (UMA), which enables low-cost systems to share system memory with the video subsystem. It supports the CPU-to-PCI bridge, L2 cache and buffer controller, DRAM controller, and PCI controller (supporting PCI version 2.2). The M1561 supports Super 7 processors and up to 1GB of RAM at 66MHz, 100MHz, and 133MHZ FSB speeds. Its 128-bit memory pipeline is designed to run faster than other integrated-video chipsets, with a memory bandwidth up to 2.1GBps when used with two matched DIMM modules.

M1561's onboard 3D video is provided by ArtX (which is also providing graphics logic for Nintendo's new system) and features hardware-accelerated transform and lighting (T&L), standard 3D features, a setup engine, parallel rendering, and high-speed 8x AGP-equivalent performance. Its display controller supports 1,600×1,200 onscreen resolution, motion-compensated 30fps DVD playback, and 32-bit full-color support.

Unfortunately, this chipset doesn't support Level 2 cache because it was designed for the discontinued AMD K6-III CPU (which featured 256KB of L2 cache onboard). Thus, it provides very poor performance with AMD's K6-2 processor, which lacks its own L2 cache. However, it is a good match for the K6-2 Plus, which has 128KB of Level 2 cache onboard.

Silicon Integrated Systems

Silicon Integrated Systems (SiS) was formerly known as Symphony Labs and is one of the three largest non-Intel PC motherboard chipset manufacturers.

SiS540

The SiS540 chipset is a single chipset that combines North/South Bridge functions as well as video and networking all into a single chip. The SiS540 is a super Socket 7 chipset supporting AMD K6-2/K6-III and VIA Cyrix processors.

The integrated video is based on a 128-bit graphic display interface with AGP 2x performance. In addition to providing a standard analog interface for CRT monitors, the SiS540 provides the Digital Flat Panel Port (DFP) for a digital flat panel monitor. An optional SiS301 Video Bridge supports NTSC/PAL TV output.

The SiS540 also includes integrated 10/100Mb Fast Ethernet as well as an AC97-compliant interface that comprises digital audio engine with 3D-hardware accelerator, on-chip sample rate converter, and professional wavetable along with separate modem DMA controller. SiS540 also incorporates the Low Pin Count (LPC) interface for attaching newer Super I/O chips and a dual USB host controller with four USB ports.

Features of the SiS540 include

- Supports Intel/AMD/Cyrix/IDT Pentium CPU processor bus at 66/83/90/95/100MHz
- Integrated 2MB Level 2 cache controller
- Supports PC133 SDRAM
- Meets PC99 requirements
- Is PCI 2.2 compliant
- Supports Ultra DMA66/33
- Integrated AGP 2x 2D/3D Video/Graphics Accelerator
- Supports digital flat panel
- Built-in secondary CRT controller for independent secondary CRT, LCD, or TV digital output
- Low Pin Count Interface
- Advanced PCI H/W Audio and S/W Modem
- Meets ACPI 1.0 requirements
- PCI Bus Power Management Interface Spec. 1.0
- Integrated keyboard/mouse controller
- Dual USB controller with four USB ports
- Integrated 10/100Mb/sec Ethernet controller

SiS 530/5595

The SiS530/5595 chipset is a two-chip chipset that includes the SiS530 North Bridge and the 5595 South Bridge and integrates 3D video. The SiS530/5595 is a Super Socket 7 chipset supporting AMD K6-2/K6-III and VIA Cyrix processors.

The integrated video is based on a 64-bit graphic display interface with AGP performance. In addition to providing a standard analog interface for CRT monitors, the SiS530/5595 provides the DFP for a digital flat panel monitor. It also supports UMA memory up to 8MB.

The 5595 South Bridge also includes an integrated Super I/O interface including USB host controller with two USB ports.

Features of the SiS540 include

- Supports Intel/AMD/Cyrix/IDT Pentium CPU processor bus at 66/83/90/95/100MHz
- Integrated 2MB Level 2 cache controller
- Caches up to 256MB SDRAM
- Supports PC100 SDRAM
- Meets PC99 requirements
- Is PCI 2.2 compliant
- Supports Ultra DMA66/33
- Integrated AGP 2D/3D Video/Graphics Accelerator
- Supports digital flat panel
- Built-in secondary CRT controller for independent secondary CRT, LCD, or TV digital output
- Meets ACPI 1.0 requirements
- PCI Bus Power Management Interface Spec. 1.0
- Integrated keyboard/mouse controller
- USB controller with two USB ports

SiS598

The Sis5598 chip is a 553-pin BGA package single-chip set incorporating both North and South Bridge functions. The 5598 consists of both North and South Bridge functions, including PCI-to-ISA bridge function, PCI IDE function, USB host/hub function, integrated RTC, integrated keyboard controller, and onboard PCI VGA. These chips support CPU bus speeds of 50MHz, 55MHz, 60MHz, 66MHz, and 75MHz.

A maximum of 512KB of L2 cache is supported, with a maximum cacheable range of 128MB of main memory. ECC or parity functions are not supported. Main memory timing is 5-3-3-3 for FPM, EDO timing is 5-2-2-2, and SDRAM timing is 6-1-1-1.

The 5598 chip also includes Advanced Configuration and Power Interface (ACPI) power management, a dual-channel Ultra-DMA/33 IDE interface, a USB controller, and even the CMOS RAM and Real Time Clock (RTC). PCI v2.1 is supported that allows concurrent PCI operation; however, AGP is not supported in this chipset.

5581, 5582, and 5571

The SiS5581 and 5582 chips are both 553-pin BGA package single-chip sets incorporating both North and South Bridge functions. The SiS5582 is targeted for AT/ATX form factor motherboards, whereas the SiS5581 is intended to be used on LPX/NLX form factor boards. In all other ways, the two North

Bridge chips are identical. The SiS 5581/5582 is a single-chip set designed to be a high-performance, low-cost alternative that is functionally equivalent to Intel's 430TX chipset. By having everything in a single chip, a low-cost motherboard can be produced.

The 5581/5582 consists of both North and South Bridge functions, including PCI-to-ISA bridge function, PCI IDE function, USB host/hub function, integrated RTC, and the integrated keyboard controller. These chips support CPU bus speeds of 50MHz, 55MHz, 60MHz, 66MHz, and 75MHz.

A maximum of 512KB of L2 cache is supported, with a maximum cacheable range of 128MB of main memory. The maximum cacheable range is determined by a combination of cache memory size and the number of tag bits used. The most common cache size that allows caching of up to 128MB of RAM is 512KB, although up to 384MB of RAM can technically be installed in up to three total banks. Because this is designed for low-cost systems, ECC or parity functions are not supported. Main memory timing is x-3-3-3 for FPM, EDO timing is x-2-2-2, and SDRAM timing is x-1-1-1.

The 5581/5582 chipset also includes ACPI power management, a dual-channel Ultra-DMA/33 IDE interface, a USB controller, and even the CMOS RAM and RTC. PCI v2.1 is supported that allows concurrent PCI operation; however, AGP is not supported in this chipset.

The 5571 is an older version of this single-chip set, lacks support for bus speeds above 66MHz, supports only the older APM power management standard, and supports only PIO modes for hard disk access. The 5571 uses a 480-pin BGA package.

5591 and 5592

The SiS 5591/5592 is a two-chip set consisting of either a 5591 or 5592 North Bridge chip along with a SiS5595 South Bridge. The 5591/5592 North Bridge chips are both 3.3v 553-pin BGA package chips, whereas the 5595 South Bridge chip is a 5v 208-pin PQFP package chip. The SiS5591 North Bridge is targeted for ATX form factor motherboards, and the SiS5592 version is intended to be used on the NLX form factor. In all other ways, the two North Bridge chips are identical.

The 5591/5592 North Bridge chips include the host-to-PCI bridge, L2 cache controller, DRAM controller, AGP interface, and PCI IDE controller. The SiS5595 South Bridge includes the PCI-to-ISA bridge; ACPI/APM power management unit; USB host/hub interface; and ISA bus interface, which contains the ISA bus controller, DMA controllers, interrupt controllers, and timers. It also integrates the keyboard controller and RTC.

The 5591/5592 North Bridge chips support CPU bus speeds of up to 75MHz. They also support up to 1MB of L2 cache, allowing up to 256MB of main memory to be cacheable. The maximum cacheable main memory amount is determined by a combination of cache memory size and the number of tag bits used. Most common cache sizes are 512KB and 1MB. The 512KB cache with 7 tag bits allow only 64M of memory to be cached, whereas 8 tag bits allow caching of up to 128MB. With 1MB of cache onboard, the cacheable range is doubled to a maximum of 256MB.

A maximum of 256MB of total RAM is allowed in up to three banks. Both ECC and parity are supported for mission-critical or fileserver applications. Main memory timing for FPM memory is x-3-3-3, EDO timing is x-2-2-2, and SDRAM is x-1-1-1.

PCI specification 2.1 is supported at up to 33MHz, and AGP specification 1.0 is supported in both 1x and 2x modes. The separate 5595 South Bridge includes a dual-channel Ultra-DMA/33 interface and support for USB.

Sixth-Generation (P6 Pentium Pro/II/III Class) and Seventh-Generation (Pentium 4) Chipsets

Just as Intel clearly dominated the Pentium chipset world, it is also the leading vendor for chipsets supporting its P6, P7, and later processor families. As discussed earlier, the biggest reason for this is that, since the Pentium first came out in 1993, Intel has been introducing new chipsets (and even complete ready-to-go motherboards) simultaneously with its new processors. This makes it hard for anybody else to catch up. Another problem for other chipset manufacturers is that Intel had been reluctant until recently to license the Slot 1, Socket 370, and now Socket 423 interfaces used by the newer processors, although the Socket 7 interface used by the original Pentium has been freely available for license for some time. Still, some licenses have been granted, and other chipmakers, such as VIA Technologies, ,ALi, and SiS, have developed a wide range of Slot 1 and Socket 370 chipsets. The first license agreements for Socket 423, used by the Pentium 4, were inked early in 2001, paving the way for non-Intel chipsets for its newest processor in the future.

Note that because the Pentium Pro, Celeron, and Pentium II/III are essentially the same processor with different cache designs and minor internal revisions, the same chipset can be used for Socket 8 (Pentium Pro), Socket 370 (Celeron/Pentium III), and Slot 1 (Celeron/Pentium II/III) designs. Of course, the newer P6-class chipsets are optimized for the Socket 370 architecture and nobody is making any new designs for Socket 8 or Slot 1.

Table 4.8 shows the chipsets used on Pentium Pro motherboards.

Table 4.8 Pentium Pro Motherboard Chipsets (North Bridge)

Chipset	450KX	450GX	440FX
Codename	Orion	Orion Server	Natoma
Workstation date introduced	Nov. 1995	Nov. 1995	May 1996
Bus speed	66MHz	66MHz	66MHz
SMP (dual CPUs)	Yes	Yes (four CPUs)	Yes
Memory types	FPM	FPM	FPM/EDO/BEDO
Parity/ECC	Both	Both	Both
Maximum memory	8GB	1GB	1GB
L2 cache type	In CPU	In CPU	In CPU
Maximum cacheable	1GB	1GB	1GB
PCI support	2.0	2.0	2.1
AGP support	No	No	No
AGP speed	n/a	n/a	n/a
South Bridge	Various	Various	PIIX3

SMP = Symmetric multiprocessing (dual processors)
FPM = Fast page mode
EDO = Extended data out
BEDO = Burst EDO
SDRAM = Synchronous dynamic RAM
Pburst = Pipeline burst (synchronous)
PCI = Peripheral component interconnect
AGP = Accelerated graphics port
SIO = System I/O
PIIX = PCI ISA IDE Xcelerator

Note

PCI 2.1 supports concurrent PCI operations.

For the Celeron and Pentium II/III motherboards, Intel offers the chipsets in Table 4.9. 4xx series chipsets incorporate a North/South Bridge architecture, whereas 8xx series chipsets support the newer and faster hub architecture. P6/P7 (Pentium III/Celeron, Pentium 4, and Xeon) processor chipsets using hub architecture are shown in Table 4.10.

South Bridge (Hub)	82801AA/ AB (ICH/ ICH0)	82801AA (ICH)	82801AA (ICH)	82801BA (ICH2)	82801BA (ICH2)

1. Note the 440ZX is available in a cheaper 440ZX-66 version, which runs only at 66MHz.

2. Note the 810 chipsets have integral AGP 2x 3D video, which is NOT upgradable via an external AGP adapter.

3. Note the 815/815E chipsets have integral AGP 2x 3D video, which IS upgradable via an APG 4x slot.

4. Note the only difference between the 815 and 815E is in which I/O controller hub (South Bridge) is used.

SMP = Symmetric multiprocessing (dual processors).

Note

Pentium Pro, Celeron, and Pentium II/III CPUs have their secondary caches integrated into the CPU package. Therefore, cache characteristics for these machines are not dependent on the chipset but are quite dependent on the processor instead.

Most Intel chipsets are designed as a two-part system, using a North Bridge and a South Bridge component. Often the same South Bridge component can be used with several different North Bridge chipsets. Table 4.11 shows a list of all the current Intel South Bridge components and their capabilities.

Table 4.11 Intel South Bridge—I/O Controller Hub Chips

82801AA (ICH)	82801BA (ICH2)	82801AA (ICH)	82801BA (ICH2)	82801BA (ICH2)

FPM = Fast page mode.
EDO = Extended data out.
BEDO = Burst EDO.
SDRAM = Synchronous dynamic RAM.
Pburst = Pipeline burst (synchronous).
PCI = Peripheral component interconnect.
AGP = Accelerated graphics port.
SIO = System I/O.
PIIX = PCI ISA IDE Xcelerator.
ICH = I/O controller hub.

The following sections examine the chipsets for P6 processors up through the Celeron and Pentium III.

Intel 450KX/GX (Orion Workstation/Server)

The first chipsets to support the Pentium Pro were the 450KX and GX, both codenamed Orion. The 450KX was designed for networked or standalone workstations; the more powerful 450GX was designed for fileservers. The GX server chipset was particularly suited to the server role because it supports up to four Pentium Pro processors for symmetric multiprocessing (SMP) servers, up to 8GB of four-way interleaved memory with ECC or parity, and two bridged PCI buses. The 450KX is the workstation or standalone user version of Orion and as such it supports fewer processors (one or two) and less memory (1GB) than the GX. The 450GX and 450KX both have full support for ECC memory—a requirement for server and workstation use.

The 450GX and 450KX North Bridge comprises four individual chip components—an 82454KX/GX PCI bridge, an 82452KX/GX data path (DP), an 82453KX/GX data controller (DC), and an 82451KX/GX memory interface controller (MIC). Options for QFP or BGA packaging were available on the PCI Bridge and the DP. BGA uses less space on a board.

The 450's high reliability is obtained through ECC from the Pentium Pro processor data bus to memory. Reliability is also enhanced by parity protection on the processor bus, control bus, and all PCI signals. In addition, single-bit error correction is provided, thereby avoiding server downtime because of spurious memory errors caused by cosmic rays.

Until the introduction of the following 440FX chipset, these were used almost exclusively in fileservers. After the debut of the 440FX, the expensive Orion chips all but disappeared due to their complexity and high cost.

Intel 440FX (Natoma)

The first popular mainstream P6 (Pentium Pro or Pentium II) motherboard chipset was the 440FX, which was codenamed Natoma. The 440FX was designed by Intel to be a lower-cost and somewhat higher-performance replacement for the 450KX workstation chipset. It offered better memory performance through support of EDO memory, which the prior 450KX lacked.

The 440FX uses half the number of components than the previous Intel chipset. It offers additional features, such as support for the PCI 2.1 (concurrent PCI) standard, support for USB, and reliability through ECC.

The concurrent PCI processing architecture maximizes system performance with simultaneous activity on the CPU, PCI, and ISA buses. Concurrent PCI provides increased bandwidth to better support 2D/3D graphics, video and audio, and processing for host-based applications. ECC memory support delivers improved reliability to business system users.

The main features of this chipset include

- Support for up to 1GB of EDO memory
- Full 1GB cacheability (based on the processor because the L2 cache and tag are in the CPU)
- Support for USB
- Support for Bus Master IDE
- Support for full parity/ECC

The 440FX consists of a two-chip North Bridge. The main component is the 82441FX PCI Bridge and Memory controller, along with the 82442FX Data Bus accelerator for the PCI bus. This chipset uses the PIIX3 82371SB South Bridge chip that supports high-speed Bus Master DMA IDE interfaces and USB, and it acts as the bridge between the PCI and ISA buses.

Note that this was the first P6 chipset to support EDO memory, but it lacked support for the faster SDRAM. Also, the PIIX3 used with this chipset does not support the faster Ultra DMA IDE hard drives.

The 440FX was the chipset used on the first Pentium II motherboards, which have the same basic architecture as the Pentium Pro. The Pentium II was released several months before the chipset that was supposedly designed for it was ready, so early PII motherboards used the older 440FX chipset. This chipset was never designed with the Pentium II in mind, whereas the newer 440LX was optimized specifically to take advantage of the Pentium II architecture. For that reason, I normally recommended that people stay away from the original 440FX-based PII motherboards and wait for Pentium II systems that used the forthcoming 440LX chipset. When the new chipset was introduced, the 440FX was quickly superseded by the improved 440LX design.

Intel 440LX

The 440LX quickly took over in the marketplace after it debuted in August of 1997. This was the first chipset to really take full advantage of the Pentium II processor. Compared to the 440FX, the 440LX chipset offers several improvements:

- Support for the new AGP video card bus
- Support for 66MHz SDRAM memory
- Support for the Ultra DMA IDE interface
- Support for USB

The 440LX rapidly became the most popular chip for all new Pentium II systems from the end of 1997 through the beginning of 1998.

Intel 440EX

The 440EX was designed to be a low-cost, lower-performance alternative to the 440LX chipset. It was introduced in April 1998, along with the Intel Celeron processor. The 440EX lacks several features in the more powerful 440LX, including dual processor and ECC or parity memory support. This chipset is basically designed for low-end 66MHz bus-based systems that use the Celeron processor. Note that boards with the 440EX also fully support a Pentium II but lack some of the features of the more powerful 440LX or 440BX chipsets.

The main things to note about the 440EX are listed here:

- Designed with a feature set tuned for the low-end PC market
- Primarily for the Intel Celeron processor
- Supports AGP
- Does not support ECC or parity memory
- Single processor support only

The 440EX consists of an 82443EX PCI AGP Controller (PAC) North Bridge component and the new 82371EB (PIIX4E) South Bridge chip.

Note

The original 266MHz and 300MHz Celeron processors used with the 440EX chipset provided very low performance because these processors lacked any onboard Level 2 cache memory. Starting with the 300MHz Celeron 300A, Celeron added 128KB of Level 2 cache to its SEP packaging; all Socket 370 Celerons also include Level 2 cache. You should consider upgrading to a faster Celeron CPU with Level 2 cache if your 440EX-based system uses one of the original Celeron processors.

Intel 440BX

The Intel 440BX chipset was introduced in April of 1998 and was the first chipset to run the processor host bus (often called the front-side bus, or FSB) at 100MHz. The 440BX was designed specifically to support the faster Pentium II/III processors at 350MHz and higher. A mobile version of this chipset is the first Pentium II/III chipset for notebook or laptop systems.

The main change from the previous 440LX to the BX is that the 440BX chipset improves performance by increasing the bandwidth of the system bus from 66MHz to 100MHz. Because the chipset can run at either 66MHz or 100MHz, it allows one basic motherboard design to support all Pentium II/III processor speeds based on either the 66MHz or 100MHz processor bus.

Here are the Intel 440BX highlights:

- Support for 100MHz SDRAM (PC100); the now-common PC133 RAM can also be installed, but it will still run at just 100MHz
- Support for both 100MHz and 66MHz system and memory bus designs
- Support for up to 1GB of memory in up to four banks (four DIMMs)
- Support for ECC memory
- Support for ACPI
- The first chipset to support the Mobile Intel Pentium II processor

▶▶ See "Mobile Pentium II and III," p. 1175.

The Intel 440BX consists of a single North Bridge chip called the 82443BX Host Bridge/Controller, which is paired with a new 82371EB PCI-ISA/IDE Xcelerator (PIIX4E) South Bridge chip. The new South Bridge adds support for the ACPI specification version 1.0. Figure 4.28 shows a typical system block diagram using the 440BX.

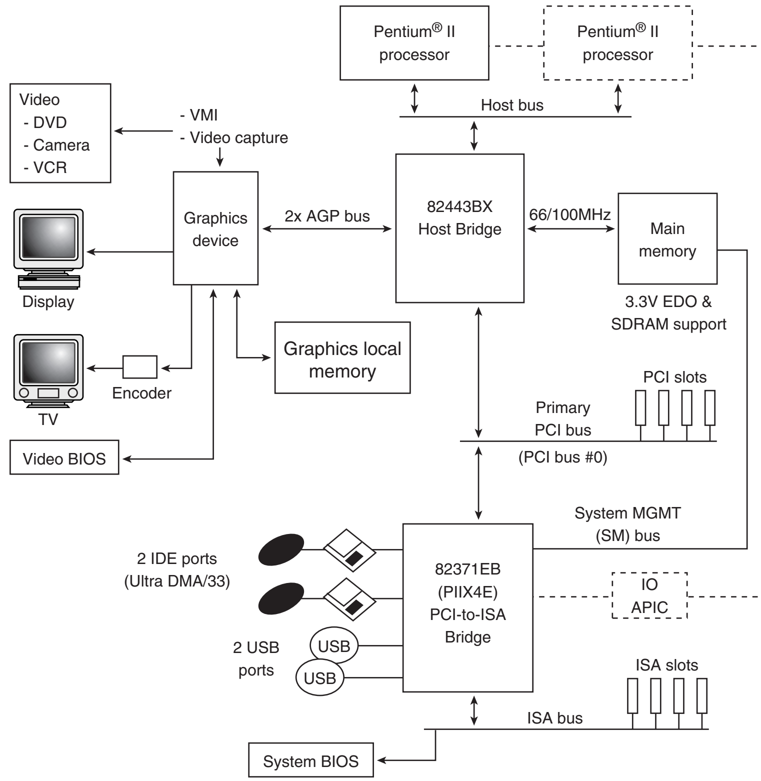

Figure 4.28 System block diagram using the Intel 440BX chipset.

The 440BX was a popular chipset during 1998 and into 1999. It offered superior performance and high reliability through the use of ECC, SDRAM, and DIMMs.

Intel 440ZX and 440ZX-66

The 440ZX was designed to be a low-cost version of the 440BX. The 440ZX brings 66MHz or 100MHz performance to entry-level Celerons (with or without Level 2 cache) and low-end Pentium II/III systems. The 440ZX is pin compatible with the more expensive 440BX, meaning existing 440BX motherboards can be easily redesigned to use this lower-cost chipset.

Note that two versions of the 440ZX are available: The standard one runs at 100MHz or 66MHz, and the 440ZX-66 runs only at the slower 66MHz.

The features of the 440ZX include the following:

- Support for Celeron and Pentium II/III processors at up to 100MHz bus speeds
- These main differences from the 440BX:
  - No parity or ECC memory support
  - Only two banks of memory (two DIMMs) supported
  - Maximum memory only 256MB

The 440ZX is not a replacement for the 440BX; instead, it was designed to be used in less expensive systems (such as those based on the micro-ATX form factor), in which the greater memory capabilities, performance, and data integrity functions (ECC memory) of the 440BX are not necessary.

Intel 440GX

The Intel 440GX AGP set is the first chipset optimized for high-volume midrange workstations and lower-cost servers. The 440GX is essentially a version of the 440BX that has been upgraded to support the Slot 2 (also called SC330) processor slot for the Pentium II/III Xeon processor. The 440GX can still be used in Slot 1 designs, as well. It also supports up to 2GB of memory, twice that of the 440BX. Other than these items, the 440GX is essentially the same as the 440BX. Because the 440GX is core compatible with the 440BX, motherboard manufacturers could quickly and easily modify their existing Slot 1 440BX board designs into Slot 1 or 2 440GX designs.

The main features of the 440GX include

- Support for Slot 1 and Slot 2
- Support for 100MHz system bus
- Support for up to 2GB of SDRAM memory

This chipset allows for lower-cost, high-performance workstations and servers using the Slot 2–based Xeon processors.

Intel 450NX

The 450NX chipset is designed for multiprocessor systems and standard high-volume servers based on the Pentium II/III Xeon processor. The Intel 450NX chipset consists of four components: the 82454NX PCI Expander Bridge (PXB), 82451NX Memory and I/O Bridge Controller (MIOC), 82452NX RAS/CAS Generator (RCG), and 82453NX Data Path Multiplexor (MUX).

The 450NX supports up to four Pentium II/III Xeon processors at 100MHz. Two dedicated PCI Expander Bridges can be connected via the Expander Bus. Each PXB provides two independent 32-bit, 33MHz PCI buses, with an option to link the two buses into a single 64-bit, 33MHz bus.

Figure 4.29 shows a typical high-end server block diagram using the 450NX chipset.

The 450NX supports one or two memory cards. Each card incorporates an RCG chip and two MUX chips, in addition to the memory DIMMs. Up to 8GB of memory is supported in total.

The primary features of the 450NX include the following:

- Slot 2 (SC330) processor bus interface at 100MHz
- Support for up to four-way processing
- Support for two dedicated PCI Expander Bridges
- Up to four 32-bit PCI buses or two 64-bit PCI buses

The 450NX chipset does not support AGP because high-end video is not an issue in network file-servers.

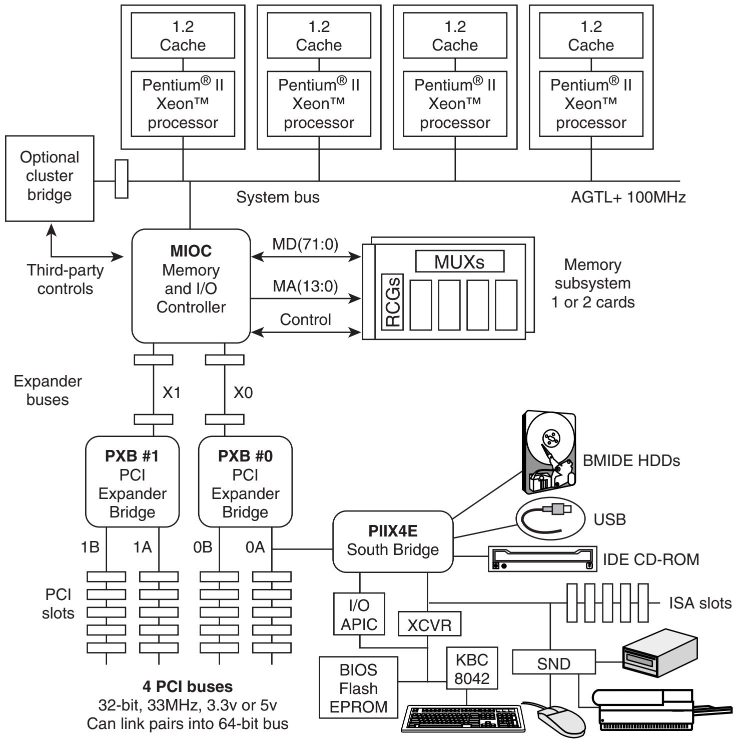

Figure 4.29 High-end server block diagram using the Intel 440NX chipset.

Intel 810, 810E, and 810E2

Introduced in April of 1999, the Intel 810 chipset (codenamed Whitney) represents a major change in chipset design from the standard North and South Bridges that have been used since the 486 days. The 810 chipset allows for improvements in system performance, all for less cost and system complexity. The 810 (which supports 66MHz and 100MHz processor buses) was later revised as the 810E with support for the 133MHz processor bus.

Note

The 810E2 uses the same 82810E GMCH as the 810E but pairs it with the 82801BA I/O Controller Hub (ICH2) used by the Intel 815E. For information about the 82801BA ICH2 chip, see the section "Intel 815, 815E, and 815EP," later in this chapter.

The major features of the 810E chipset include

- 66/100/133MHz system bus
- Integrated AGP2x Intel 3D graphics
- Efficient use of system memory for graphics performance

- Optional 4MB of dedicated display cache video memory
- Digital Video Out port compatible with DVI specification for flat panel displays
- Software MPEG-2 DVD playback with hardware motion compensation
- 266MB/sec hub interface
- Support for ATA-66
- Integrated Audio-Codec 97 (AC97) controller
- Support for low-power sleep modes
- Random number generator (RNG)
- Integrated USB controller
- LPC bus for Super I/O and Firmware Hub (ROM BIOS) connection
- Elimination of ISA bus

The 810E chipset consists of three major components (see Figure 4.30):

- *82810E Graphics Memory Controller Hub (GMCH)*. 421 BGA package (the original 810 chipset used the 82810 GMCH)
- *82801 Integrated Controller Hub (ICH)*. 241 BGA package
- *82802 Firmware Hub (FWH)*. In either 32-pin plastic leaded chip carrier (PLCC) or 40-pin thin small outline package (TSOP) packages; although a functional part of the chipset, this component is actually sold separately by Intel to motherboard developers

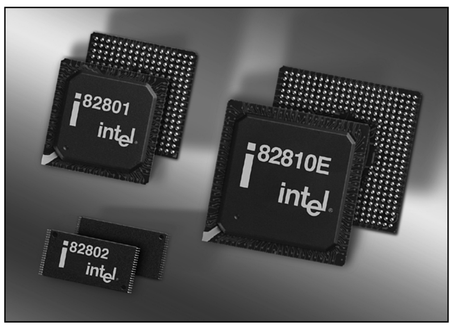

Figure 4.30 Intel 810E chipset showing the 82810E (GMCH), 82801 (ICH), and 82802 (FWH) chips. *Photograph used by permission of Intel Corporation.*

Compared to the previous North/South Bridge designs, there are some fairly significant changes in the 810 chipset. The previous system designs had the North Bridge acting as the memory controller, talking to the South Bridge chip via the PCI bus. This new design has the GMCH taking the place of the North Bridge, which talks to the ICH via a 66MHz dedicated interface called the accelerated hub architecture (AHA) bus instead of the previously used PCI bus. In particular, implementing a direct connection between the North and South Bridges in this manner was key in implementing the new UDMA-66 high-speed IDE interface for hard disks, DVD drives, and other IDE devices.

Figure 4.31 shows a system block diagram for the 810E chipset. With the 810 chipset family, ISA is finally dead.

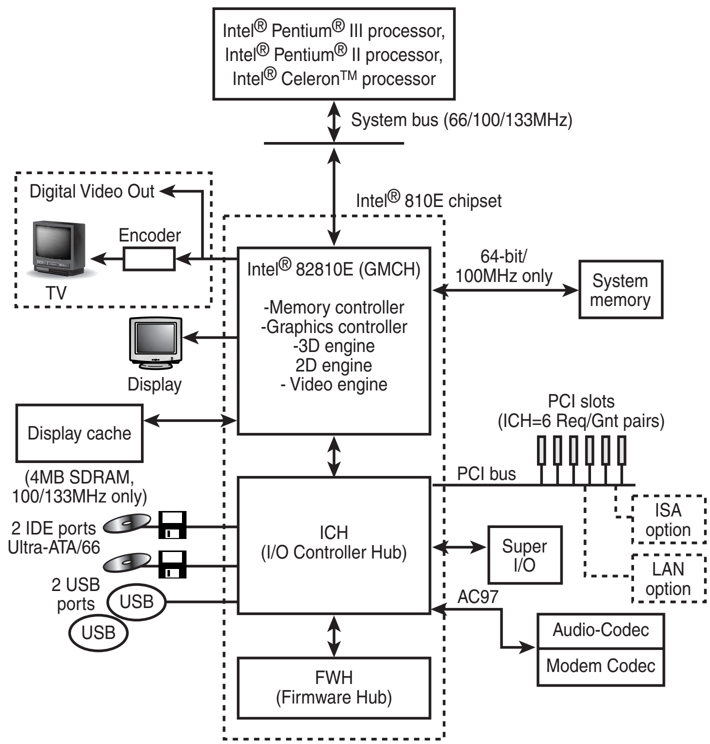

Figure 4.31 Intel 810E chipset system block diagram.

The 82810E GMCH uses an internal Direct AGP (integrated AGP) interface to create 2D and 3D effects and images. The video capability integrated into the 82810E chip features hardware motion compensation to improve software DVD video quality; it also features both analog and direct digital video out ports, which enable connections to either traditional TVs (via an external converter module) or the new direct digital flat panel displays. The GMCH chip also incorporates the System Manageability Bus, which enables networking equipment to monitor the 810 chipset platform. Using ACPI specifications, the system manageability function enables low-power sleep mode and conserves energy when the system is idle.

The 82801 I/O Controller Hub employs AHA for a direct connection from the GMCH chip. This is twice as fast (266MB/sec) as the previous North/South Bridge connections that used the PCI bus, and it uses far fewer pins for reduced electrical noise. Plus, the AHA bus is dedicated, meaning that no other devices will be on it. The AHA bus also incorporates optimized arbitration rules allowing more functions to run concurrently, enabling better video and audio performance.

The ICH also integrates dual IDE controllers, which run up to either 33MB/sec (UDMA-33 or Ultra-ATA/33) or 66MB/sec (UDMA-66 or Ultra-ATA/66). Note that two versions of the ICH chip exist. The 82801AA (ICH) incorporates the 66MB/sec-capable ATA/IDE and supports up to six PCI slots, whereas the 82801AB (ICH0) supports only 33MB/sec ATA/IDE maximum and supports up to four PCI slots.

The ICH also integrates an interface to an Audio-Codec 97 (AC97) controller, dual USB ports, and the PCI bus with up to four or six slots. The Integrated Audio-Codec 97 controller enables software audio and modem by using the processor to run sound and modem software via very simple digital-to-analog conversion circuits. By reusing existing system resources, this lowers the system cost by eliminating components.

The 82802 Firmware Hub (FWH) incorporates the system BIOS and video BIOS, eliminating a redundant nonvolatile memory component. The BIOS within the FWH is flash-type memory, so it can be field-updated at any time. In addition, the 82802 contains a hardware RNG. The RNG provides truly random numbers to enable fundamental security building blocks supporting stronger encryption, digital signing, and security protocols. Two versions of the FWH are available, called the 82802AB and 82802ACy. The AB version incorporates 512KB (4Mbit) of Flash BIOS memory, and the AC version incorporates a full 1MB (8Mbit) of BIOS ROM.

With the Intel 810 and 810E chipsets, Intel has done something that many in the industry were afraid of: It has integrated the video and graphics controller directly into the motherboard chipset with no means of upgrade. This means systems using the 810 chipset won't have an AGP slot and won't be capable of using conventional AGP video cards**.** For the low-end market for which this chipset is designed, lacking an AGP slot shouldn't be too much of a drawback. Higher-end systems, on the other hand, use the 815 or other chipsets that do support AGP slots. Intel calls the integrated interface Direct AGP, and it describes the direct connection between the memory and processor controllers with the video controller all within the same chip.

This probably dictates the future of mainstream PCs, which means the video card, as we know it, will be reserved only for midrange and higher-end systems, as well as gaming-oriented systems. With the 810 chipset, Intel has let it be known in a big way that it has entered the PC video business.

In fact, the theme with the 810 chipset is one of integration. The integrated video means no video cards are required; the integrated AC97 interface means that conventional modems and sound cards are not required. Plus, there is an integrated CMOS/Clock chip (in the ICH), and even the BIOS is integrated in the FWH chip. All in all, the 810 should be taken as a sign for things to come in the PC industry, which means more integration, better overall performance for low-end and mainstream systems, and less overall cost.

Intel Random Number Generator

The 8xx chipset series features the Intel RNG. The RNG is built into the 82802 FWH, which is the ROM BIOS component used on 8xx-based motherboards. The RNG provides software with true nondeterministic random numbers.

Most security routines, especially those providing authentication or encryption services, require random numbers for purposes such as key code generation. One method of cracking these types of codes is to predict the random numbers being used to generate the keys. Current methods that use system and user input as a seed to a conventional pseudorandom number generator have proven vulnerable to this type of attack. The Intel RNG uses thermal noise across a resistor contained in the FWH (that is, ROM BIOS in 8xx-based boards) to generate true nondeterministic, unpredictable random numbers. Therefore, "random" numbers generated by 8xx-series chipsets really are random.

Intel 815, 815E, and 815EP

Introduced in June 2000, the 815 and 815E chipsets are mainstream PC chipsets with integral video that is also upgradable via an AGP 4x slot. An 815EP version was introduced a few months later that lacks the integrated video for lower cost. The 815 chipsets are designed for Slot-1 or Socket-370 processors, such as the Celeron or Pentium III. These are the first chipsets from Intel designed to directly support PC133 SDRAM memory, allowing for a more affordable solution than other chipsets using RDRAM memory. Similar to the other 8xx series chipsets from Intel, the 815 uses hub architecture that provides a 266MB/sec connection between the main chipset components and does not share the PCI bus like the prior North/South Bridge designs.

Although three variations on the 815 chipset are available—including the regular 815, 815E, and 815EP—the only differences between them are in which I/O Controller Hub is used (ICH or ICH2) and whether the main chip includes integrated graphics. When the 82815 GMCH is combined with the 82801AA ICH, the result is called the 815 chipset. When the same GMCH is combined with the 82801BA ICH2, the result is called the 815E (see Figure 4.32).

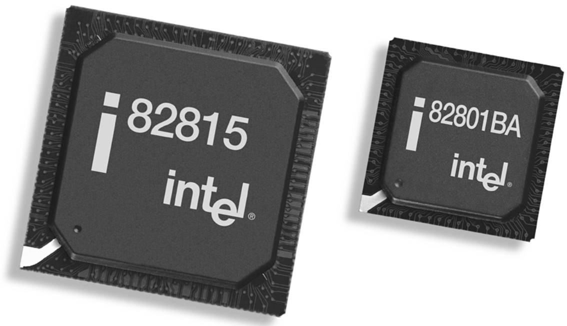

Figure 4.32 Intel 815E chipset showing the 82815 (GMCH) and 82801BA (ICH2) chips. *Photograph used by permission of Intel Corporation.*

When the 82815EP Memory Controller Hub (MCH, which lacks the integrated graphics) is combined with the ICH2, you have the 815EP chipset. The ICH2 provides an additional USB controller, dual Ultra ATA/100 controllers and support for a LAN/Modem/Sound card via the integrated Communications and Networking Riser (CNR) interface. All 815 chipsets support the following features:

- 66/100/133MHz system bus
- 266MB/sec hub interface
- ATA-100 (815E/EP) or ATA-66 (815)
- PC100 or PC133 CL-2 SDRAM
- Up to 512MB RAM
- Integrated Audio-Codec 97 (AC97) controller
- Low-power sleep modes
- RNG for stronger security products
- One (815) or two (815E/EP) integrated USB controllers with either two or four ports, respectively
- LPC bus for Super I/O and Firmware Hub (ROM BIOS) connection
- Elimination of ISA Bus

The 815 and 815E also support

- Integrated Intel AGP2x 3D graphics
- Efficient use of system memory for graphics performance
- Optional 4MB of dedicated display cache video memory
- Digital Video Out port compatible with DVI specification for flat panel displays
- Software MPEG-2 DVD playback with hardware motion compensation

The 815E/EP uses the ICH2, which is most notable for providing ATA-100 support, allowing 100MB/sec drive performance. Of course, few drives can really take advantage of this much throughput, but in any case, there won't be a bottleneck there. The other notable feature is having two USB controllers and four ports on board. This allows double the USB performance by splitting up devices over the two ports and can allow up to four connections before a hub is required.

Another important feature of the 815 is the integration of a fast Ethernet controller directly into the chipset. The integrated LAN controller works with one of three new physical layer components from Intel and enables three distinct solutions for computer manufacturers. These include

- Enhanced 10/100Mbps Ethernet with Alert on LAN technology
- Basic 10/100Mbps Ethernet
- 1Mbps home networking

These physical layer components can be placed directly on the PC motherboard (additional chips) or installed via an adapter that plugs into the CNR slot. The CNR slot and cards enable PC assemblers to build network-ready systems for several markets.

Although the 815/815E features essentially the same built-in AGP 2x 3D video that comes with the 810 chipset, the difference is upgradability. The video can be easily upgraded by adding a graphics performance accelerator (GPA) card (see Figure 4.33) or an AGP 4x card for maximum 3D graphics and video performance. The GPA card (also called the AGP Inline Memory Module, or AIMM) is essentially a high-performance video memory card that works in the AGP 4x slot and which improves the performance of the integrated video by up to 30%. For even more performance, you can install a full 4x AGP card in the AGP 4x slot, which disables the integrated video. By having the video integrated, very low-cost systems with reasonable video performance can be assembled. By later installing either the GPA or a full 4x AGP card, you can improve video performance up to 100% or more.

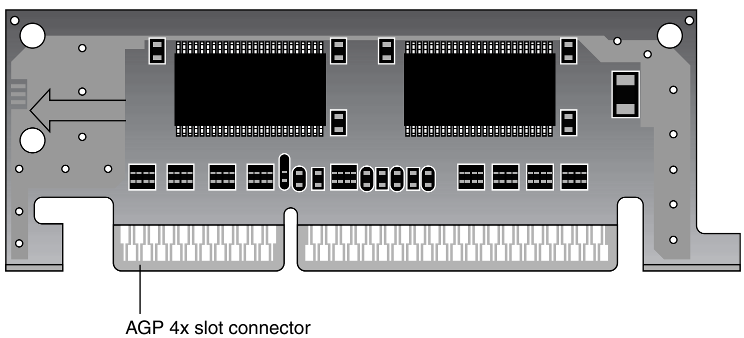

Figure 4.33 A typical 4MB GPA/AIMM module, which attaches to the AGP slot of a motherboard using the 815 or 815E chipset.

PC133 Memory Support

Another important feature of the 815 chipset is the support of PC133 memory. The 815 also uses PC100 memory if the higher-performance type is not available. With the PC133 support, Intel has also officially set a standard for PC133 memory that is higher than some of the PC133 memory currently on the market. This will no doubt create some confusion. To meet the Intel PC133 specification, the memory must support what is called 2-2-2 timing, sometimes also known as CAS-2 (column address strobe) or CL-2 timing. The numbers refer to the number of clock cycles for the following functions to complete:

- *Precharge command to Active command.* Charges the memory's storage capacitors to prepare them for data
- *Active command to Read command.* Selects rows and columns in memory array for reading
- *Read command to Data Out.* Reads data from selected rows and columns for transmission

Most PC133 memory on the market takes three cycles for each of these functions and would therefore be termed PC133 3-3-3, CAS-3, or CL-3 memory. Note that the faster PC133 CL-2 can be used in place of the slower CL-3 variety, but not the other way around.

As a result of the tighter cycling timing, PC133 CL-2 offers a lead-off latency of only 30ns, instead of the 45ns required by PC133 CL-3. This results in a 34% improvement in initial access due to the decreased latency.

With the improvements in the 815 chipset, it will likely be a popular chipset for the mainstream PC market that doesn't want to pay the higher prices for RDRAM memory. The 815 is essentially designed to replace the venerable 440BX chipset.

Intel 820 and 820E

The Intel 820 chipsets use the newer hub-based architecture like all the 800 series chips and were designed to support slot 1 or socket 370 processors, such as the Pentium III and Celeron (see Figure 4.34). The 820 chipset supports RDRAM memory technology, 133MHz system bus, and 4x AGP.

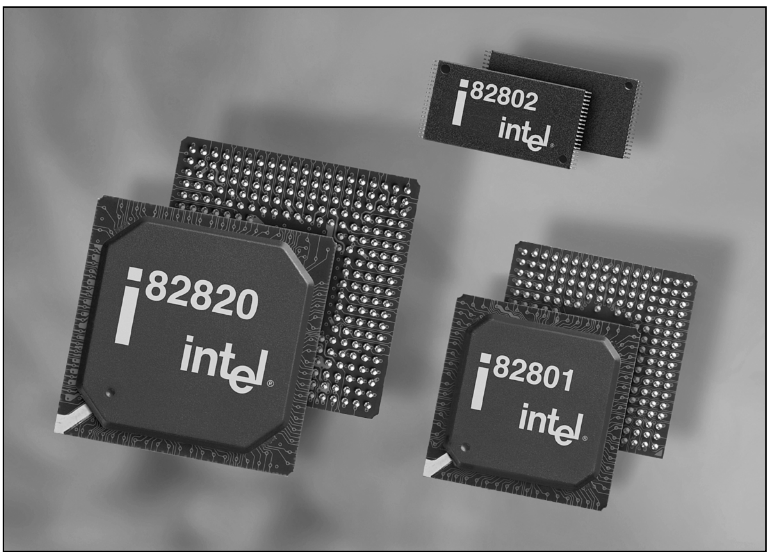

Figure 4.34 Intel 820 chipset showing the 82820 (MCH), 82801 (ICH), and 82802 (FWH) chips. *Photograph used by permission of Intel Corporation.*

The 82820 MCH provides the processor, memory, and AGP interfaces. Two versions are available: One supports a single processor (82820), whereas the other supports two processors (82820DP). Either is designed to work with the same 82801 ICH as used with the other 800 series chipsets, such as the 810 and 840. The 820 chipset also uses the 82802 FWH for BIOS storage and for the Intel RNG.

The connection between the MCH and ICH uses what is called the Intel Hub Architecture bus instead of the PCI bus as with prior North/South Bridge chipsets. The hub architecture bus provides twice the bandwidth of PCI at 266MB per second, enabling twice as much data to flow between them. The hub architecture bus also has optimized arbitration rules, allowing more functions run concurrently, as well as far fewer signal pins, reducing the likelihood of encountering or generating noise and signal errors.

The 820 chipset is designed to use RDRAM memory, which has a maximum throughput of up to 1.6GB/sec. The 820 supports PC600, PC700, and PC800 RDRAM, delivering up to 1.6GB/sec of theoretical memory bandwidth in the PC800 version. PC800 RDRAM is a 400MHz bus running double-clocked and transferring 16 bits (2 bytes) at a time (2 × 400MHz × 2 bytes = 1.6GB/sec). This compares to 800MB/sec for PC100 SDRAM, 1GB/sec for PC133 SDRAM, and 2.1GB/sec for DDR SDRAM. Two RIMM sockets are available to support up to 1GB of total system memory.

The AGP interface in the 820 enables graphics controllers to access main memory at AGP 4x speed, which is about 1GB per second—twice that of previous AGP 2x platforms. Figure 4.35 shows the 820 chipset architecture. Because the 820 was designed for midrange to higher-end systems, it does not include integrated graphics, relying instead on the AGP4x slot to contain a graphics card.

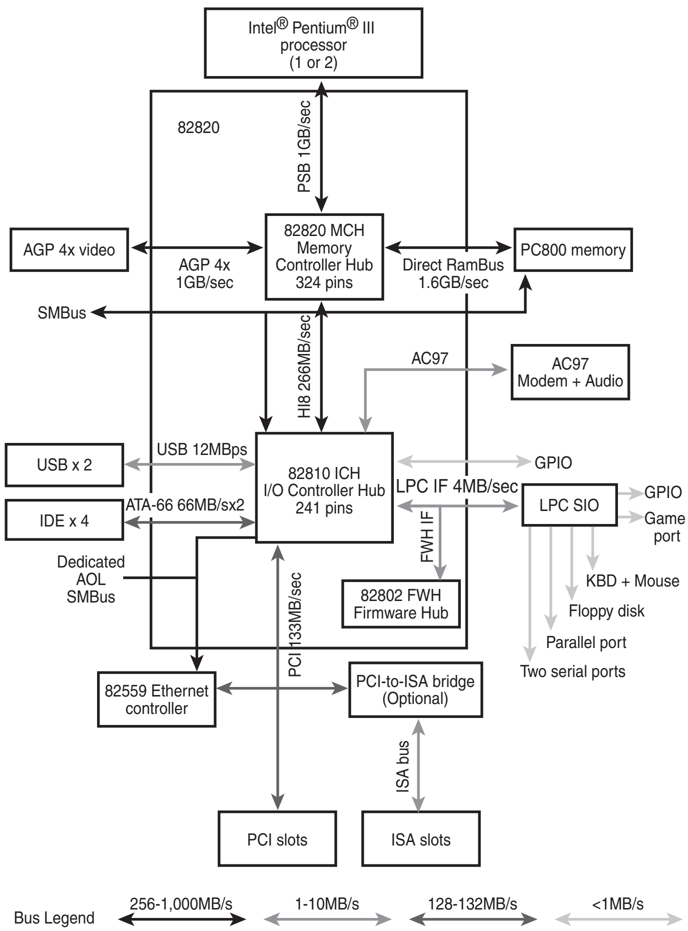

Figure 4.35 Intel 820 chipset architecture.

820 Chipset features include

- 100/133MHz processor bus
- Intel 266MB/sec hub interface
- PC800 RDRAM RIMM memory support
- AGP 4x support
- ATA-100 (820E) or ATA-66 interface
- Intel RNG
- LPC interface
- AC97 controller
- One (820) or two (820E) USB buses with either two or four ports, respectively

The 820 chipset consists of three main components with a few optional extras. The main component is the 82820 (single-processor) or 82820DP (dual-processor) MCH, which is a 324 BGA chip. That is paired with an 82801 ICH, which is a 241 BGA chip, and finally it has the 82802 FWH, which is really just a fancy Flash ROM BIOS chip. Optionally, there can be an 82380AB PCI-ISA bridge that is used only if the board is equipped with ISA slots.

The newer 820E version uses an updated 82801BA ICH2, which supports ATA-100 and incorporates dual USB controllers with two ports each, for a total of four USB ports.

820 Chipset MTH Bug

The 820 chipset is designed to support RDRAM memory directly. However, because the market still demanded lower-cost SDRAM, Intel created an RDRAM-to-SDRAM translator chip called the Memory Translator Hub (MTH). This enabled them to produce 820 chipset motherboards that supported SDRAM instead of the more expensive RDRAM.

Because the design of the MTH was proven defective, the chip (and any board using it) was simply discontinued. On May 10, 2000, Intel officially announced that it would replace any motherboards using the MTH with a new board lacking the component. The MTH translates signals from SDRAM memory to the Intel 820 chipset and is used only with motherboards utilizing SDRAM and the Intel 820 chipset; boards using RDRAM don't have an MTH and were not affected. Intel found electrical noise issues with the MTH that can cause some systems to intermittently reset, reboot, or hang. In addition, the noise issue can, under extreme conditions, potentially cause data corruption.

The MTH bug forced Intel to recall and replace more than a million motherboards in mid-2000, with new versions lacking the MTH and thus supporting only RDRAM memory. The final bill for this recall was reported at about $253 million, making this perhaps the most costly recall of computer components since the infamous Pentium math bug in 1994. I found it interesting that, due to the fact that Intel did more than $24.4 billion in sales the previous year, at least one article classified the cost of this recall as "chump change" to the chip giant!

Intel has an MTH I.D. Utility at `www.intel.com/support/mth`, which will tell you whether you have that component and whether your board is eligible for replacement, including a 128MB RDRAM RIMM. Again, note that the 820 chipset was really designed to support RDRAM as the native type of memory, and RDRAM-based systems are not affected because they don't use the memory translator hub component.

Intel 840

The Intel 840 is a high-end chipset designed for use in high-performance multiprocessor systems using slot 1, slot 2 (Xeon processor), or Socket 370 processors. The 840 chipset uses the same hub architecture and modular design as the rest of the 800 family chipsets, with some additional components enabling more performance. See Figure 4.36 for a photo of the Intel 840 chipset.

As with the other 800 series chipsets, the 840 has three main components:

- *82840 Memory Controller Hub*. Provides graphics support for AGP 2x/4x, dual RDRAM memory channels, and multiple PCI bus segments for high-performance I/O.
- *82801 I/O Controller Hub*. Equivalent to the South Bridge in older chipset designs, except it connects directly to the MCH component via the high-speed Intel Hub Architecture bus. The ICH supports 32-bit PCI, IDE controllers, and dual USB ports.
- *82802 Firmware Hub*. Basically an enhanced Flash ROM chip that stores system BIOS and video BIOS, as well as an Intel RNG. The RNG provides truly random numbers to enable stronger encryption, digital signing, and security protocols.

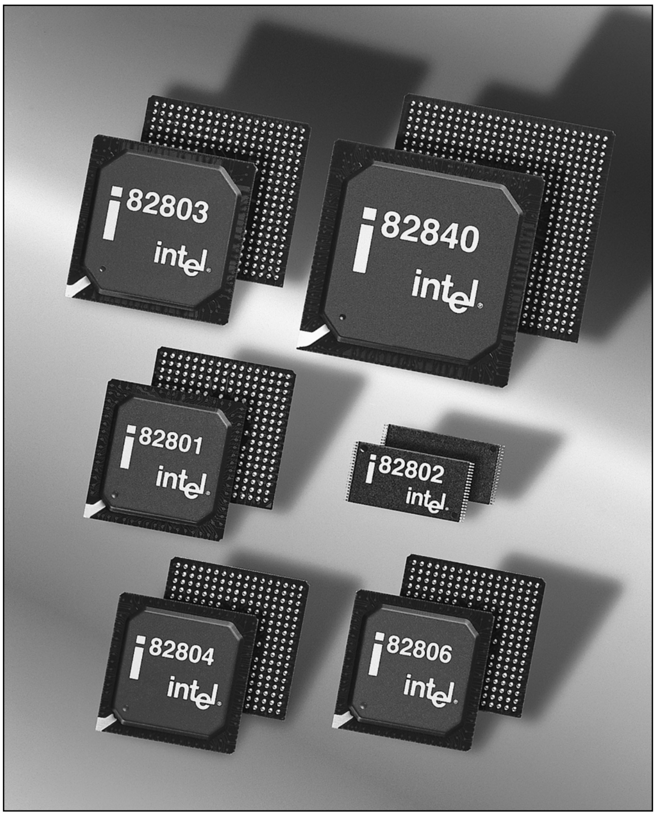

Figure 4.36 Intel 840 chipset showing the 82840 (MCH), 82801 (ICH), 82802 (FWH), 82803 (MRH-R), 82804 (MRH-S), and 82806 (P64H) chips. *Photograph used by permission of Intel Corporation.*

In addition to the core components, parts are available for scaling up to a more powerful design. Three additional components can be added:

- *82806 64-bit PCI Controller Hub (P64H).* Supports 64-bit PCI slots at speeds of either 33MHz or 66MHz. The P64H connects directly to the MCH using Intel Hub Architecture, providing a dedicated path for high-performance I/O. This is the first implementation of the 66MHz 66-bit PCI on a PC motherboard chipset, allowing for a PCI bus four times faster than the standard 32-bit 33MHz version.
- *82803 RDRAM-based Memory Repeater Hub (MRH-R).* Converts each memory channel into two memory channels for expanded memory capacity.
- *82804 SDRAM-based Memory Repeater Hub (MRH-S).* Translates the RDRAM protocol into SDRAM-based signals for system memory flexibility. This would be used only in 840 systems that supported SDRAM.

Figure 4.37 shows the 840 chipset architecture.

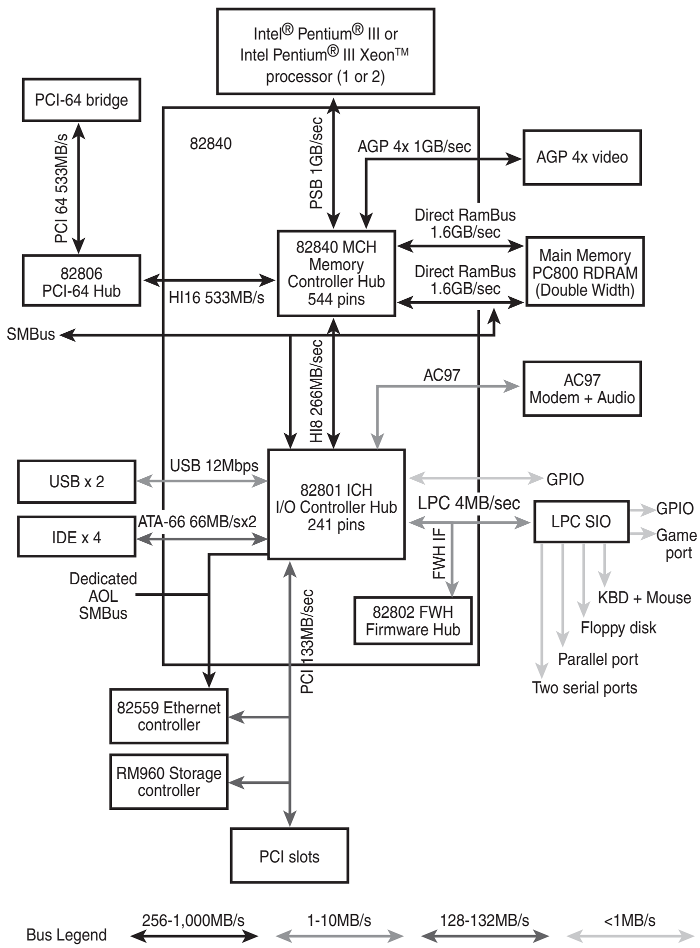

Figure 4.37 Intel 840 chipset architecture.

840 chipset features include

- 100/133MHz processor bus.
- Dual RDRAM memory channels, operating simultaneously, providing up to 3.2GB/sec memory bandwidth.
- 16-bit wide implementation of Intel Hub Architecture (HI16), which enables high-performance concurrent PCI I/O with the optional P64H component.
- AGP 4x.
- Prefetch cache, unique to the 840 chipset, enables highly efficient data flow and helps maximize system concurrency.
- Intel RNG (see the section "Intel Random Number Generator," earlier in this chapter).
- USB support.

Optionally, network interface and RAID controller interface chips can be added as well.

Intel 850

The Intel 850 is the first chipset for the Intel Pentium 4 processor and thus is also the first chipset to support the NetBurst microarchitecture. The 850 is designed for high-performance desktop computers and workstations and uses the same hub architecture and modular design as the rest of Intel's 8xx family of chipsets. See Figure 4.38 for a photo of the Intel 850 chipset.

The 850 has two main components, down from three in earlier 800-series chipsets:

- *82850 Memory Controller Hub*. Provides support for dual 400MHz RDRAM memory channels with a 3.2GBps bandwidth and a 100MHz system bus. The 82850 MCH also supports 1.5V AGP 4x video cards at a bandwidth exceeding 1GBps.
- *82801BA I/O Controller Hub 2*. The ICH2 (an enhanced version of the 82801 used by other 800-series chipsets) supports 32-bit PCI rev. 2.2, dual UDMA 33/66/100 IDE host adapters, four USB ports, an integrated LAN controller, six-channel AC-97 audio/modem codec, FWH interface support, SMBus support, and Alert on LAN and Alert on LAN 2 support.

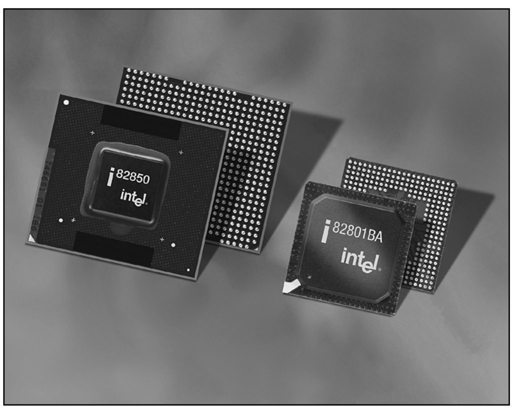

Figure 4.38 The Intel 850 chipset. *Photo used by permission of Intel Corporation.*

Optionally, the Intel 82562ET/82562EM Platform LAN communication chips can be added to the 850 chipset to provide support for 10BASE-T and Fast Ethernet networking, building on the LAN features in the 82801BA ICH2 chip.

The 850 chipset, like most recent Intel and non-Intel chipsets, also supports the CNR card for integrated audio, modem, and network capabilities. See Figure 4.39 for a diagram of the 850's chipset architecture.

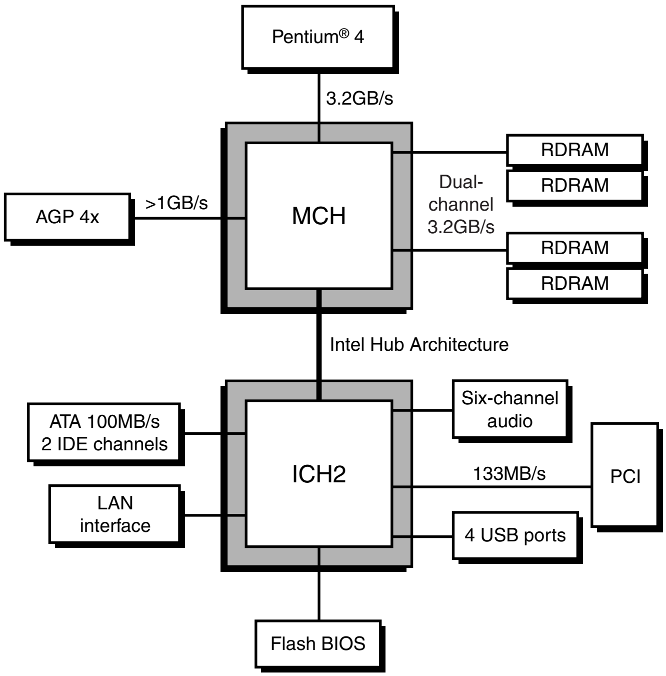

Figure 4.39 Architecture of the Intel 850 chipset.

Intel 860

The Intel 860 is a high-performance chipset designed for the newest Socket 602 Xeon processors for DP workstations. The 860 uses the same ICH2 as the Intel 850 but uses a different MCH—the 82860, which supports one or two Socket 602 ("Foster") Xeon processors. The other major features of the 82860 are similar to those of the 82850, including support for dual 400MHz RDRAM memory channels with a 3.2GBps bandwidth and a 100MHz system bus. The 82860 MCH also supports 1.5V AGP 4x video cards at a bandwidth exceeding 1GBps.

The 860 chipset uses a modular design, in which its two core chips can be supplemented by the 82860AA (P64H) 66MHz PCI Controller Hub and the 82803AA MRHR. The 82860AA supports 64-bit PCI slots at either 33MHz or 66MHz, and the 82803AA converts each RDRAM memory channel into two, which doubles memory capacity.

Third-Party (Non-Intel) P6-Class Chipsets

Several companies produce chipsets designed to support P6-class processors, including ALi, VIA Technologies, and SiS. The following sections discuss the offerings from these companies.

Acer Laboratories, Inc.

ALi has a variety of chipsets for the P6-class processors. They are discussed in the following sections.

Aladdin Pro II

The Acer Labs Aladdin Pro II M1621 is a two-chip set for P6 (Pentium Pro and Pentium II) Slot 1 processors consisting of two BGA package chips, the 456-pin BGA package M1621 North Bridge, and either the M1533 or M1543 South Bridge. The M1621 North Bridge includes an AGP, memory, and I/O controller and a data path with multiport buffers for data acceleration. It can support multiple Pentium II processors with bus speeds of 60MHz, 66MHz, and 100MHz. This chipset is equivalent to the 440BX chipset from Intel.

The integrated memory controller supports FPM, EDO, and SDRAM with a total capacity of up to 1GB (SDRAM) or 2GB (EDO). ECC memory is supported, enabling use in mission-critical or fileserver applications. Memory timing is x-1-1-1-1-1-1-1 in back-to-back SDRAM reads or x-2-2-2-2-2-2-2 in back-to-back EDO reads.

The M1621 supports AGP v1.0, in both 1x and 2x modes, and is fully compliant with PCI rev. 2.1, enabling concurrent PCI operations. The M1621 can be used with either the M1533 South Bridge or M1543 South Bridge/Super I/O combo chip.

The M1533 South Bridge includes the following features:

- PCI-to-ISA bridge
- Built-in keyboard/mouse controller
- Enhanced Power Management, featuring ACPI
- Two-port USB interface
- Dual-channel Ultra-DMA/33 IDE host adapter
- 328-pin BGA package

M1543 includes all features in the 1533 plus fully integrated Super I/O, including a floppy disk controller, two high-speed serial ports, and one multimode parallel port.

Aladdin Pro 4

The Acer Labs Aladdin Pro 4 for P6 (Pentium II/III/Celeron) Slot 1 or Socket 370 processor is a two-chip set consisting of two chips: the 508-pin BGA M1641 or M1641B North Bridge and the M1535D or M1535D+ South Bridge.

The M1641 North Bridge supports processor bus speeds of 66MHz, 100MHz, or 133MHz. The M1641B is a double–data-rate version supporting DDR SDRAM at speeds up to 266MHz.

The M1641/M1641B's integrated memory controller supports EDO, SDRAM, or VC-SDRAM with a total capacity of 1.5GB. ECC memory is supported, enabling this chipset to be used in file-server or mission-critical applications. Memory timing is x-1-1-1-1-1-1-1 in back-to-back SDRAM reads.

The M1641/M1641B supports AGP 4x video, PCI 2.2, and up to six PCI masters beyond the North Bridge and PCI bridge. They also support Dark Green power management, including Power On Suspend, Suspend to RAM, PCI Bus CLKRUN, and Dynamic Clock Stop.

The M1535D South Bridge includes the following features:

- Built-in keyboard/mouse controller
- Enhanced Power Management, featuring ACPI and PCI Power Management
- Four-port USB interface
- Dual-channel Ultra-DMA/66 IDE host adapter

- Integrated Super I/O including a floppy disk controller, two high-speed serial ports, one multi-mode parallel port, and an IrDA serial port
- Built-in Wavetable audio with Sound Blaster 16 compliance
- 'AC 97 soft modem compatible
- 352-pin BGA package

Aladdin TnT2

The Acer Labs Aladdin TnT2 for P6 (Pentium II/III/Celeron) Slot 1 or Socket 370 processor is a two-chip set consisting of two chips: the 556-pin BGA M1631 North Bridge and either the M1543C or M1535D South Bridge.

The M1631 North Bridge integrates nVidia's popular TnT2 3D graphics engine with the Aladdin Pro 4 chipset. It supports processor bus speeds of 66MHz, 100MHz, or 133MHz.

The integrated memory controller supports EDO, SDRAM, or VC-SDRAM with a total capacity of 1.5GB. ECC memory is supported, allowing this chipset to be used in file-server or mission-critical applications. Memory timing is x-1-1-1-1-1-1-1 in back-to-back SDRAM reads.

The M1641 supports PCI 2.2 and up to six PCI masters beyond the North Bridge and PCI-to-ISA bridge; it also supports Dark Green power management, including Power On Suspend, Suspend to RAM, PCI Bus CLKRUN, and Dynamic Clock Stop.

The integrated TnT2 3D graphics engine features a 128-bit graphic pipeline, DirectX-compatible 3D acceleration, 32-bit 3D True-Color rendering, multitextured bump maps, environment maps, and the other features of the nVidia TnT2 chipset. Motherboards using this chipset can use UMA shared memory or can provide 4MB, 8MB, or 16MB of SDRAM or SGRAM for the exclusive use of the graphics engine. The M1641 supports digital flat panel, TV-out, and video capture.

The M1543C South Bridge includes the following features:

- PCI-to-ISA bridge
- Built-in keyboard/mouse controller
- Enhanced Power Management, featuring ACPI and PCI Power Management
- Three-port USB interface
- Dual-channel Ultra-DMA/66 IDE host adapter
- Integrated Super I/O including a floppy disk controller, two high-speed serial ports, one multi-mode parallel port, and an IrDA serial port
- 330-pin BGA package

Aladdin Pro 5 and Pro 5T

The Acer Labs Aladdin Pro 5 for P6 (Pentium II/III/Celeron) Slot 1 or Socket 370 processor is a two-chip set consisting of two chips: the 528-pin BGA M1651 North Bridge and the M1535D+ or M1535D South Bridge. The Aladdin Pro 5M is a mobile version for notebook computers that uses the M1535 or M1535+ South Bridge.

The M1651 North Bridge supports SDRAM and processor bus speeds of 66MHz, 100MHz, 133MHz as well as DDR SDRAM at speeds of 200MHz or 266MHz. It supports up to 3GB of RAM but does not support ECC. Memory timing is x-1-1-1-1-1-1-1 in back-to-back SDRAM reads. Because the M1651 supports both conventional and DDR SDRAM, it enables system manufacturers to use the same chipset for both memory types.

The M1651 supports AGP 4x video, PCI 2.2, up to six PCI masters beyond the North Bridge and PCI bridge, and ACPI and Legacy green power management. In addition, it supports PCI Mobile CLKRUN# and AGP Mobile BUSY#/STOP#.

The Aladdin Pro 5T uses the M1651T North Bridge, which has been redesigned to comply with the requirements of the new .13 micron Pentium III Tualatin processors released in May 2001. Otherwise, it supports the same features as the regular M1651 North Bridge.

The M1535D+ South Bridge includes the following features:

- Built-in keyboard/mouse controller
- Enhanced Power Management, featuring ACPI and PCI Power Management with support for power management states G0–G3
- Six-port USB interface with support for USB keyboard and mouse
- Dual-channel Ultra-DMA/100 IDE host adapter
- Integrated Super I/O including a floppy disk controller, two high-speed serial ports, one multi-mode parallel port, and an IrDA serial port
- Built-in PCI audio with DirectSound 3D, MIDI, and Sound Blaster 16 compliance; SPDIF interface for digital audio
- Software modem compliance
- 352-pin BGA package

VIA Technologies

VIA Technologies has a variety of chipsets for the P6 processors. They are discussed in the following sections.

Apollo Pro266

The VIA Apollo Pro 266 is a high-performance North/South Bridge chipset designed to support Socket 370 processors, including the Pentium III, Celeron, and VIA's own C3. The Apollo Pro 266 is a development of the Apollo Pro 133A with provisions for both DDR200/266MHz RAM, as well as PC100/133 SDRAM and VC-SDRAM.

Features of the Apollo Pro266 include

- AGP 2x/4x graphics bus support
- 133/100/66MHz processor bus support
- PC-100/133 SDRAM and PC200/266 DDR SDRAM memory interface
- ATA-100 IDE interface
- Support for six USB ports
- Integrated AC97 six-channel audio
- Integrated MC97 modem
- Integrated 10/100 BASE-T Ethernet and 1/10MHz Home PNA networking
- Hardware monitoring
- ACPI/On Now! Power management

The VIA Apollo Pro266 chipset is a two-chip set consisting of the 552-pin BGA VT8633 North Bridge Controller and the 352-pin BGA VT82C686B South Bridge Controller.

Apollo Pro133A

The VIA Apollo Pro133A chipset is a North/South Bridge chipset designed to support Slot 1 and Socket 370 processors such as the Intel Pentium III, Intel Celeron, and VIA Cyrix III. The Apollo Pro133A is based on the previous Pro133 with even more high-end features added.

Features of the Apollo Pro133A include

- AGP 4x graphics bus support
- Support for one or two processors
- 133/100/66MHz processor bus support
- PC-133 SDRAM memory interface
- ATA-66 interface
- Support for four USB ports
- AC97 link for audio and modem
- Hardware monitoring
- Power management

The VIA Apollo Pro133A chipset is a two-chip set consisting of the VT82C694X North Bridge Controller and a choice of VT82C596B or VT82C686A South Bridge Controllers.

ProSavage PM133

The VIA ProSavage PM133 integrates S3 Graphics' S3 Savage 4 and S3 Savage 2000 3D and 2D graphics engines with the Apollo Pro 133A chipset. The major features of the chipset are the same as for the Apollo Pro 133A, with the following additions:

- 2MB to 32MB shared memory architecture integrated with Savage 4 3D and Savage 2000 2D video
- Z-buffering, 32-bit true-color rendering, massive 2K by 2K textures, single-pass multiple textures, sprite antialiasing, and other 3D features
- Support for DVD playback, DVI LCD displays, and TV-out
- PCI 2.2 compliance

An optional AGP 4x interface allows the integrated AGP 4x video to be upgraded with an add-on card if desired. This two-chip set consists of the VT8605 North Bridge and VT8231 South Bridge.

The VT8231 South Bridge integrates the Super I/O and supports the LPC interface.

Apollo Pro133

The VIA Apollo Pro133 was the first chipset on the market designed to support PC-133 SDRAM memory. This chipset supports Slot 1 and Socket 370 processors, such as the Intel Pentium III, Intel Celeron, and VIA Cyrix III processors.

Key features include the following:

- Support for AGP 2x graphics bus
- Support for 133/100/66MHz processor bus
- PC-133 SDRAM memory interface
- Support for 1.5GB of RAM

- ATA-66 interface
- Support for four USB ports
- AC97 link for audio and modem
- Hardware monitoring
- Power management

The VIA Apollo Pro133 is a two-chip set consisting of the VT82C693A North Bridge Controller and a choice of VT82C596B or VT82C686A South Bridge Controllers.

Apollo KLE133

The VIA Apollo KLE133 (previously known as the PM601) chipset is a highly integrated chipset platform designed for the value PC and Internet appliance market. As such, this chipset has a built-in Trident Blade3D graphics engine and 10/100 Ethernet. The KLE133 is designed for Slot 1 and Socket 370 processors, such as the Pentium III, Celeron, and VIA C3.

Key features include the following:

- Support for AGP 2x
- Integrated Trident Blade3D AGP graphics engine
- 66/100/133MHz processor bus
- Support for PC-133 SDRAM memory
- Integrated 10/100 Ethernet
- Support for AC97 audio, MC97 modem, Super I/O, and hardware monitoring
- Four USB ports
- Support for ATA-66
- Advanced power management

The VIA Apollo KLE133 is a two-chip set consisting of the VT8601 North Bridge Controller and the VT82C686A South Bridge Controller.

Apollo Pro

The Apollo Pro is a high-performance chipset for Slot 1 mobile and desktop PC systems; it can also support the Socket 8 Pentium Pro processor. The Apollo Pro includes support for advanced system power management capability for both desktop and mobile PC applications, PC100 SDRAM, AGP 2x mode, and multiple CPU/DRAM timing configurations. The Apollo Pro chipset is comparable in features to the 440BX and PIIX4e chipsets from Intel and represents one of the first non-Intel chipsets to support the Socket 1 architecture.

The VIA Apollo Pro consists of two devices—the VT82C691 North Bridge chip and the VT82C596, a BGA-packaged South Bridge with a full set of mobile, power-management features. For cost-effective desktop designs, the VT82C691 can also be configured with the VT82C586B South Bridge.

The VT82C691 Apollo Pro North Bridge supports all Slot 1 (Intel Pentium II) and Socket 8 (Intel Pentium Pro) processors. The Apollo Pro also supports the 66MHz external bus speed and the newer 100MHz CPU external bus speed required by the 350MHz and faster Pentium II processors. AGP v1.0 and PCI 2.1 are also supported, as are FPM, EDO, and SDRAM. Various DRAM types can be used in mixed combinations in up to eight banks and up to 1GB of DRAM. EDO memory timing is 5-2-2-2-2-2-2-2 for back-to-back accesses, and SDRAM timing is 6-1-1-1-2-1-1-1 for back-to-back accesses.

The VT82C596 South Bridge supports both ACPI and APM and includes an integrated USB controller and dual Ultra DMA-66 EIDE ports.

Apollo Pro Plus

The VIA Apollo Pro Plus is a high-performance chipset for Slot 1/Socket 370 mobile and desktop PC systems.

Features include

- 66/100MHz CPU bus
- AGP 1x
- PCI 2.1 compliant
- Support for eight banks up to 1GB PC-100 SDRAM
- Support for both ACPI and legacy (APM) power management
- Integrated USB controller
- Ultra DMA-33 controller

The Apollo Pro consists of two chips: a VT82C693 North Bridge paired with either the VT82C596A mobile South Bridge or the VT82C686A Super South Bridge.

Silicon Integrated Systems Chipsets for P6 Processors

Silicon Integrated Systems has a variety of chipsets for the P6-class processors. They are discussed in the following sections.

SiS633/635 Family

The SiS633/635 family is a series of high-performance single-chip chipsets that support the Pentium III and Celeron Socket 370 processors. T-series chipsets also support the new .13 micron Pentium III Tualatin processors released in May 2001.

The SiS633 and SiS633T chipsets support PC133 SDRAM, whereas the SiS635 and SiS635T chipsets support PC133 SDRAM, DDR266 DDR SDRAM, or a mixture of PC133 and DDR266 SDRAM. All chipsets in the family support the following features:

- Integrated 4x AGP
- Up to six PCI masters
- UDMA/100 IDE host adapters
- 1.5GB RAM
- Six USB ports
- AC97 audio and AMR support

SiS635/635T also support ACR or CNR riser technology and integrate 10/100 BASE-T Ethernet and 1/10MHz Home PNA networking.

These chips use a 677-pin BGA package.

SiS630 Family

The SiS630 is a high-performance, low-cost single-chip set with integrated 2D/3D graphics and support for Slot 1 and Socket 370 processors such as the Pentium III, Celeron, and Cyrix III.

The integrated video is based on a 128-bit graphic display interface with AGP 4x performance. In addition to providing a standard analog interface for CRT monitors, the SiS630 also provides the digital flat panel port (DFP) for a digital flat panel monitor. An optional SiS301 Video Bridge supports NTSC/PAL TV output.

The SiS630 also includes integrated 10/100Mb Fast Ethernet, as well as an AC97-compliant interface that comprises a digital audio engine with 3D-hardware accelerator, on-chip sample rate converter, and professional wavetable along with separate modem DMA controller. SiS630 also incorporates the LPC interface for attaching newer Super I/O chips and a dual USB host controller with four USB ports.

Features of the SiS630 include

- Support for Intel/AMD/Cyrix/IDT Pentium CPU processor bus at 66/83/90/95/100MHz
- Integrated 2MB Level 2 cache controller
- PC133 SDRAM support
- Meets PC99 requirements
- PCI 2.2 compliant
- Ultra DMA66/33 support
- Integrated AGP 2x 2D/3D Video/Graphics Accelerator
- Support for digital flat panel
- Hardware DVD decoding
- Built-in secondary CRT controller for independent secondary CRT, LCD, or TV digital output
- Low Pin Count interface
- Advanced PCI H/W Audio and S/W Modem
- Meets ACPI 1.0 requirements
- PCI Bus Power Management Interface Spec. 1.0
- Integrated keyboard/mouse controller
- Dual USB controller with five USB ports
- Integrated 10/100Mb/sec Ethernet controller

The SiS630E chip is almost identical in its feature set but doesn't support the secondary CRT controller (also called the video bridge). The SiS630S chip adds support for an AGP slot and the new Advanced Communication Riser to the basic SiS630 features. What's really amazing about the SiS630 family is that all these features are combined into a single chip that's not much larger than the North Bridge used by other chipsets.

SiS620/5595

The SiS620/5595 is a North/South Bridge chipset with integrated video that supports Slot 1 or Socket 370 processors.

Features include

- 66/100MHz processor bus
- Support for PC-100 SDRAM memory
- Support for Ultra DMA 33/66
- PCI 2.2 compliant

- Integrated AGP 3D graphics accelerator
- Support for digital flat panel port for LCD panel

SiS600/5595 and 5600/5595

The SiS600/SiS5595 is a slot-1 North/South Bridge chipset designed for lower-cost systems.

Features include

- 66/100MHz processor bus
- PC-100 SDRAM with ECC
- AGP 2x
- Ultra DMA/33
- Two USB ports
- Advanced Configuration and Power Interface revision 1.0

Athlon/Duron Chipsets

The Athlon and Duron are Slot A and Socket A chips made by AMD. Although similar to the Pentium III and Celeron, the AMD chips use a different interface and require different chipsets. AMD was originally the only supplier for Athlon chipsets, but VIA Technology, Acer Labs, and SiS are now providing a large number of chipsets with a wide range of features. These chipsets are covered in the following sections.

AMD Chipsets for Athlon/Duron Processors

AMD makes two chipsets for Athlon and Duron processors: the AMD-750 and AMD-760. The major features of these chipsets are compared in Table 4.12 and described in greater detail in the following sections.

Table 4.12 AMD Athlon/Duron Processor Chipsets Using North/South Bridge Architecture

Chipset	AMD-750	AMD-760
Codename	Irongate	None
Date introduced	Aug. 1999	Oct. 2000
Part numbers	AMD-751	AMD-761
Bus speed	200MHz	200/266MHz
Supported processors	Athlon/Duron	Athlon/Duron
SMP (dual CPUs)	No	Yes
Memory types	SDRAM	DDR SDRAM
Memory speed	PC100	PC1600/PC2100
Parity/ECC	Both	Both
Maximum memory	768MB	2GB buffered, 4GB registered
PCI support	2.2	2.2
AGP support	AGP 2x	AGP 4x
South Bridge	AMD-756	AMD-766
ATA/IDE support	ATA-66	ATA-100

Table 4.12 Continued

Chipset	AMD-750	AMD-760
USB support	1C/4P	1C/4P
CMOS/clock	Yes	Yes
ISA support	Yes	No
LPC support	No	Yes
Power management	SMM/ACPI	SMM/ACPI

SMP = Symmetric multiprocessing (dual processors)
SDRAM = Synchronous dynamic RAM
DDR-SDRAM = Double data rate SDRAM
ECC = Error correcting code
PCI = Peripheral component interconnect
AGP = Accelerated graphics port
ATA = AT attachment (IDE) interface
USB = Universal serial bus
ISA = Industry Standard Architecture
LPC = Low pin count bus

AMD 750

AMD's first chipset for its own Slot A and Socket A processors, called the AMD-750, is a traditional North/South Bridge design specifically for the Athlon and Duron processors. The AMD-750 chipset consists of the AMD-751 North Bridge and the AMD-756 South Bridge.

The AMD-751 system controller connects between the AMD Athlon processor bus to the processor and also features the memory controller, AGP 2x controller, and PCI bus controller. The AMD-756 South Bridge includes a PCI-to-ISA bridge, USB controller interface, and ATA 33/66 controller.

The AMD-750 chipset includes the following features:

- AMD Athlon 200MHz processor bus
- PCI 2.2 bus with up to six masters
- AGP 2x
- PC-100 SDRAM with ECC
- Up to 768MB of memory
- ACPI power management
- ATA-33/66 support
- USB controller
- ISA bus support
- Integrated 256-byte CMOS RAM with clock
- Integrated keyboard/mouse controller

AMD 760

The AMD-760 chipset was introduced in October 2000 and is notable as the first chipset supporting DDR SDRAM memory. The AMD-760 chipset consists of the AMD-761 system controller (North Bridge) in a 569-pin plastic ball-grid array package and the AMD-766 peripheral bus controller (South Bridge) in a 272-pin PBGA package. See Figure 4.40 for details of the 760's block diagram.

The AMD-761 North Bridge features the AMD Athlon system bus, DDR-SDRAM system memory controller with support for either PC1600 or PC2100 memory, AGP 4x controller, and PCI bus controller. The 761 allows for 200MHz or 266MHz processor bus operation and supports the newer Athlon chips that use the 266MHz processor (also called front-side) bus.

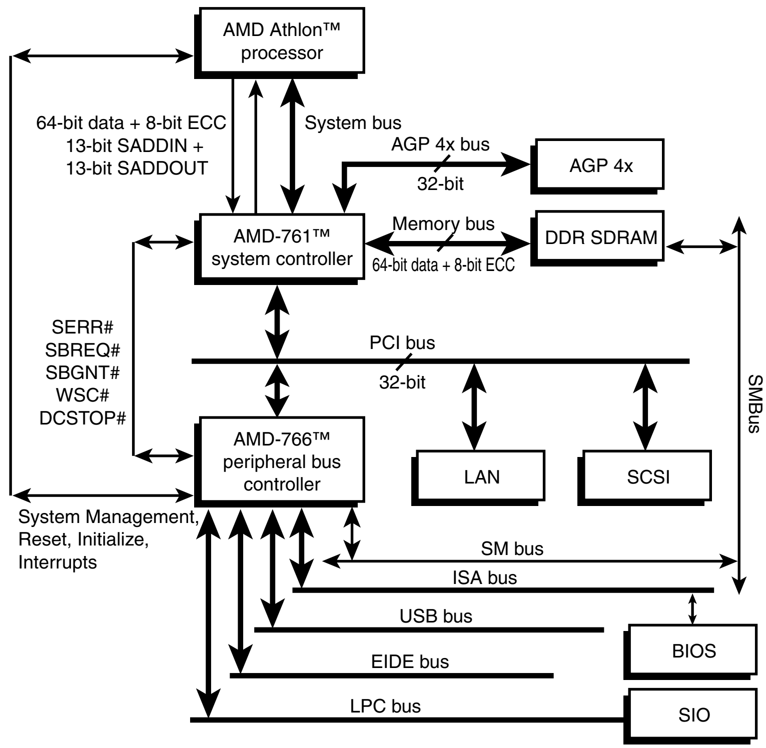

Figure 4.40 AMD 760 chipset block diagram.

The AMD-766 South Bridge includes a USB controller, dual UDMA/100 ATA/IDE interfaces, and the LPC bus for interfacing newer Super I/O and ROM BIOS components.

The AMD-760 chipset includes the following features:

- AMD Athlon 200/266MHz processor bus
- Dual processor support
- PCI 2.2 bus with up to six masters
- AGP 2.0 interface that supports 4x mode
- PC1600 or PC2100 DDR SDRAM with ECC
- Support for a maximum of 2GB buffered or 4GB registered DDR SDRAM
- ACPI power management
- ATA-100 support
- USB controller
- LPC bus for Super I/O support

VIA Chipsets

VIA Technologies, Inc., is the largest chipset and processor supplier outside of Intel and AMD. Originally founded in 1987, VIA is based in Taipei, Taiwan, and is the largest integrated circuit design firm on the island. VIA is a fabless company, which means they farm out the manufacturing to other companies with chip foundry capability. Although they are best known for their chipsets, in 1999 VIA purchased the Cyrix processor division from National Semiconductor and the Centaur processor division from IDT, respectively, thereby becoming a supplier of processors in addition to chipsets. VIA has also formed a joint venture with SonicBLUE (formerly S3) as a means of integrating graphics capabilities into various chipset products. This joint venture is known as S3 Graphics, Inc.

VIA makes chipsets for Intel, AMD, and Cyrix (VIA) processors. Table 4.13 lists the Athlon/Duron chipsets offered by VIA. These chipsets are discussed in the following sections.

Table 4.13 VIA Athlon/Duron Processor Chipsets Using North/South Bridge Architecture

Chipset	Apollo KX133	Apollo KT133	Apollo KT133A	Apollo KT266	Apollo KLE133
Introduced	Aug. 1999	Jun. 2000	Dec. 2000	January 2001	March 2001
North Bridge	VT8371	VT8363	VT8363A	VT8363	VT 8361
Processor support	Athlon	Athlon/Duron	Athlon/Duron	Athlon/Duron	Duron
CPU interface	Slot-A	Socket-A (462)	Socket-A (462)	Socket-A (462)	Socket-A (462)
CPU FSB	200MHz	200MHz	200/266MHz	200/266MHz	200/266MHz
AGP	4x	4x	4x	4x	Integrated AGP 2x
PCI	2.2	2.2	2.2	2.2	2.2

CMOS/Clock	Yes	Yes	Yes	Yes	Yes

VIA Technologies Apollo KX133

The VIA Apollo KX133 chipset brings AGP 4x, PC133, a 200MHz FSB, and ATA-66 technologies to the AMD Athlon processor platform, exceeding the performance of AMD's own 750 chipset. It was the first chipset to support AGP 4x.

Key features include the following:

- 200MHz processor bus
- AGP 4x graphics bus
- PC133 SDRAM memory
- 2GB maximum RAM
- ATA-66 support
- Four USB ports
- AC97 link for audio and modem
- Hardware monitoring
- Power management

The VIA Apollo KX133 is a two-chip set consisting of the VT8371 North Bridge controller and the VT82C686A South Bridge controller.

VIA Technologies Apollo KT133 and KT133A

The VIA Apollo KT133/A chipsets are designed to support the AMD Athlon and Duron processors in Socket-A (462) form. Based on the prior KX133 chipset, the KT133/A differ mainly in their support for Socket-A (462) over the previous Slot-A processor interface.

The VIA Apollo KT133 and KT133A are both two-chip sets consisting of the VT8363 North Bridge and the VT82C686A South Bridge (KT133) or the VT8363A North Bridge and the VT82C686B South Bridge (KT133A).

Both the KT133 and KT133A support the following standard features:

- Athlon/Duron Socket-A (462) processors
- 200MHz CPU (front-side) bus
- AGP 4x
- 2GB RAM maximum
- PC100/PC133MHz SDRAM
- PCI 2.2
- ATA-66
- USB support
- AC-97 audio
- Integrated Super I/O
- Integrated hardware monitoring
- ACPI power management

The KT133A (VT8363A North Bridge with VT82C686B South Bridge) adds the following exclusive features:

- 266MHz CPU (front-side) bus
- ATA-100

ProSavage PM133

The VIA ProSavage PM133 integrates S3 Graphics' S3 Savage 4 and S3 Savage 2000 3D and 2D graphics engines with the Apollo Pro KT133 chipset. The major features of the chipset are the same as for the Apollo Pro KT133, with the following additions:

- 2MB–32MB shared memory architecture integrated with Savage 4 3D and Savage 2000 2D video
- Z-buffering, 32-bit true-color rendering, massive 2K by 2K textures, single-pass multiple textures, sprite antialiasing, and other 3D features
- Support for DVD playback, DVI LCD displays, and TV-out
- PCI 2.2 compliance

An optional AGP 4x interface enables the integrated AGP 4x video to be upgraded with an add-on card if desired. This two-chip chipset consists of the VT8365 North Bridge and VT8231 South Bridge.

The VT8231 South Bridge integrates the Super I/O and supports the LPC interface.

Silicon Integrated Systems Chipsets for AMD Athlon/Duron Processors

SiS has a variety of chipsets for the Athlon and Duron processors. They are discussed in the following sections.

SiS733 and SiS735

The SiS733 and SiS735 are high-performance single-chip sets that support the AMD Athlon and Duron Socket A processors. Similar to other SiS single-chip sets, the SiS733 and SiS735 incorporate the features of a traditional North Bridge, South Bridge, and Super I/O chip into a single chip.

The SiS733 supports PC133 SDRAM and uses a 682-pin BGA package. The SiS735 supports either PC133 or DDR266 SDRAM and also integrates 10/100 Fast Ethernet and HomePNA 1Mbps/10Mbps Home Network interfaces. The SiS735 also uses a 682-pin BGA package.

The SiS733 and SiS735 share the following features:

- Support for 4x AGP
- Up to six PCI masters
- Dual UDMA/100 IDE host adapters
- 1.5GB RAM maximum
- Six USB ports
- AC-97 audio and AMR support
- Integrated RTC
- Low Pin Count interface for support of MIDI, joystick, and legacy BIOS devices
- PC2001 compliant

Figure 4.41 illustrates the SiS733's block diagram.

SiS730S

The SiS730S is a high-performance, low-cost, single-chip chipset with integrated 2D/3D graphics and support for Socket A versions of the AMD Athlon and Duron.

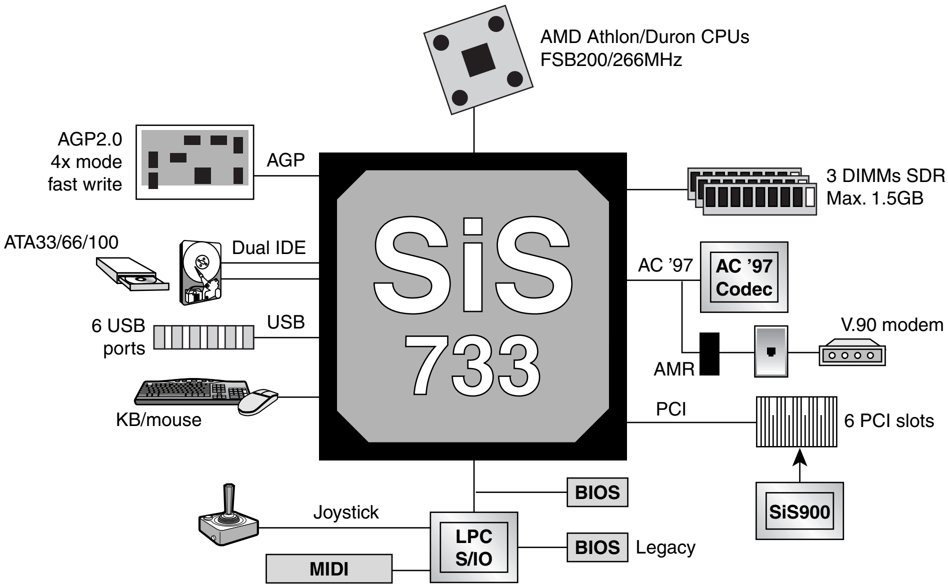

Figure 4.41 The SiS733 provides a single control interface for all major motherboard functions.

The integrated video is based on a 128-bit graphic display interface with AGP 4x performance. In addition to providing a standard analog interface for CRT monitors, the SiS730S also provides the DFP for a digital flat panel monitor. An optional SiS301 Video Bridge supports NTSC/PAL TV output. The SiS730S supports an AGP 4x slot, enabling users to upgrade to a separate AGP card in the future.

The SiS730S also includes integrated 10/100Mb Fast Ethernet as well as an AC-97–compliant interface that comprises a digital audio engine with 3D-hardware accelerator, on-chip sample rate converter, and professional wavetable along with separate modem DMA controller. SiS730S also incorporates the LPC interface for attaching newer Super I/O chips and a dual USB host controller with six USB ports. The SiS730S can also be used with ISA slots if an optional LPC/ISA bridge chip is used.

Features of the SiS730S include

- Support for AMD Athlon/Duron processors with 200MHz system bus
- Support for PC133 SDRAM
- Meet PC99 requirements
- PCI 2.2 compliant
- Four PCI masters
- Support for Ultra DMA100
- Integrated AGP 2x 2D/3D Video/Graphics Accelerator
- Support for digital flat panel
- Hardware DVD decoding
- Built-in secondary CRT controller for independent secondary CRT, LCD, or TV digital output
- LPC interface

- Advanced PCI H/W Audio (Sound Blaster 16 and DirectSound 3D compliant) and Modem
- Meets ACPI 1.0, APM 1.2 requirements
- PCI Bus Power Management Interface Spec. 1.0
- Integrated keyboard/mouse controller
- Dual USB controller with six USB ports
- Integrated 10/100Mb/sec Ethernet controller

Acer Labs Chipsets for AMD Athlon/Duron Systems

Acer Labs is a relative newcomer to the Athlon/Duron chipset business. Its Athlon/Duron chipset is described in detail in the following section.

ALiMagik1

The Acer Labs ALiMagik1 is a two-chip chipset that uses the M1647 Super North Bridge and the M1535D+ South Bridge (which is also used by its Pentium III/Celeron chipsets). The M1647 Super North Bridge is a 528-pin BGA chip.

The M1647 Super North Bridge supports SDRAM as well as DDR SDRAM at speeds of 200MHz or 266MHz. It supports up to 3GB of RAM but does not support ECC. Memory timing is x-1-1-1-1-1-1-1 in back-to-back SDRAM reads. Because the M1647 supports both conventional and DDR SDRAM, it enables system manufacturers to use the same chipset for both memory types.

The M1647 supports AGP 4x video, PCI 2.2, up to six PCI masters beyond the North Bridge and PCI bridge, ACPI and Legacy green power management, as well as PCI Mobile CLKRUN# and AGP Mobile BUSY#/STOP#.

When combined with an M1535+ South Bridge chip, the chipset is called the MobileMagiK1 and can be used on Athlon- or Duron-based portable systems.

Super I/O Chips

The third major chip seen on many PC motherboards is called the Super I/O chip. This is a chip that normally integrates devices formerly found on separate expansion cards in older systems.

Most Super I/O chips contain, at a minimum, the following components:

- Floppy controller
- Dual serial port controllers
- Parallel port controller

The floppy controllers on most Super I/O chips handle two drives, but some of them can handle only one. Older systems often required a separate floppy controller card.

The dual serial port is another item that was formerly on one or more cards. Most of the better Super I/O chips implement a buffered serial port design known as a universal asynchronous receiver transmitter (UART), one for each port. Most mimic the standalone NS16550A high-speed UART, which was created by National Semiconductor. By putting the functions of two of these chips into the Super I/O chip, we essentially have these ports built-in to the motherboard.

Virtually all Super I/O chips also include a high-speed multimode parallel port. The better ones allow three modes: standard (bidirectional), Enhanced Parallel Port (EPP), and the Enhanced Capabilities Port (ECP) modes. The ECP mode is the fastest and most powerful, but selecting it also means your port will use an ISA bus 8-bit DMA channel—usually DMA channel 3. As long as you account for this and don't set anything else to that channel (such as a sound card and so on), the EPC mode parallel port should work fine. Some of the newer printers and scanners that connect to the system via the parallel port use ECP mode, which was invented by Hewlett-Packard.

The Super I/O chip can contain other components, as well. For example, the Intel VC820 ATX motherboard uses an SMC (Standard Microsystems Corp.) LPC47M102 Super I/O chip. This chip incorporates the following functions:

- Floppy drive interface
- Two high-speed serial ports
- One ECP/EPP multimode parallel port
- 8042-style keyboard and mouse controller

Only the keyboard and mouse controller are surprising here; all the other components are in most Super I/O chips. The integrated keyboard and mouse controller saves the need to have this chip as a separate part on the board.

One thing I've noticed over the years is that the role of the Super I/O chip has decreased more and more in the newer motherboards. This is primarily due to Intel and other chipset manufacturers moving Super I/O functions, such as IDE, directly into the chipset South Bridge or ICH component, where these devices can attach to the PCI bus (North/South Bridge architecture) or to the high-speed hub interface (hub architecture) rather than the ISA bus. One of the shortcomings of the Super I/O chip is that originally it was interfaced to the system via the ISA bus and shared all the speed and performance limitations of that 8MHz bus. Moving the IDE over to the PCI bus allowed higher-speed IDE drives to be developed that could transfer at the faster 33MHz PCI bus speed.

Newer Super I/O chips interface to the system via the LPC bus, an interface designed by Intel to offer a low-speed connection (up to about 6.67MB/sec) using only 13 signals. Although technically slower than ISA, it is much more efficient, and nothing in the Super I/O chip needs any greater bandwidth anyway.

As the chipset manufacturers combine more and more functions into the main chipset, and as USB-based peripherals replace standard serial, parallel, and floppy controller–based devices, we will probably see the Super I/O chip continue to fade away in motherboard designs. More and more current chipsets are combining the South Bridge and Super I/O chips into a single component to save space and reduce parts count on the motherboard. Several of the SiS chipsets even integrate all three chips (North Bridge, South Bridge, and Super I/O) into a single chip.

Motherboard CMOS RAM Addresses

In the original AT system, a Motorola 146818 chip was used as the RTC and Complementary Metal-Oxide Semiconductor (CMOS) RAM chip. This is a special chip that had a simple digital clock, which used 10 bytes of RAM and an additional 54 more bytes of leftover RAM in which you could store anything you wanted. The designers of the IBM AT used these extra 54 bytes to store the system configuration.

Modern PC systems don't use the Motorola chip; instead, they incorporate the functions of this chip into the motherboard chipset (South Bridge) or Super I/O chip, or they use a special battery and NVRAM module from companies such as Dallas or Benchmarq.

For more detail on the CMOS RAM addresses, see the section "Motherboard CMOS RAM Addresses" in Chapter 5, "BIOS."

Motherboard Interface Connectors

There are a variety of connectors on a modern motherboard. Figure 4.42 shows the locations of these connectors on a typical motherboard (using the Intel SE440BX model as the example). Several of these connectors, such as power supply connectors, serial and parallel ports, and keyboard/mouse connectors, are covered in other chapters. Tables 4.14–4.18 contain the pinouts of most of the other different interface and I/O connectors you will find.

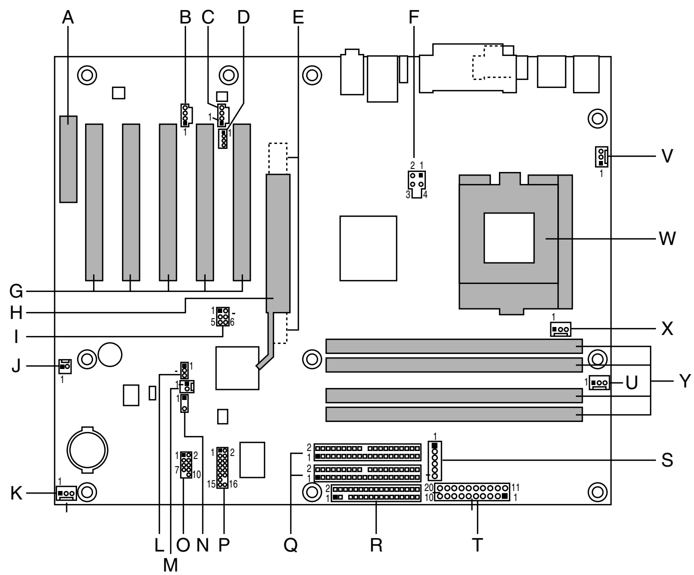
▶▶ See "AT Power Supply Connectors," p. 1117.

▶▶ See "Serial Ports," p. 924, and "Parallel Ports," p. 933.

▶▶ See "Keyboard/Mouse Interface Connectors," p. 969.

▶▶ See "Universal Serial Bus," p. 940.

▶▶ See "ATA I/O Connector," p. 486.



A Communications and Network Riser (CNR)
B Optional auxiliary line in, ATAPI style (for audio)
C Optional ATAPI CD-ROM (for audio)
D Optional CD-ROM legacy style, 2mm (for audio)
E Optional AGP Pro slot extension
F ATX 12V power connector
G 32-bit PCI expansion slots

Caution

Do not place a jumper on this connector; serious board damage will result if the 12v is shorted to ground.

Note that some boards have a board-mounted piezo speaker. It is enabled by placing a jumper over pins 3 and 4, which routes the speaker output to the board-mounted speaker. Removing the jumper enables a conventional speaker to be plugged in.

Some other connectors that you might find on some newer motherboards are listed in Tables 4.19–4.24.

System Bus Types, Functions, and Features

The heart of any motherboard are the various buses that carry signals between the components. A *bus* is a common pathway across which data can travel within a computer. This pathway is used for communication and can be established between two or more computer elements.

The PC has a hierarchy of different buses. Most modern PCs have at least three buses; some have four or more. They are hierarchical because each slower bus is connected to the faster one above it. Each device in the system is connected to one of the buses, and some devices (primarily the chipset) act as bridges between the various buses.

The main buses in a modern system are as follows:

- *Processor bus*. Also called the front-side bus (FSB), this is the highest-speed bus in the system and is at the core of the chipset and motherboard. This bus is used primarily by the processor to pass information to and from cache or main memory and the North Bridge of the chipset. The processor bus in a modern system runs at 66MHz, 100MHz, 133MHz, or 200MHz and is normally 64 bits (8 bytes) wide.

- *AGP bus*. This is a high-speed 32-bit bus specifically for a video card. It runs at 66MHz (AGP 1x), 133MHz (AGP 2x), 266MHz (AGP 4x), or 533MHz (AGP 8x), which allows for a bandwidth of up to 2,133MB/second. It is connected to the North Bridge or Memory Controller Hub of the chipset and is manifested as a single AGP slot in systems that support it.
- *PCI bus*. This is normally a 33MHz 32-bit bus found in virtually all newer 486 systems and Pentium and higher processor systems. Some newer systems include an optional 66MHz 64-bit version—mostly workstations or server-class systems. This bus is generated by either the chipset North Bridge in North/South Bridge chipsets or the I/O Controller Hub in chipsets using hub architecture. This bus is manifested in the system as a collection of 32-bit slots, normally white in color and numbering from four to six on most motherboards. High-speed peripherals, such as SCSI adapters, network cards, video cards, and more, can be plugged into PCI bus slots.
- *ISA bus*. This is an 8MHz, 16-bit bus that still remains in a few systems today after first appearing in the original PC in 8-bit, 5MHz form and in the 1984 IBM AT in full 16-bit 8MHz form. It is a very slow-speed bus but was ideal for certain slow-speed or older peripherals. Most newer PC motherboard designs no longer include this bus. It has been used in the past for plug-in modems, sound cards, and various other low-speed peripherals. The ISA bus is generated by the South Bridge part of the motherboard chipset, which acts as the ISA bus controller and the interface between the ISA bus and the faster PCI bus above it. The Super I/O chip usually was connected to the ISA bus on systems that included ISA slots.

Some newer motherboards feature a special connector called an Audio Modem Riser (AMR) or a Communications and Networking Riser (CNR). These are dedicated connectors for cards that are specific to the motherboard design to offer communications and networking options. They are *not* designed to be general-purpose bus interfaces, and few cards for these connectors will be offered on the open market. Usually, they're offered only as an option with a given motherboard. They are designed such that a motherboard manufacturer can easily offer its boards in versions with and without communications options, without having to reserve space on the board for optional chips. Normal network and modem options offered publicly will still be PCI based for the most part because the AMR/CNR connection is somewhat motherboard specific.

Several hidden buses exist on modern motherboards, buses that don't manifest themselves in visible slots or connectors. I'm talking about buses designed to interface chipset components, such as the Hub Interface and the LPC bus. The Hub Interface is a quad-clocked (4x) 66MHz 8-bit bus that carries data between the MCH and ICH in hub architecture chipsets. It operates at a bandwidth of 266MB/sec and was designed as a chipset component connection that is faster than PCI and yet uses fewer signals for a lower-cost design.

In a similar fashion, the LPC bus is a 4-bit bus that has a maximum bandwidth of 6.67MB/sec; it was designed as an economical onboard replacement for the ISA bus. In systems that use LPC, it typically is used to connect Super I/O chip or motherboard ROM BIOS components to the main chipset. LPC is nearly as fast as ISA and yet uses far fewer pins and enables ISA to be eliminated from the board entirely.

The system chipset is the conductor that controls the orchestra of system components, enabling each to have its turn on its respective buses. Table 4.26 shows the widths, speeds, data cycles, and overall bandwidth of virtually all PC buses.

Table 4.26 Bandwidth (in MB/sec) and Detail Comparison of Most PC Buses and Interfaces

Bus Type	Bus Width (bits)	Bus Speed (MHz)	Data Cycles per Clock	Bandwidth (MB/sec)
8-bit ISA (PC/XT)	8	4.77	1/2	2.39

Table 4.26 Continued

Bus Type	Bus Width (bits)	Bus Speed (MHz)	Data Cycles per Clock	Bandwidth (MB/sec)
66MHz 64-bit CPU FSB	64	66	1	533
100MHz 64-bit CPU FSB	64	100	1	800
133MHz 64-bit CPU FSB	64	133	1	1,066
200MHz 64-bit CPU FSB	64	100	2	1,600
266MHz 64-bit CPU FSB	64	133	2	2,133
400MHz 64-bit CPU FSB	64	100	4	3,200

Note: ISA, EISA, VL-Bus, and MCA are no longer used in current motherboard designs.
MB/sec = Megabytes per second.
ISA = Industry Standard Architecture, also known as the PC/XT (8-bit) or AT-Bus (16-bit).
LPC = Low pin count bus.
DD Floppy = Double-Density (360/720KB) Floppy.
HD Floppy = High-Density (1.2/1.44MB) Floppy.
ED Floppy = Extra-high Density (2.88MB) Floppy.
EISA = Extended Industry Standard Architecture (32-bit ISA).
VL-Bus = VESA (Video Electronics Standards Association) Local Bus (ISA extension).
MCA = Microchannel architecture (IBM PS/2 systems).
PC-Card = 16-bit PCMCIA (Personal Computer Memory Card International Association) interface.
CardBus = 32-bit PC-Card.
Hub Interface = Intel 8xx chipset bus.
PCI = Peripheral component interconnect.
AGP = Accelerated graphics port.
RS-232 = Standard serial port, 115.2Kbps.
RS-232 HS = High-speed serial port, 230.4Kbps.
IEEE-1284 Parallel = Standard bidirectional parallel port.
IEEE-1284 EPP/ECP = Enhanced parallel port/extended capabilities port.
USB = Universal serial bus.
IEEE-1394 = FireWire, also called i.Link.
ATA PIO = AT Attachment (also known as IDE) programmed I/O.
ATA-UDMA = AT Attachment Ultra DMA.
SCSI = Small computer system interface.
FPM = Fast page mode, based on X-3-3-3 (1/3 max) burst mode timing on a 66MHz bus.
EDO = Extended data out, based on X-2-2-2 (1/2 max) burst mode timing on a 66MHz bus.
SDRAM = Synchronous dynamic RAM.
RDRAM = Rambus dynamic RAM.
RDRAM Dual = Dual-channel RDRAM (operating simultaneously).
DDR-SDRAM = Double-data rate SDRAM.
CPU FSB = Processor front-side bus.

Note that many of the buses use multiple data cycles (transfers) per clock cycle to achieve greater performance. This means the data transfer rate is higher than it would seem for a given clock rate. This allows for an easy way to take an existing bus and make it go faster in a backward-compatible way.

The following sections discuss the processor and other subset buses in the system and the main I/O buses mentioned in the previous table.

The Processor Bus (Front-Side Bus)

The processor bus (also called the Front-side bus or FSB) is the communication pathway between the CPU and motherboard chipset, more specifically the North Bridge or Memory Controller Hub. This bus runs at the full motherboard speed—normally between 66MHz and 400MHz in modern systems, depending on the particular board and chipset design. This same bus also transfers data between the CPU and an external (L2) memory cache on Socket-7 (Pentium class) systems. Figure 4.44 shows how this bus fits into a typical Socket-7 PC system.

Figure 4.44 also shows where and how the other main buses, such as the PCI and ISA buses, fit into the system. As you can see, there is clearly a three-tier architecture with the fastest CPU bus on top, the PCI bus next, and the ISA bus at the bottom. Various components in the system are connected to one of these three main buses.

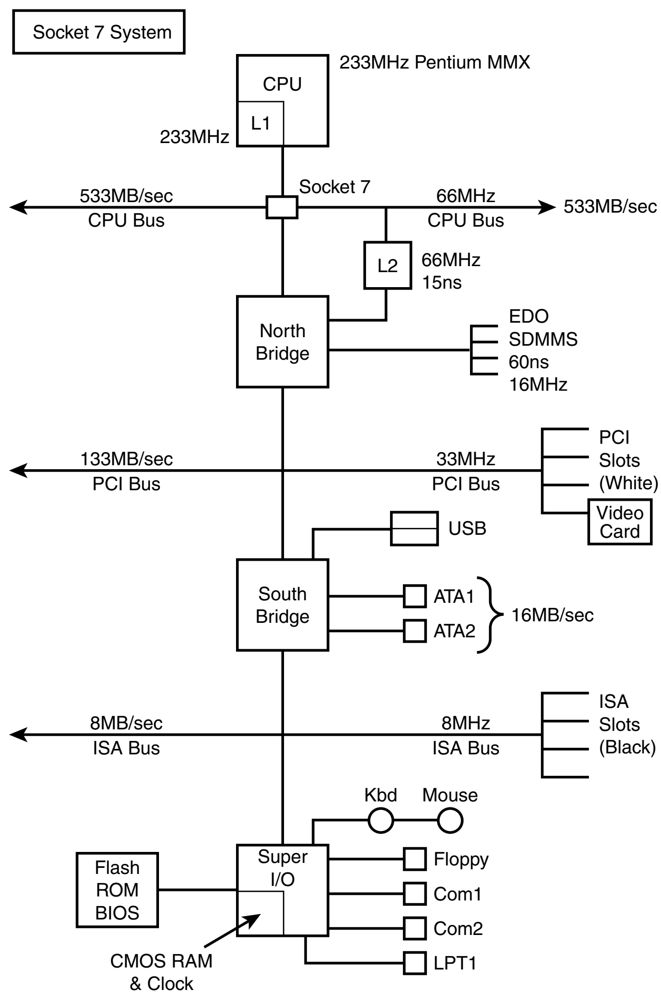

Figure 4.44 Typical Socket-7 (Pentium class) system architecture.

Socket-7 systems have an external (L2) cache for the CPU; the L2 cache is mounted on the motherboard and connected to the main processor bus that runs at the motherboard speed (normally between 66MHz and 100MHz). Thus, as the Socket-7 processors became available in faster and faster versions (through increasing the clock multiplier in the chip), the L2 cache unfortunately remained stuck on the motherboard running at the relatively slow (by comparison) motherboard speed. For example, the fastest Intel Socket-7 systems ran the CPU at 233MHz, which was 3.5X the CPU bus speed of 66MHz. Therefore, the L2 cache ran at only 66MHz. The fastest Socket-7 systems used the AMD K6-2 550 processor, which ran at 550MHz—5.5X a CPU bus speed of 100MHz. In those systems, the L2 cache ran at only 100MHz.

The problem of the slow L2 cache was first solved in the P6 class processors, such as the Pentium Pro, Pentium II, Celeron, Pentium III, and AMD Athlon and Duron. These processors used either Socket 8, Slot 1, Slot 2, Slot A, Socket A, or Socket 370. They moved the L2 cache off the motherboard and directly onto the CPU and connected it to the CPU via an on-chip back-side bus. Because the L2 cache bus was called the back-side bus, some in the industry began calling the main CPU bus the front-side bus. I still usually refer to it simply as the CPU bus.

By incorporating the L2 cache into the CPU, it can run at speeds up to the same speed as the processor itself. Most processors now incorporate the L2 cache directly on the CPU die, so the L2 cache runs at the same speed as the rest of the CPU. Others (mostly older versions) used separate die for the cache integrated into the CPU package, which ran the L2 cache at some lower multiple (1/2, 2/5, or 1/3) of the main CPU. Even if the L2 ran at 1/2 or 1/3 of the processor speed, it still was significantly faster than the motherboard-bound cache on the Socket-7 systems.

Figure 4.45 shows a typical Slot-1 type system, in which the L2 cache is built into the CPU but running at only half the processor speed. This would also be the same for systems using Slot-A. The CPU bus speed increased from 66MHz (used primarily in Socket-7 systems) to 100MHz, enabling a bandwidth of 800MB/sec. Note that most of these systems included AGP support. Basic AGP was 66MHz (twice the speed of PCI), but most of these systems incorporated AGP 2x, which operated at twice the speed of standard AGP, enabling a bandwidth of 533 MB/sec. These systems also typically used PC-100 SDRAM DIMMs, which have a bandwidth of 800MB/sec, matching the processor bus bandwidth for the best performance.

Slot-1 was dropped in favor of Socket 370 for the Pentium III and Celeron systems. This was mainly because these newer processors incorporated the L2 cache directly into the CPU die (running at the full core speed of the processor), and an expensive cartridge with multiple chips was no longer necessary. At the same time, processor bus speeds increased to 133MHz, which enabled a throughput of 1,066MB/sec. Figure 4.46 shows a typical Socket-370 system design. AGP speed was also increased to AGP 4x, with a bandwidth of 1,066MB/sec.

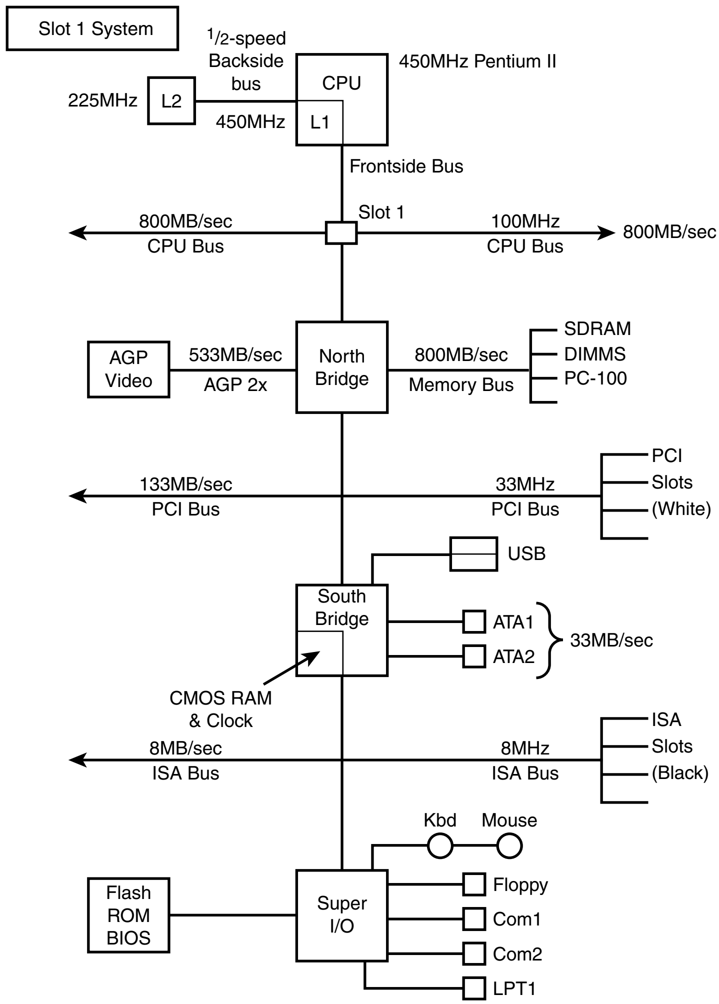

Figure 4.45 Typical Slot-1 (Pentium II class) system architecture.

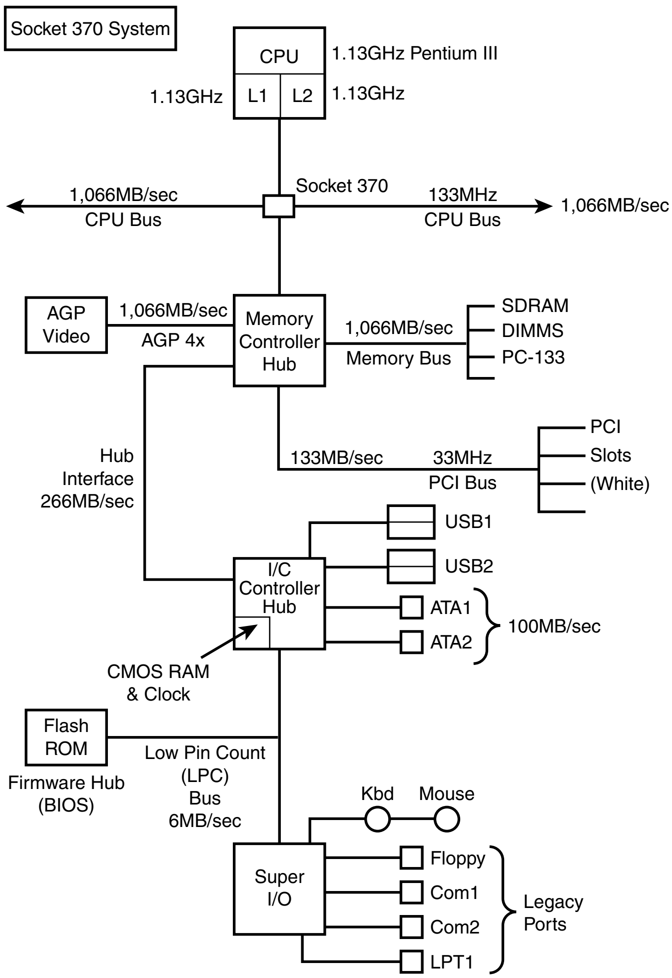

Figure 4.46 Typical Socket-370 (Pentium III/Celeron class) system architecture.

Note the use of what Intel calls "hub architecture" instead of the older North/South Bridge design. This moves the main connection between the chipset components to a separate 266MB/sec hub interface (which has twice the throughput of PCI) and enables PCI devices to use the full bandwidth of PCI without fighting for bandwidth with a South Bridge. Also note that the flash ROM BIOS chip is now referred to as a Firmware Hub and is connected to the system via the LPC bus instead of via the Super I/O chip as in older North/South Bridge designs. The ISA bus is no longer used in most of these systems, and the Super I/O is connected via the LPC bus instead of ISA. The Super I/O chip also can be easily eliminated in these designs. This is commonly referred to as a *legacy-free* system because the ports supplied by the Super I/O chip are now known as *legacy* ports. Devices that would have used legacy ports must then be connected to the system via USB instead, and such systems would normally feature two USB controllers, with up to four total ports (more can be added by attaching USB hubs).

AMD processor systems adopted a Socket-A design, which is similar to Socket-370 except it uses faster processor and memory buses and yet also retains the older North/South Bridge design. Figure 4.47 shows a typical Socket-A system design. Note the high-speed CPU bus running up to 266MHz (2,133MB/sec throughput) and the use of DDR SDRAM DIMM modules that support a matching bandwidth of 2,133MB/sec. It is always best for performance when the bandwidth of memory matches that of the processor. Finally note how most of the South Bridge components include functions otherwise found in Super I/O chips; when these functions are included the chip is called a Super South Bridge.

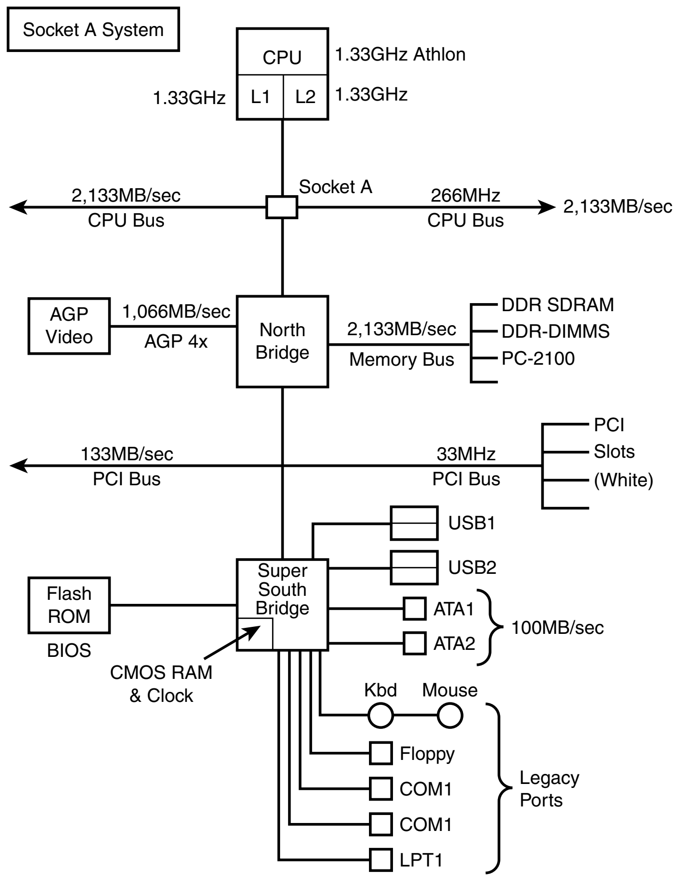

Figure 4.47 Typical Socket-A (Athlon/Duron) system architecture.

The Pentium 4 uses a Socket-423 design with hub architecture (see Figure 4.48). This design is most notable for including a 400MHz CPU bus with a bandwidth of 3,200MB/sec, currently faster than anything else on the market. Also note the use of dual-channel PC-800 RDRAM RIMMs, which have a 3,200MB/sec bandwidth, matching that of the processor bus exactly for the best performance.

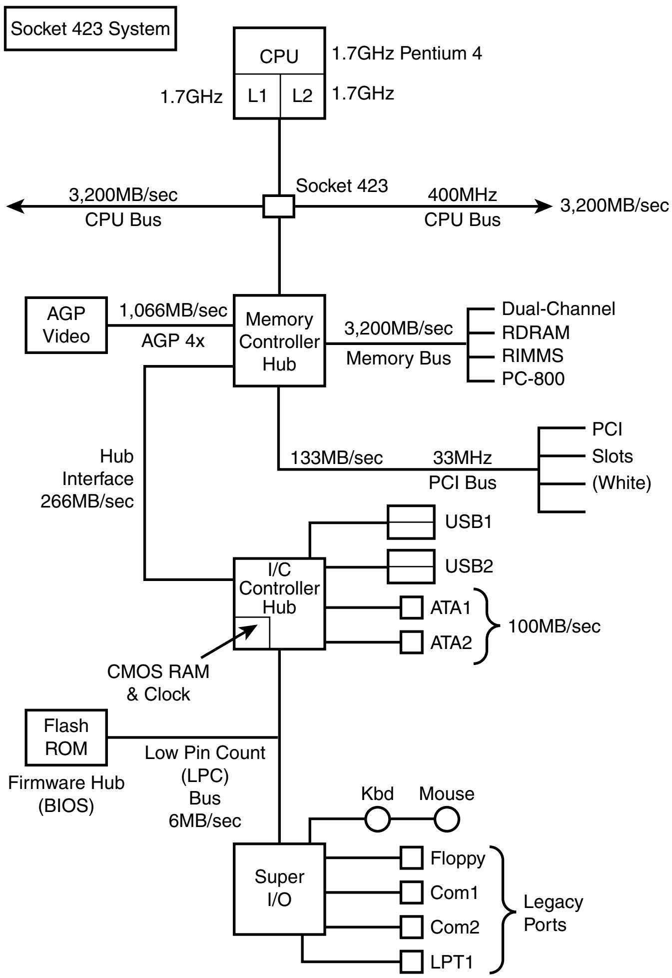

Figure 4.48 Typical Socket-423 (Pentium 4) system architecture.

Because the purpose of the processor bus is to get information to and from the CPU at the fastest possible speed, this bus typically operates at a faster rate than any other bus in your system. The bus consists of electrical circuits for data, addresses (the address bus, which is discussed in the following section), and control purposes. Most processors since the original Pentium have a 64-bit data bus, which means they transfer 64 bits (8 bytes) at a time over the CPU bus.

The processor bus operates at the same base clock rate as the CPU does externally. This can be misleading because most CPUs these days run internally at a higher clock rate than they do externally. For example, a Celeron 766 system has a processor running at 766MHz internally, but only 66MHz externally, whereas a Pentium III 1GHz runs at 1GHz internally but only 133MHz externally. In most newer systems, the actual processor speed is some multiple (2x, 2.5x, 3x, and higher) of the processor bus.

◄◄ See "Processor Speed Ratings," p. 47.

The processor bus is tied to the external processor pin connections and can transfer 1 bit of data per data line every cycle. Most modern processors transfer 64 bits (8 bytes) of data at a time.

To determine the transfer rate for the processor bus, you multiply the data width (64 bits for a Celeron/Pentium III/4 or Athlon/Duron) by the clock speed of the bus (the same as the base or unmultiplied clock speed of the CPU).

For example, if you are using a Pentium III 1.13GHz that runs at a 133MHz motherboard speed, you have a maximum instantaneous transfer rate of roughly 1,066MB/sec. You get this result by using the following formula:

133.33MHz × 8 bytes (64 bits) = 1,066MB/sec

With Socket A (Athlon) you get

266.66MHz × 8 bytes (64 bits) = 2,133MB/sec

With Socket 423 (Pentium 4) you get

400MHz × 8 bytes (64 bits) = 3,200MB/sec

This transfer rate, often called the *bandwidth* of the processor bus, represents the maximum speed at which data can move. Refer to Table 4.26 for a more complete list of various processor bus bandwidths.

The Memory Bus

The memory bus is used to transfer information between the CPU and main memory—the RAM in your system. This bus is connected to the motherboard chipset North Bridge or Memory Controller Hub chip. Depending on the type of memory your chipset (and therefore motherboard) is designed to handle, the North Bridge runs the memory bus at various speeds. The best solution is if the memory bus runs at the same speed as the processor bus. Systems that use PC133 SDRAM have a memory bandwidth of 1,066MB/sec, which is the same as the 133MHz CPU bus. In another example, Athlon and Pentium III systems running a 266MHz processor bus also run PC2100 DDR-SDRAM, which has a bandwidth of 2,133MB/sec—exactly the same as the processor bus in those systems. Also, systems running a Pentium 4 with its 400MHz processor bus also use dual-channel RDRAM memory, which runs 1,600MB/sec for each channel, or a combined bandwidth (both memory channels run simultaneously) of 3,200MB/sec, which is exactly the same as the Pentium 4 CPU bus.

Running memory at the same speed as the processor bus negates the need for having cache memory on the motherboard. That is why when the L2 cache moved into the processor, nobody added an L3 cache to the motherboard. Figure 4.40 and Figure 4.41, previously in this chapter, show how the memory bus fits into your PC.

Note

Notice that the main memory bus is always the same width as the processor bus. This defines the size of what is called a *bank* of memory, at least when dealing with anything but RDRAM. Memory banks and their widths relative to processor buses are discussed in the section "Memory Banks" in Chapter 6.

The Need for Expansion Slots

The I/O bus or expansion slots are what enables your CPU to communicate with peripheral devices. The bus and its associated expansion slots are needed because basic systems cannot possibly satisfy all the needs of all the people who buy them. The I/O bus enables you to add devices to your computer to expand its capabilities. The most basic computer components, such as sound cards and video cards, can be plugged into expansion slots; you also can plug in more specialized devices, such as network interface cards, SCSI host adapters, and others.

Note

In most modern PC systems, a variety of basic peripheral devices are built into the motherboard. Most systems today have at least dual (primary and secondary) IDE interfaces, dual USB ports, a floppy controller, two serial ports, a parallel port, keyboard, and mouse controller built directly into the motherboard. These devices are normally distributed between the motherboard chipset South Bridge and the Super I/O chip. (Super I/O chips are discussed earlier in this chapter.)

Many add even more items, such as a built-in sound card, video adapter, SCSI host adapter, or network interface, that also are built into the motherboard. Those items, however, are not built into the motherboard chipset or Super I/O chip, but are configured as additional chips installed on the board. Nevertheless, these built-in controllers and ports still use the I/O bus to communicate with the CPU. In essence, even though they are built in, they act as if there were cards plugged into the system's bus slots, including using system resources in the same manner.

Types of I/O Buses

Since the introduction of the first PC, many I/O buses have been introduced. The reason is simple: Faster I/O speeds are necessary for better system performance. This need for higher performance involves three main areas:

- Faster CPUs
- Increasing software demands
- Greater multimedia requirements

Each of these areas requires the I/O bus to be as fast as possible.

One of the primary reasons new I/O-bus structures have been slow in coming is compatibility—that old catch-22 that anchors much of the PC industry to the past. One of the hallmarks of the PC's success is its standardization. This standardization spawned thousands of third-party I/O cards, each originally built for the early bus specifications of the PC. If a new high-performance bus system was introduced, it often had to be compatible with the older bus systems so the older I/O cards would not be obsolete. Therefore, bus technologies seem to evolve rather than make quantum leaps forward.

You can identify different types of I/O buses by their architectures. The main types of I/O buses are detailed earlier in this chapter.

The main differences among buses consist primarily of the amounts of data they can transfer at one time and the speeds at which they can do it. The following sections describe the various types of PC buses.

The ISA Bus

ISA, which is an abbreviation for Industry Standard Architecture, is the bus architecture that was introduced as an 8-bit bus with the original IBM PC in 1981; it was later expanded to 16 bits with the IBM PC/AT in 1984. ISA is the basis of the modern personal computer and the primary architecture used in the vast majority of PC systems on the market today. It might seem amazing that such a presumably antiquated architecture is used in today's high-performance systems, but this is true for reasons of reliability, affordability, and compatibility, plus this old bus is still faster than many of the peripherals we connect to it!

Note

The ISA bus is vanishing from most of the latest systems, and few companies make or sell ISA cards anymore.

Two versions of the ISA bus exist, based on the number of data bits that can be transferred on the bus at a time. The older version is an 8-bit bus; the newer version is a 16-bit bus. The original 8-bit version ran at 4.77MHz in the PC and XT. The 16-bit version used in the AT ran at 6MHz and then 8MHz. Later, the industry as a whole agreed on an 8.33MHz maximum standard speed for 8/16-bit versions of the ISA bus for backward compatibility. Some systems have the capability to run the ISA bus faster than this, but some adapter cards will not function properly at higher speeds. ISA data transfers require anywhere from two to eight cycles. Therefore, the theoretical maximum data rate of the ISA bus is about 8MB/sec, as the following formula shows:

$$8.33\text{MHz} \times 2 \text{ bytes (16 bits)} \div 2 \text{ cycles per transfer} = 8.33\text{MB/sec}$$

The bandwidth of the 8-bit bus would be half this figure (4.17MB/sec). Remember, however, that these figures are theoretical maximums; because of I/O bus protocols, the effective bandwidth is much lower—typically by almost half. Even so, at about 8MB/sec, the ISA bus is still faster than many of the peripherals connected to it, such as serial ports, parallel ports, floppy controllers, keyboard controllers, and so on.

The 8-Bit ISA Bus

This bus architecture is used in the original IBM PC computers and was retained for a number of years in later systems. Although virtually nonexistent in new systems today, this architecture still exists in hundreds of thousands of PC systems in the field.

Physically, the 8-bit ISA expansion slot resembles the tongue-and-groove system furniture makers once used to hold two pieces of wood together. It is specifically called a *card/edge connector*. An adapter card with 62 contacts on its bottom edge plugs into a slot on the motherboard that has 62 matching contacts. Electronically, this slot provides 8 data lines and 20 addressing lines, enabling the slot to handle 1MB of memory.

Figure 4.49 describes the pinouts for the 8-bit ISA bus; Figure 4.50 shows how these pins are oriented in the expansion slot.

Although the design of the bus is simple, IBM waited until 1987 to publish full specifications for the timings of the data and address lines, so in the early days of PC compatibles, manufacturers had to do their best to figure out how to make adapter boards. This problem was solved, however, as PC-compatible personal computers became more widely accepted as the industry standard and manufacturers had more time and incentive to build adapter boards that worked correctly with the bus.

The dimensions of 8-bit ISA adapter cards are as follows:

4.2 inches (106.68mm) high

13.13 inches (333.5mm) long

0.5 inch (12.7mm) wide

The 16-Bit ISA Bus

IBM threw a bombshell on the PC world when it introduced the AT with the 286 processor in 1984. This processor had a 16-bit data bus, which meant communications between the processor and the motherboard as well as memory would now be 16 bits wide instead of only 8. Although this processor could have been installed on a motherboard with only an 8-bit I/O bus, that would have meant a huge sacrifice in the performance of any adapter cards or other devices installed on the bus.

Figure 4.49 Pinouts for the 8-bit ISA bus.

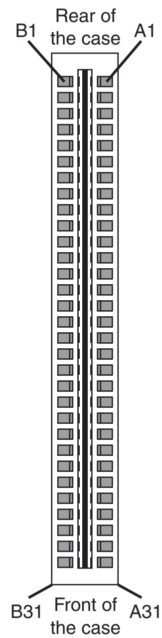

Figure 4.50 The 8-bit ISA bus connector.

Rather than create a new I/O bus, at that time IBM instead came up with a system that could support both 8- and 16-bit cards by retaining the same basic 8-bit connector layout but adding an optional 16-bit extension connector. This first debuted on the PC/AT in August 1984, which is why we also refer to the ISA bus as the *AT-bus*.

The extension connector in each 16-bit expansion slot adds 36 connector pins (for a total of 96 signals) to carry the extra signals necessary to implement the wider data path. In addition, two of the pins in the 8-bit portion of the connector were changed. These two minor changes did not alter the function of 8-bit cards.

Figure 4.51 describes the pinouts for the full 16-bit ISA expansion slot, and Figure 4.52 shows how the additional pins are oriented in the expansion slot.

Because of physical interference with some ancient 8-bit card designs, IBM left 16-bit extension connectors off two of the slots in the AT. This was not a problem in newer systems, so any system with ISA slots would have all of them as full 16-bit versions.

The dimensions of a typical AT expansion board are as follows:

4.8 inches (121.92mm) high

13.13 inches (333.5mm) long

0.5 inch (12.7mm) wide

Figure 4.51 Pinouts for the 16-bit ISA bus.

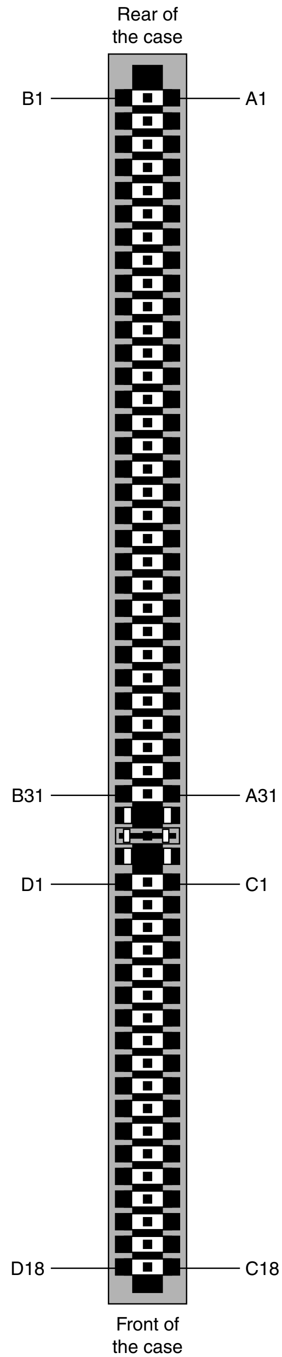

Figure 4.52 The ISA 16-bit bus connector.

Two heights actually are available for cards commonly used in AT systems: 4.8 inches and 4.2 inches (the height of older PC-XT cards). The shorter cards became an issue when IBM introduced the XT Model 286. Because this model has an AT motherboard in an XT case, it needs AT-type boards with the 4.2-inch maximum height. Most board makers trimmed the height of their boards; most manufacturers who still make ISA cards now make only 4.2-inch tall (or less) boards so they will work in systems with either profile.

32-Bit Buses

After 32-bit CPUs became available, it was some time before 32-bit bus standards became available. Before MCA and EISA specs were released, some vendors began creating their own proprietary 32-bit buses, which were extensions of the ISA bus. Although the proprietary buses were few and far between, they do still exist.

The expanded portions of the bus typically are used for proprietary memory expansion or video cards. Because the systems are proprietary (meaning that they are nonstandard), pinouts and specifications are not available.

The Micro Channel Bus

The introduction of 32-bit chips meant that the ISA bus could not handle the power of another new generation of CPUs. The 386DX chips could transfer 32 bits of data at a time, but the ISA bus can handle a maximum of only 16 bits. Rather than extend the ISA bus again, IBM decided to build a new bus; the result was the MCA bus. *MCA* (an abbreviation for microchannel architecture) is completely different from the ISA bus and was technically superior in every way.

IBM wanted not only to replace the old ISA standard, but also to require vendors to license certain parts of the technology. Many owed for licenses on the ISA-bus technology that IBM also created, but because IBM had not been aggressive in its licensing of ISA, many got away without any license. Problems with licensing and control led to the development of the competing EISA bus (see the next section on the EISA bus) and hindered acceptance of the MCA bus.

MCA systems produced a new level of ease of use; they were plug-and-play before the official Plug and Play specification even existed. An MCA system had no jumpers and switches—neither on the motherboard nor on any expansion adapter. Instead you used a special Reference disk, which went with the particular system, and Option disks, which went with each of the cards installed in the system. After a card was installed, you loaded the Option disks files onto the Reference disk; after that, you didn't need the Option disks anymore. The Reference disk contained the special BIOS and system setup program necessary for an MCA system, and the system couldn't be configured without it. To support older PS/2 systems, IBM maintains a library of all its Reference and Options disks at `ftp://ftp.pc.ibm.com/pub/pccbbs`. Check this site if you are supporting any old MCA-based systems and need any of these files.

For more information on the MCA bus, see the previous editions of this book on the included CD-ROM.

The EISA Bus

EISA is an abbreviation for Extended Industry Standard Architecture. This standard was announced in September 1988 as a response to IBM's introduction of the MCA bus—more specifically, to the way that IBM wanted to handle licensing of the MCA bus. Vendors did not feel obligated to pay retroactive royalties on the ISA bus, so they turned their backs on IBM and created their own buses.

The EISA standard was developed primarily by Compaq and was intended to be its way of taking over future development of the PC bus from IBM. Compaq knew that nobody would clone its bus if it was the only company that had it, so it essentially gave the design away to other leading manufacturers. Compaq formed the EISA committee, a nonprofit organization designed specifically to control development of the EISA bus. Very few EISA adapters were ever developed. Those that were developed centered mainly around disk array controllers and server-type network cards.

The EISA bus was essentially a 32-bit version of ISA. Unlike the MCA bus from IBM, you could still use older 8-bit or 16-bit ISA cards in 32-bit EISA slots, providing for full backward compatibility. As with MCA, EISA also allowed for automatic configuration of EISA cards via software.

The EISA bus added 90 new connections (55 new signals plus grounds) without increasing the physical connector size of the 16-bit ISA bus. At first glance, the 32-bit EISA slot looks a lot like the 16-bit ISA slot. The EISA adapter, however, has two rows of stacked contacts. The first row is the same type used in 16-bit ISA cards; the other, thinner row extends from the 16-bit connectors. Therefore, ISA cards can still be used in EISA bus slots. Although this compatibility was not enough to ensure the popularity of EISA buses, it is a feature that was carried over into the VL-Bus standard that followed. The physical specifications of an EISA card are as follows:

- 5 inches (127mm) high
- 13.13 inches (333.5mm) long
- 0.5 inches (12.7mm) wide

The EISA bus can handle up to 32 bits of data at an 8.33MHz cycle rate. Most data transfers require a minimum of two cycles, although faster cycle rates are possible if an adapter card provides tight timing specifications. The maximum bandwidth on the bus is 33MB/sec, as the following formula shows:

- 8.33MHz × 4 bytes (32 bits) = 33MB/sec

Figure 4.53 describes the pinouts for the EISA bus. Figure 4.54 shows the locations of the pins; note how some pins are offset to allow the EISA slot to accept ISA cards. Figure 4.55 shows the card connector for the EISA expansion slot.

Local Buses

The I/O buses discussed so far (ISA, MCA, and EISA) have one thing in common: relatively slow speed. The next three bus types that are discussed in the following few sections all use the *local bus* concept explained in this section to address the speed issue. The three main local buses found in PC systems are

- VL-Bus (VESA local bus)
- PCI
- AGP

The speed limitation of ISA, MCA, and EISA is a carryover from the days of the original PC, when the I/O bus operated at the same speed as the processor bus. As the speed of the processor bus increased, the I/O bus realized only nominal speed improvements, primarily from an increase in the bandwidth of the bus. The I/O bus had to remain at a slower speed because the huge installed base of adapter cards could operate only at slower speeds.

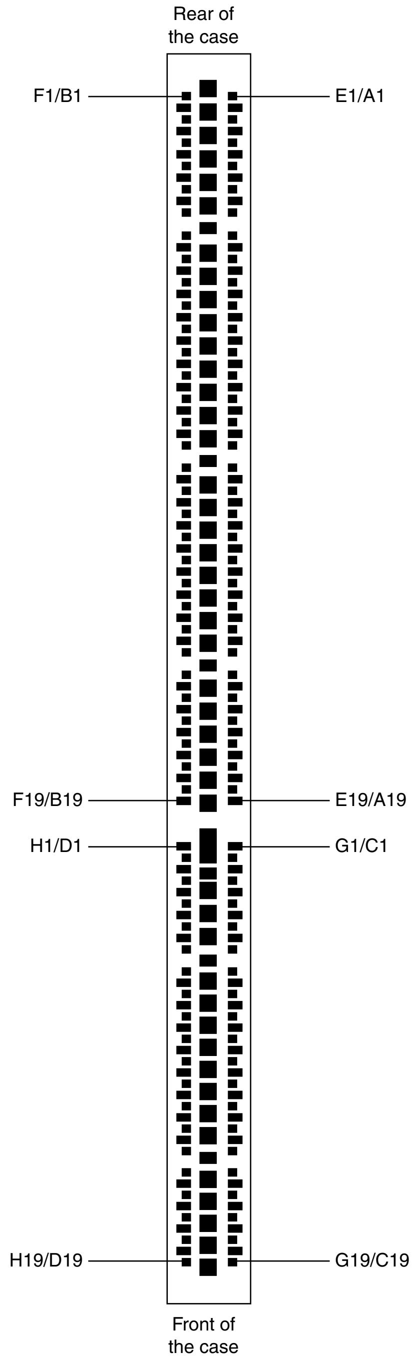

Figure 4.55 The EISA bus connector.

Figure 4.56 shows a conceptual block diagram of the buses in a computer system.

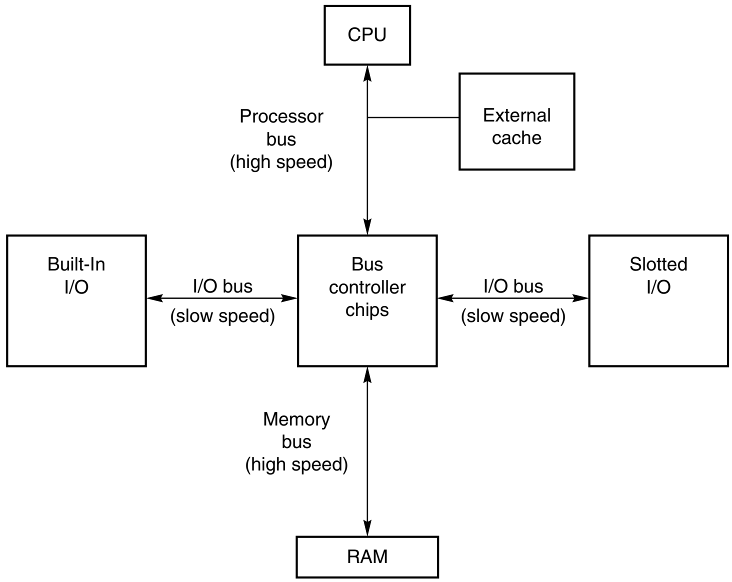

Figure 4.56 Bus layout in a traditional PC.

The thought of a computer system running more slowly than it could is very bothersome to some computer users. Even so, the slow speed of the I/O bus is nothing more than a nuisance in most cases. You don't need blazing speed to communicate with a keyboard or mouse—you gain nothing in performance. The real problem occurs in subsystems in which you need the speed, such as video and disk controllers.

The speed problem became acute when graphical user interfaces (such as Windows) became prevalent. These systems require the processing of so much video data that the I/O bus became a literal bottleneck for the entire computer system. In other words, it did little good to have a processor that was capable of 66MHz–450MHz or faster if you could put data through the I/O bus at a rate of only 8MHz.

An obvious solution to this problem is to move some of the slotted I/O to an area where it could access the faster speeds of the processor bus—much the same way as the external cache. Figure 4.57 shows this arrangement.

This arrangement became known as *local bus* because external devices (adapter cards) now could access the part of the bus that was local to the CPU—the processor bus. Physically, the slots provided to tap this new configuration would need to be different from existing bus slots to prevent adapter cards designed for slower buses from being plugged into the higher bus speeds, which this design made accessible.

It is interesting to note that the very first 8-bit and 16-bit ISA buses were a form of local bus architecture. These systems had the processor bus as the main bus, and everything ran at full processor speeds. When ISA systems ran faster than 8MHz, the main ISA bus had to be decoupled from the processor bus because expansion cards, memory, and so on could not keep up. In 1992, an extension to the ISA bus called the VESA local bus (VL-Bus) started showing up on PC systems, indicating a return to local bus architecture. Since then, the peripheral component interconnect local bus has supplanted VL-Bus, and the AGP bus has been introduced to complement PCI.

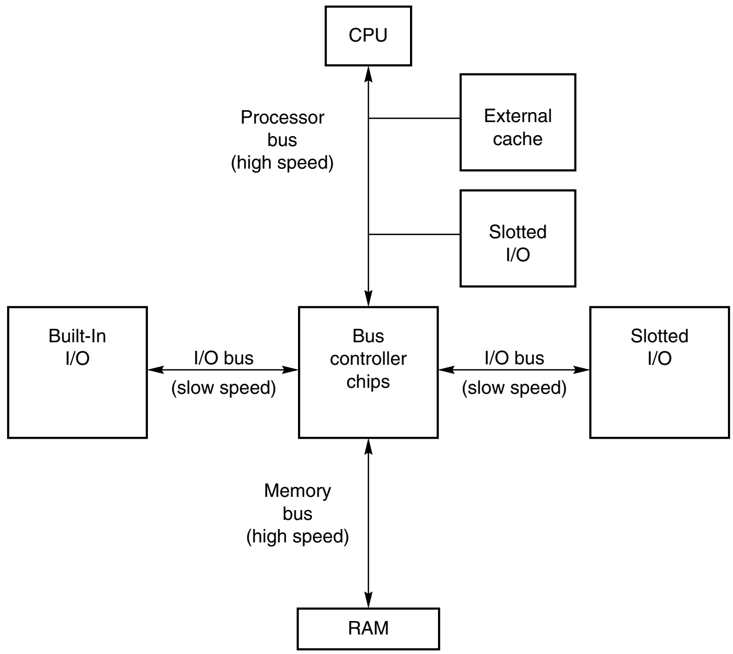

Figure 4.57 How a local bus works.

Note

A system does not have to have a local bus expansion slot to incorporate local bus technology; instead, the local bus device can be built directly into the motherboard. (In such a case, the local bus–slotted I/O shown in Figure 4.53 would in fact be built-in I/O.) This built-in approach to local bus is the way the first local bus systems were designed.

Local bus solutions do not replace earlier standards, such as ISA; they are designed into the system as a bus that is closer to the processor in the system architecture. Older buses such as ISA have been kept around for backward compatibility with slower types of adapters that don't need any faster connection to the system (such as modems). Therefore, a typical system might have AGP, PCI, and ISA slots. Older cards still are compatible with the system, but high-speed adapter cards can take advantage of the AGP and PCI local bus slots as well.

The performance of graphical user interfaces such as Windows and OS/2 have been tremendously improved by moving the video cards off the slow ISA bus and onto faster PCI and now AGP local buses.

VESA Local Bus

The Video Electronics Standards Association (VESA) local bus was the most popular local bus design from its debut in August 1992 through 1994. It was created by the VESA committee, a nonprofit organization originally founded by NEC to further develop video display and bus standards. In a similar fashion to how EISA evolved, NEC had done most of the work on the VL-Bus (as it would be called) and, after founding the nonprofit VESA committee, NEC turned over future development to VESA. At first, the local bus slot seemed primarily designed to be used for video cards. Improving video performance was a top priority at NEC to help sell its high-end displays as well as its own PC systems. By 1991, video performance had become a real bottleneck in most PC systems.

The VL-Bus can move data 32 bits at a time, enabling data to flow between the CPU and a compatible video subsystem or hard drive at the full 32-bit data width of the 486 chip. The maximum rated throughput of the VL-Bus is 133MB/sec. In other words, local bus went a long way toward removing the major bottlenecks that existed in earlier bus configurations.

Unfortunately, the VL-Bus did not seem to be a long-lived concept. The design was simple indeed—just take the pins from the 486 processor and run them out to a card connector socket. So, the VL-Bus is essentially the raw 486 processor bus. This allowed a very inexpensive design because no additional chipsets or interface chips were required. A motherboard designer could add VL-Bus slots to its 486 motherboards very easily and at a very low cost. This is why these slots appeared on virtually all 486 system designs overnight.

Problems arose with timing glitches caused by the capacitance introduced into the circuit by different cards. Because the VL-Bus ran at the same speed as the processor bus, different processor speeds meant different bus speeds, and full compatibility was difficult to achieve. Although the VL-Bus could be adapted to other processors—including the 386 or even the Pentium—it was designed for the 486 and worked best as a 486 solution only. Despite the low cost, after a new bus called PCI appeared, VL-Bus fell into disfavor very quickly. It never did catch on with Pentium systems, and there was little or no further development of the VL-Bus in the PC industry.

Physically, the VL-Bus slot was an extension of the slots used for whatever type of base system you have. If you have an ISA system, the VL-Bus is positioned as an extension of your existing 16-bit ISA slots. Figure 4.58 shows how the VL-Bus slots are oriented on a typical ISA/VL-Bus motherboard. The VESA extension has 112 contacts and uses the same physical connector as the MCA bus.

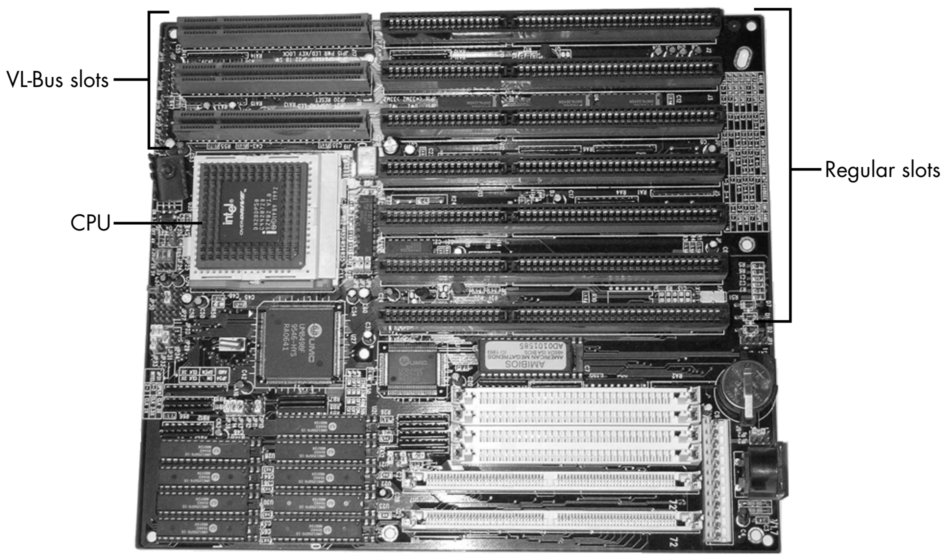

Figure 4.58 An example of a typical motherboard (albeit ancient) with VL-Bus slots.

The PCI Bus

In early 1992, Intel spearheaded the creation of another industry group. It was formed with the same goals as the VESA group in relation to the PC bus. Recognizing the need to overcome weaknesses in the ISA and EISA buses, the PCI Special Interest Group was formed.

The PCI bus specification was released in June 1992 as version 1.0 and since then has undergone several upgrades. Table 4.27 shows the various releases of PCI.

Table 4.27 PCI Specifications

PCI Specification	Released	Major Change
PCI 1.0	June 1992	Original 32/64-bit specification
PCI 2.0	April 1993	Defined connectors and expansion boards
PCI 2.1	June 1995	66MHz operation, transaction ordering, latency changes
PCI 2.2	Jan. 1999	Power management, mechanical clarifications
PCI-X	Sept. 1999	133MHz operation, addendum to 2.2
Mini-PCI	Nov. 1999	Small form factor boards, addendum to 2.2

PCI redesigned the traditional PC bus by inserting another bus between the CPU and the native I/O bus by means of bridges. Rather than tap directly into the processor bus, with its delicate electrical timing (as was done in the VL-Bus), a new set of controller chips was developed to extend the bus, as shown in Figure 4.59.

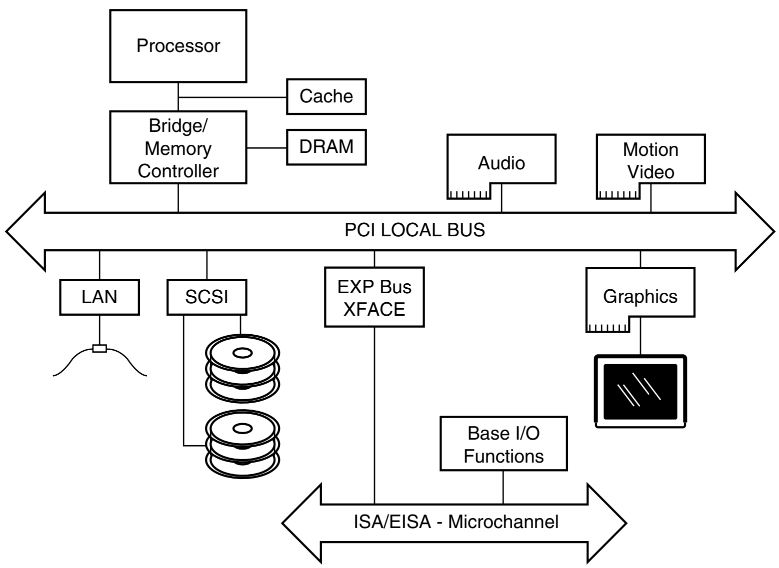

Figure 4.59 Conceptual diagram of the PCI bus.

The PCI bus often is called a *mezzanine bus* because it adds another layer to the traditional bus configuration. PCI bypasses the standard I/O bus; it uses the system bus to increase the bus clock speed and take full advantage of the CPU's data path. Systems that integrate the PCI bus became available in mid 1993 and have since become a mainstay in the PC.

Information typically is transferred across the PCI bus at 33MHz and 32 bits at a time. The bandwidth is 133MB per second, as the following formula shows:

$$33.33\text{MHz} \times 4 \text{ bytes (32 bits)} = 133\text{MB/sec}$$

Although 32-bit 33MHz PCI is the standard found in most PCs, there are now several variations on PCI as shown in Table 4.28.

Table 4.28 PCI Bus Types

PCI Bus Type	Bus Width (bits)	Bus Speed (MHz)	Data Cycles per Clock	Bandwidth (MB/sec)
PCI	32	33	1	133
PCI 66MHz	32	66	1	266
PCI 64-bit	64	33	1	266
PCI 66MHz/64-bit	64	66	1	533
PCI-X	64	133	1	1,066

Currently, the 64-bit or 66MHz and 133MHz variations are used only on server- or workstation-type boards and systems. Aiding performance is the fact that the PCI bus can operate concurrently with the processor bus; it does not supplant it. The CPU can be processing data in an external cache while the PCI bus is busy transferring information between other parts of the system—a major design benefit of the PCI bus.

A PCI adapter card uses its own unique connector. This connector can be identified within a computer system because it typically is offset from the normal ISA, MCA, or EISA connectors. See Figure 4.60 for an example. The size of a PCI card can be the same as that of the cards used in the system's normal I/O bus.

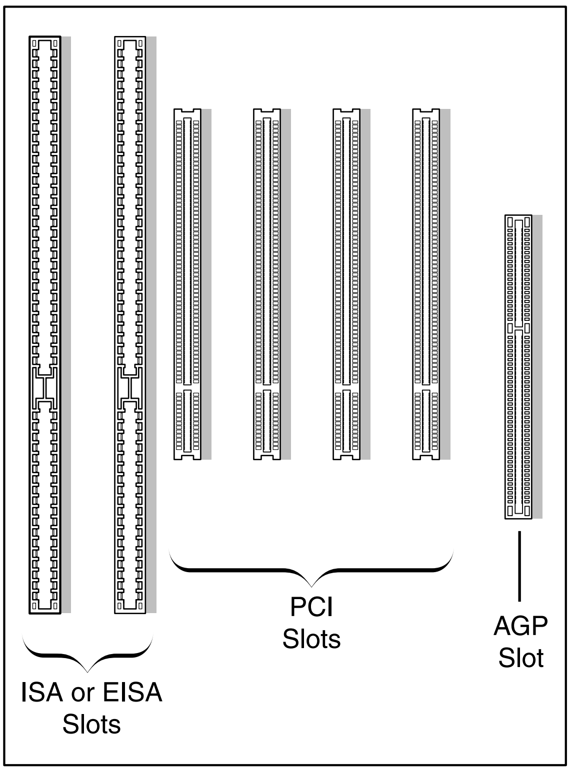

Figure 4.60 Typical configuration of 32-bit 33MHz PCI slots in relation to ISA or EISA and AGP slots.

The PCI specification identifies three board configurations, each designed for a specific type of system with specific power requirements; each specification has a 32-bit version and a longer 64-bit version. The 5v specification is for stationary computer systems, the 3.3v specification is for portable systems, and the universal specification is for motherboards and cards that work in either type of system. 64-bit versions of the 5v and universal PCI slots are found primarily on server motherboards.

Note

The pinouts for the 5v, 3.3v, and universal PCI slots can be found on the CD-ROM in the Technical Reference Section.

Figure 4.61 compares the 32-bit and 64-bit versions of the standard 5v PCI slot to a 64-bit universal PCI slot. Figure 4.62 shows how the connector on a 64-bit universal PCI card compares to the 64-bit universal PCI slot.

Notice that the universal PCI board specifications effectively combine the 5v and 3.3v specifications. For pins for which the voltage is different, the universal specification labels the pin simply V I/O. This type of pin represents a special power pin for defining and driving the PCI signaling rail.

Another important feature of PCI is the fact that it was the model for the Intel PnP specification. Therefore, PCI cards do not have jumpers and switches and are instead configured through software. True PnP systems are capable of automatically configuring the adapters, whereas non-PnP systems with ISA slots must configure the adapters through a program that is usually a part of the system CMOS configuration. Starting in late 1995, most PC-compatible systems have included a PnP BIOS that allows the automatic PnP configuration.

Accelerated Graphics Port

The AGP was created by Intel as a new bus specifically designed for high-performance graphics and video support. AGP is based on PCI, but it contains a number of additions and enhancements and is physically, electrically, and logically independent of PCI. For example, the AGP connector is similar to PCI, although it has additional signals and is positioned differently in the system. Unlike PCI, which is a true bus with multiple connectors (slots), AGP is more of a point-to-point high-performance connection designed specifically for a video card in a system because only one AGP slot is allowed for a single video card. The AGP specification 1.0 originally was released by Intel in July of 1996 and defined a 66MHz clock rate with 1x or 2x signaling using 3.3 volts. AGP version 2.0 was released in May 1998 and added 4x signaling as well as a lower 1.5v operating capability.

Caution

Some AGP 4x-compatible motherboards require you to use 1.5v AGP 4x cards only; be sure to check compatibility between the motherboard and the AGP card you want to buy to avoid problems. Some AGP 4x-compatible slots use the card retention mechanism shown in Figure 4.60. Note that AGP 1x/2x slots have a visible divider not present on the newer AGP 4x slot.

Additionally, a newer specification was introduced as AGP Pro 1.0 in August 1998 and revised in April 1999 as AGP Pro 1.1a. It defines a slightly longer slot with additional power pins at each end to drive bigger and faster AGP cards that consume more than 25 watts of power, up to a maximum of 110 watts. AGP Pro cards would likely be used for high-end graphics workstations and are not likely to be found in any normal PCs. However, AGP Pro slots are backward compatible, meaning standard AGP card will plug in, and a number of motherboard vendors are using AGP Pro slots rather than AGP 4x slots in their latest products. Because AGP Pro slots are longer, an AGP 1x/2x card can be incorrectly inserted into the slot, which could damage it, so some vendors supply a cover for the AGP Pro extension at the rear of the slot. This cover should be removed only if you want to install an AGP Pro card.

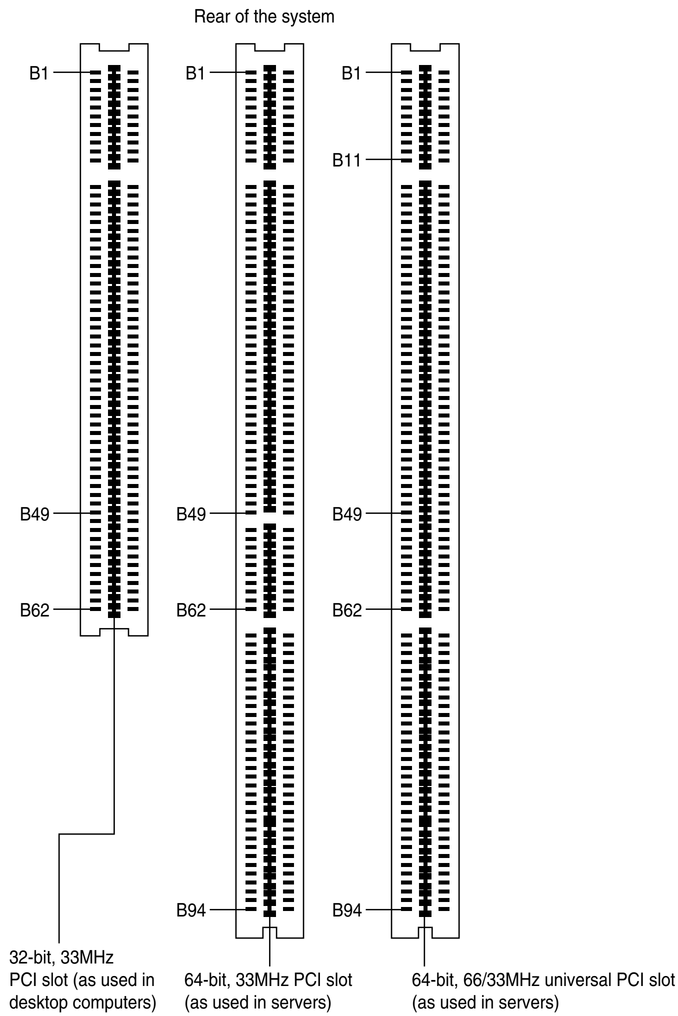

Figure 4.61 A 32-bit, 33MHz PCI slot (left) compared to a 64-bit 33MHz PCI slot (center) and a 64-bit universal PCI slot that runs at 66MHz (right).

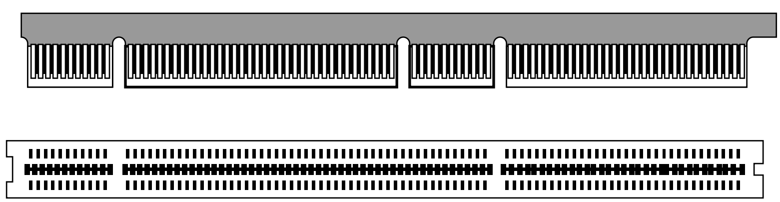

Figure 4.62 A 64-bit universal PCI card (top) compared to the 64-bit universal PCI slot (bottom).

The standard AGP 1x/2x, AGP 4x, and AGP Pro slots are compared to each other in Figure 4.63. The latest revision to the AGP specification for PCs is AGP 8x, which was announced in August 2000; it defines a faster 8x transfer mode for even greater performance than before.

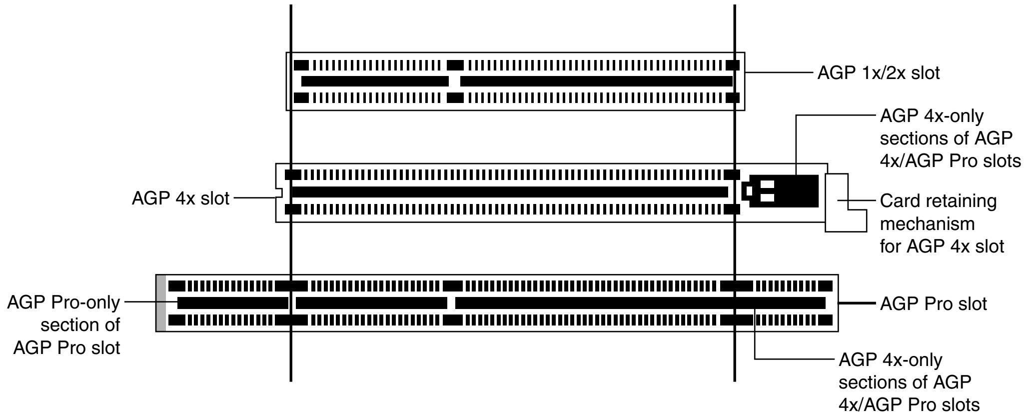

Figure 4.63 AGP standard (1x/2x), AGP 4x, and AGP Pro slots compared to each other. AGP 4x and AGP Pro can accept AGP 1x, 2x, and 4x cards.

AGP is a high-speed connection and runs at a base frequency of 66MHz (actually 66.66MHz), which is double that of standard PCI. In the basic AGP mode, called 1x, a single transfer is done every cycle. Because the AGP bus is 32 bits (4 bytes) wide, at 66 million times per second it would be capable of transferring data at a rate of about 266MB/sec! The original AGP specification also defines a 2x mode, in which two transfers are performed every cycle, resulting in 533MB/sec. Using an analogy in which every cycle is equivalent to the back-and-forth swing of a pendulum, the 1x mode is thought of as transferring information at the start of each swing. In 2x mode, an additional transfer would occur every time the pendulum completed half a swing, thereby doubling performance while technically maintaining the same clock rate, or in this case, the same number of swings per second. Although the earliest AGP cards supported only the AGP 1x mode, most vendors quickly shifted to the AGP 2x mode. The newer AGP 2.0 specification adds the capability for 4x transfers, in which data is transferred four times per cycle and equals a data transfer rate of 1,066MB/sec. Most newer AGP cards now have support for the 4x standard as a minimum. Table 4.29 shows the differences in clock rates and data transfer speeds (bandwidth) for the various AGP modes.

Table 4.29 AGP Modes Showing Clock Speeds and Bandwidth

AGP Bus Type	Bus Width (bits)	Bus Speed (MHz)	Data Cycles per Clock	Bandwidth (MB/sec)
AGP	32	66	1	266
AGP 2x	32	66	2	533
AGP 4x	32	66	4	1,066
AGP 8x	32	66	8	2,133

Because AGP is independent of PCI, using an AGP video card frees up the PCI bus for more traditional input and output, such as for IDE/ATA or SCSI controllers, USB controllers, sound cards, and so on.

Besides faster video performance, one of the main reasons Intel designed AGP was to allow the video card to have a high-speed connection directly to the system RAM, which would enable a reasonably fast and powerful video solution to be integrated at a lower cost. AGP allows a video card to have direct access to the system RAM, either enabling lower-cost video solutions to be directly built into a motherboard without having to include additional video RAM or enabling an AGP card to share the main system memory. High-performance cards will likely continue the trend of having more and more memory directly on the video card, which is especially important when running high-performance 3D video applications.

AGP allows the speed of the video card to pace the requirements for high-speed 3D graphics rendering as well as full motion video on the PC.

System Resources

System resources are the communications channels, addresses, and other signals used by hardware devices to communicate on the bus. At their lowest level, these resources typically include the following:

- Memory addresses
- IRQ (interrupt request) channels
- DMA (direct memory access) channels
- I/O port addresses

I have listed these roughly in the order you would experience problems with them. Memory conflicts are perhaps the most troublesome of these and certainly the most difficult to fully explain and overcome. These are discussed in Chapter 6, which focuses on the others listed here in the order you will likely have problems with them.

IRQs cause more problems than DMA because they are in much higher demand; virtually all cards use IRQ channels. Fewer problems exist with DMA channels because fewer cards use them, and there are usually more than enough channels to go around. I/O ports are used by all hardware devices on the bus, but there are technically 64KB of them, which means there are plenty to go around. With all these resources, you have to ensure that a unique card or hardware function uses each resource; in most cases they cannot or should not be shared.

These resources are required and used by many components of your system. Adapter cards need these resources to communicate with your system and accomplish their purposes. Not all adapter cards have the same resource requirements. A serial communications port, for example, needs an IRQ channel and I/O port address, whereas a sound card needs these resources and normally at least one DMA channel as well. Most network cards use an IRQ channel and an I/O port address, and some might also use a 16KB block of memory addresses.

As your system increases in complexity, the chance for resource conflicts increases. Modern systems with a number of additional devices can really push the envelope and become a configuration nightmare for the uninitiated. Sometimes under these situations the automatic configuration capability of Plug and Play can get confused or fail to optimally configure resources so that everything will work. Most adapter cards enable you to modify resource assignments by using the Plug and Play software that comes with the card or the Device Manager in Windows 9x and later, thus you can sometimes improve on a default configuration by making some changes. Even if the automatic configuration gets confused (which happens more often than it should), fortunately, in almost all cases a logical way to configure the system exists—once you know the rules.

Interrupts

Interrupt request channels, or hardware interrupts, are used by various hardware devices to signal the motherboard that a request must be fulfilled. This procedure is the same as a student raising his hand to indicate that he needs attention.

These interrupt channels are represented by wires on the motherboard and in the slot connectors. When a particular interrupt is invoked, a special routine takes over the system, which first saves all the CPU register contents in a stack and then directs the system to the interrupt vector table. This vector table contains a list of memory addresses that correspond to the interrupt channels. Depending on which interrupt was invoked, the program corresponding to that channel is run.

The pointers in the vector table point to the address of whatever software driver is used to service the card that generated the interrupt. For a network card, for example, the vector might point to the address of the network drivers that have been loaded to operate the card; for a hard disk controller, the vector might point to the BIOS code that operates the controller.

After the particular software routine finishes performing whatever function the card needed, the interrupt-control software returns the stack contents to the CPU registers, and the system then resumes whatever it was doing before the interrupt occurred.

Through the use of interrupts, your system can respond to external events in a timely fashion. Each time a serial port presents a byte to your system, an interrupt is generated to ensure that the system reads that byte before another comes in. Keep in mind that in some cases a port device—in particular, a modem with a 16550 or higher UART chip—might incorporate a byte buffer that allows multiple characters to be stored before an interrupt is generated.

Hardware interrupts are generally prioritized by their numbers; with some exceptions, the highest-priority interrupts have the lowest numbers. Higher-priority interrupts take precedence over lower-priority interrupts by interrupting them. As a result, several interrupts can occur in your system concurrently, each interrupt nesting within another.

If you overload the system—in this case, by running out of stack resources (too many interrupts were generated too quickly)—an internal stack overflow error occurs and your system halts. The message usually appears as `Internal stack overflow - system halted` at a DOS prompt. If you experience this type of system error and run DOS, you can compensate for it by using the `STACKS` parameter in your `CONFIG.SYS` file to increase the available stack resources. Most people will not see this error in Windows 9x/Me or Windows NT/2000/XP.

The ISA bus uses *edge-triggered* interrupt sensing, in which an interrupt is sensed by a changing signal sent on a particular wire located in the slot connector. A different wire corresponds to each possible hardware interrupt. Because the motherboard cannot recognize which slot contains the card that used an interrupt line and therefore generated the interrupt, confusion would result if more than one card were set to use a particular interrupt. Each interrupt, therefore, usually is designated for a single hardware device. Most of the time, interrupts cannot be shared.

Originally, IBM developed ways to share interrupts on the ISA bus, but few devices followed the necessary rules to make this a reality. The PCI bus inherently allows interrupt sharing; in fact, virtually all PCI cards are set to PCI interrupt A and share that interrupt on the PCI bus. The real problem is that there are technically two sets of hardware interrupts in the system: PCI interrupts and ISA interrupts. For PCI cards to work in a PC, the PCI interrupts are first mapped to ISA interrupts, which are then configured as nonshareable. Therefore, in many cases you must assign a nonconflicting interrupt for each card, even PCI cards. The conflict between assigning ISA IRQs for PCI interrupts caused many configuration problems for early users of PCI motherboards and continued to cause problems even after the development of Windows 95 and its Plug and Play technology.

The solution to the interrupt sharing problem for PCI cards was something called *PCI IRQ Steering*, which is supported in the more recent operating systems (starting with Windows 95 OSR 2.x) and BIOS. PCI IRQ Steering allows a plug-and-play operating system such as Windows to dynamically map or "steer" PCI cards (which almost all use PCI INTA#) to standard PC interrupts and allows several PCI cards to be mapped to the same interrupt. More information on PCI IRQ Steering is found in the section called "PCI Interrupts," later in this chapter.

Hardware interrupts are sometimes referred to as *maskable interrupts*, which means the interrupts can be masked or turned off for a short time while the CPU is used for other critical operations. It is up to the system BIOS and programs to manage interrupts properly and efficiently for the best system performance.

Because interrupts usually cannot be shared in an ISA bus system, you often run into conflicts and can even run out of interrupts when you are adding boards to a system. If two boards use the same IRQ to signal the system, the resulting conflict prevents either board from operating properly. The following sections discuss the IRQs that any standard devices use, as well as what might be free in your system.

8-Bit ISA Bus Interrupts

The PC and XT (the systems based on the 8-bit 8086 CPU) provide for eight different external hardware interrupts. Table 4.30 shows the typical uses for these interrupts, which are numbered 0–7.

Table 4.30 8-Bit ISA Bus Default Interrupt Assignments

IRQ	Function	Bus Slot
0	System Timer	No
1	Keyboard Controller	No
2	Available	Yes (8-bit)
3	Serial Port 2 (COM2:)	Yes (8-bit)
4	Serial Port 1 (COM1:)	Yes (8-bit)
5	Hard Disk Controller	Yes (8-bit)
6	Floppy Disk Controller	Yes (8-bit)
7	Parallel Port 1 (LPT1:)	Yes (8-bit)

If you have a system that has one of the original 8-bit ISA buses, you will find that the IRQ resources provided by the system present a severe limitation. Installing several devices that need the services of system IRQs in a PC/XT-type system can be a study in frustration because the only way to resolve the interrupt-shortage problem is to remove the adapter board that you need the least.

16-Bit ISA, EISA, and MCA Bus Interrupts

The introduction of the AT, based on the 286 processor, was accompanied by an increase in the number of external hardware interrupts the bus would support. The number of interrupts was doubled to 16 by using two Intel 8259 interrupt controllers, piping the interrupts generated by the second one through the unused IRQ 2 in the first controller. This arrangement effectively makes only 15 IRQ assignments available, and IRQ 2 effectively became inaccessible.

By routing all the interrupts from the second IRQ controller through IRQ 2 on the first, all these new interrupts are assigned a nested priority level between IRQ 1 and IRQ 3. Thus, IRQ 15 ends up having a higher priority than IRQ 3. Figure 4.64 shows how the two 8259 chips were wired to create the cascade through IRQ 2 on the first chip.

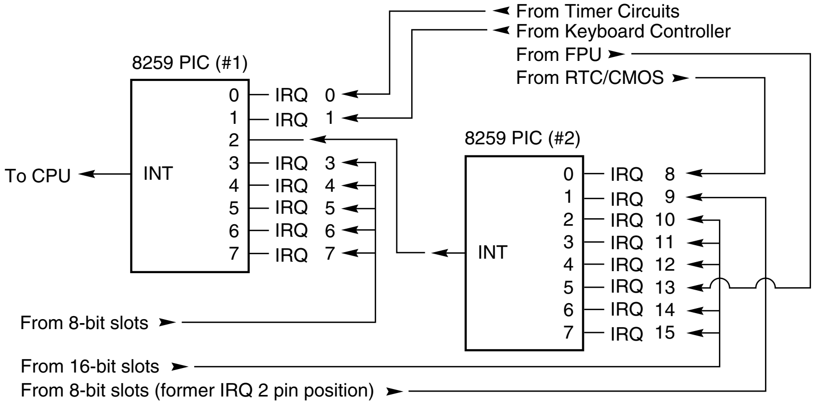

Figure 4.64 Interrupt controller cascade wiring.

To prevent problems with boards set to use IRQ 2, the AT system designers routed one of the new interrupts (IRQ 9) to fill the slot position left open after removing IRQ 2. This means that any card you install in a modern system that claims to use IRQ 2 is really using IRQ 9 instead. Some cards now label this selection as IRQ 2/9, whereas others might only call it IRQ 2 or IRQ 9. No matter what the labeling says, you must never set two cards to use that interrupt!

Table 4.31 shows the typical uses for interrupts in the 16-bit ISA and 32-bit PCI/AGP buses and lists them in priority order from highest to lowest. The obsolete EISA and MCA buses used a similar IRQ map.

Table 4.31 16/32-Bit ISA/PCI/AGP Default Interrupt Assignments

IRQ	Standard Function	Bus Slot	Card Type	Recommended Use
0	System Timer	No	-	-
1	Keyboard Controller	No	-	-
2	2nd IRQ Controller Cascade	No	-	-
8	Real-Time Clock	No	-	-
9	Avail. (as IRQ2 or IRQ9)	Yes	8/16-bit	Network Card
10	Available	Yes	16-bit	USB
11	Available	Yes	16-bit	SCSI Host Adapter
12	Mouse Port/Available	Yes	16-bit	Mouse Port
13	Math Coprocessor	No	—	—
14	Primary IDE	Yes	16-bit	Primary IDE (hard disks)
15	Secondary IDE	Yes	16-bit	2nd IDE (CD-ROM/Tape)
3	Serial 2 (COM2:)	Yes	8/16-bit	COM2:/Internal Modem
4	Serial 1 (COM1:)	Yes	8/16-bit	COM1:
5	Sound/Parallel 2 (LPT2:)	Yes	8/16-bit	Sound Card
6	Floppy Controller	Yes	8/16-bit	Floppy Controller
7	Parallel 1 (LPT1:)	Yes	8/16-bit	LPT1:

Notice that interrupts 0, 1, 2, 8, and 13 are not on the bus connectors and are not accessible to adapter cards. Interrupts 8, 10, 11, 12, 13, 14, and 15 are from the second interrupt controller and are accessible only by boards that use the 16-bit extension connector because this is where these wires are located. IRQ 9 is rewired to the 8-bit slot connector in place of IRQ 2, so IRQ 9 replaces IRQ 2 and, therefore, is available to 8-bit cards, which treat it as though it were IRQ 2.

Note

Although the 16-bit ISA bus has twice as many interrupts as systems that have the 8-bit ISA bus, you still might run out of available interrupts because only 16-bit adapters can use most of the newly available interrupts. Any 32-bit PCI adapter can be mapped to any ISA IRQs.

The extra IRQ lines in a 16-bit ISA system are of little help unless the adapter boards you plan to use enable you to configure them for one of the unused IRQs. Some devices are hard-wired so that they can use only a particular IRQ. If you have a device that already uses that IRQ, you must resolve the conflict before installing the second adapter. If neither adapter enables you to reconfigure its IRQ use, chances are that you cannot use the two devices in the same system.

PCI Interrupts

The PCI bus supports hardware interrupts (IRQs) that can be used by PCI devices to signal to the bus that they need attention. The four PCI interrupts are called INTA#, INTB#, INTC#, and INTD#. These INTx# interrupts are *level-sensitive*, which means that the electrical signaling enables them to be shared among PCI cards. In fact, all single device or single function PCI chips or cards that use only one interrupt must use INTA#. This is one of the rules in the PCI specification. If additional devices are within a chip or onboard a card, the additional devices can use INTB# through INTD#. Because there are very few multifunction PCI chips or boards, practically all the devices on a given PCI bus will be sharing INTA#.

For the PCI bus to function in a PC, the PCI interrupts must be mapped to ISA interrupts. Because ISA interrupts cannot be shared, in most cases each PCI card using INTA# on the PCI bus must be mapped to a different nonshareable ISA interrupt. For example, you could have a system with four PCI slots and four PCI cards installed, each using PCI interrupt INTA#. These cards would be each mapped to a different available ISA interrupt request, such as IRQ9, IRQ10, IRQ11, or IRQ5 in most cases.

Finding unique IRQs for each device on both the ISA and PCI buses has always been a problem; there simply aren't enough free ones to go around. Setting two ISA devices to the same IRQ has never been possible, but on most newer systems sharing IRQs between multiple PCI devices might be possible. Newer system BIOS as well as plug-and-play operating systems, such as Windows 95B (OSR 2) or later, Windows 98, and Windows 2000, all support a function known as PCI IRQ Steering. For this to work, both your system BIOS and operating system must support IRQ Steering. Older system BIOS and Windows 95 or 95A do not have support for PCI IRQ Steering.

Normally, the BIOS assigns unique IRQs to PCI devices. If your system supports PCI IRQ Steering and it is enabled, Windows assigns IRQs to PCI devices. Even when IRQ Steering is enabled, the BIOS still initially assigns IRQs to PCI devices. Although Windows has the capability to change these settings, it generally does not do so automatically, except where necessary to eliminate conflicts. If there are insufficient free IRQs to go around, IRQ Steering allows Windows to assign multiple PCI devices to a single IRQ, thus enabling all the devices in the system to function properly. Without IRQ Steering, Windows begins to disable devices after it runs out of free IRQs to assign.

To determine whether your system is using IRQ Steering, you can follow these steps:

1. Click Start, Settings, Control Panel, and then double-click System.
2. Click the Device Manager tab.
3. Double-click the System Devices branch.
4. Double-click PCI Bus, and then click the IRQ Steering tab. There will be a check that displays IRQ Steering as either Enabled or Disabled. If enabled, it also specifies where the IRQ table has been read from.

IRQ Steering is controlled by one of four routing tables Windows attempts to read. Windows searches for the tables in order and uses the first one it finds. You cannot control the order in which Windows searches for these tables, but by selecting or deselecting the Get IRQ Table Using check boxes, you can control which table Windows finds first by disabling the search for specific tables. Windows searches for the following tables:

- ACPI BIOS table
- MS Specification table
- Protected Mode PCIBIOS 2.1 table
- Real Mode PCIBIOS 2.1 table

Windows first tries to use the ACPI BIOS table to program IRQ Steering, followed by the MS Specification table, the Protected Mode PCIBIOS 2.1 table, and the Real Mode PCIBIOS 2.1 table. Windows 95 OSR2 and later versions only offer a choice for selecting the PCIBIOS 2.1 tables via a single check box, which is disabled by default. Under Windows 98, all IRQ table choices are selected by default, except the third one, which is the Protected Mode PCIBIOS 2.1 table.

If you are having a problem with a PCI device related to IRQ settings under Windows 95, try selecting the PCIBIOS 2.1 table and restarting. Under Windows 98, try clearing the ACPI BIOS table selection and restarting. If the problem persists, try selecting the Protected Mode PCIBIOS 2.1 table and restarting. You should select Get IRQ Table from Protected Mode PCIBIOS 2.1 Call only if a PCI device is not working properly. To access these settings in the Windows 98 Device Manager, do the following:

1. Click Start, Settings, Control Panel.
2. Open the System properties sheet.
3. Click the Device Manager tab.
4. Scroll down to the System Devices category, and double-click to open it.
5. Select PCI Bus and click Properties.
6. Click the IRQ Steering tab to see or change the current settings.

If IRQ Steering is shown as disabled in Device Manager, make sure the Use IRQ Steering check box is selected. After selecting this and restarting, if IRQ Steering is still showing as disabled, the IRQ routing table that must be provided by the BIOS to the operating system might be missing or contain errors. Check your BIOS setup to ensure PCI IRQ Steering is enabled. If there is still no success, you might have to select the Get IRQ Table from Protected Mode PCIBIOS 2.1 Call check box, or your BIOS might not support PCI bus IRQ Steering. Contact the manufacturer of your motherboard or BIOS to see whether your board or BIOS supports IRQ Steering.

On systems that have support for IRQ Steering, an IRQ Holder for PCI Steering might be displayed when you view the System Devices branch of Device Manager. This indicates that an IRQ has been mapped to PCI and is unavailable for ISA devices, even if no PCI devices are currently using the IRQ. To view IRQs programmed for PCI-mode, follow these steps:

1. Click Start, Settings, Control Panel, and then double-click System.
2. Click the Device Manager tab.
3. Double-click the System Devices branch.
4. Double-click the IRQ Holder for PCI Steering you want to view, and then click the Resources tab.

I have found this interrupt steering or mapping to be the source of a great deal of confusion. Even though PCI interrupts (INTx#) can be (and are by default) shared, each card or device that might be sharing a PCI interrupt must be mapped or steered to a unique ISA IRQ, which in turn cannot normally be shared. You can have several PCI devices mapped to the same ISA IRQ only if

- No ISA devices are using the IRQ.
- The BIOS and operating system support PCI IRQ Steering.
- PCI IRQ Steering is enabled.

Without PCI IRQ Steering support, the sharing capabilities of the PCI interrupts are of little benefit because all PCI-to-ISA IRQ assignments must then be unique. Without PCI IRQ Steering, you can easily run out of available ISA interrupts. If IRQ Steering is supported and enabled, multiple PCI devices will be capable of sharing a single IRQ, allowing for more system expansion without running out of available IRQs. Better support for IRQ Steering is one of the best reasons for upgrading to Windows 98, especially if you are using the original OSR1 release of 95.

Another source of confusion is that the interrupt listing shown in the Windows Device Manager might show the PCI to ISA interrupt mapping as multiple entries for a given ISA interrupt. One entry would be for the device actually mapped to the interrupt—for example, a built-in USB controller—whereas the other entry for the same IRQ would say `IRQ Holder for PCI Steering`. This latter entry, even though claiming to use the same IRQ, does not indicate a resource conflict; instead it represents the chipset circuitry putting a reservation on that interrupt for mapping purposes. This is part of the plug-and-play capabilities of PCI and the modern motherboard chipsets.

Note that you can have internal devices on the PCI bus even though all the PCI slots are free. For example, most systems today have two IDE controllers and a USB controller as devices on the PCI bus. Normally, the PCI IDE controllers are mapped to ISA interrupts 14 (primary IDE) and 15 (secondary IDE), whereas the USB controller can be mapped to the normally available ISA interrupts 9, 10, 11, and 5.

▶▶ See "Universal Serial Bus," p. 940.

The PCI bus enables two types of devices to exist, called *bus masters* (initiators) or *slaves* (targets). A bus master is a device that can take control of the bus and initiate a transfer. The target device is the intended destination of the transfer. Most PCI devices can act as both masters and targets, and to be compliant with the PC 97 and newer system design guides, all PCI slots must support bus master cards.

The PCI bus is an arbitrated bus: A central arbiter (part of the PCI bus controller in the motherboard chipset) governs all bus transfers, giving fair and controlled access to all the devices on the bus. Before a master can use the bus, it must first request control from the central arbiter, and then it is granted control for only a specified maximum number of cycles. This arbitration allows equal and fair access to all the bus master devices, prevents a single device from hogging the bus, and also prevents deadlocks because of simultaneous multiple device access. In this manner, the PCI bus acts much like a local area network (LAN), albeit one that is contained entirely within the system and runs at a much higher speed than conventional external networks between PCs.

IRQ Conflicts

Perhaps the most common IRQ conflict is the one between the integrated COM2: port found in most modern motherboards and an internal (card-based) modem. The problem stems from the fact that true PC card–based modems (not the so-called WinModems, which are software based) incorporate a serial port as part of the card's circuitry. This serial port is set as COM2: by default. Your PC sees this as having two COM2: ports, each using the same IRQ and I/O port address resources.

The solution to this problem is easy: Enter the system BIOS Setup and disable the built-in COM2: port in the system. While you are there, you might think about disabling the COM1: port also because you are unlikely to use it. Disabling unused COMx: ports is one of the best ways to free up a couple of IRQs for other devices to use.

Another common IRQ conflict involves serial (COM) ports. You might have noticed in the preceding two sections that two IRQs are set aside for two COM ports. IRQ 3 is used for COM2:, and IRQ 4 is used for COM1:. The problem occurs when you have more than two serial ports in a system. When people add COM3: and COM4: ports, they often don't set them to nonconflicting interrupts, which results in a conflict and the ports not working.

Contributing to the problem are poorly designed COM port boards that do not allow IRQ settings other than 3 or 4. What happens is that they end up setting COM3: to IRQ 4 (sharing it with COM1:), and COM4: to IRQ 3 (sharing it with COM2:). This is not acceptable because it prevents you from using the two COM ports on any one of the interrupt channels simultaneously. This was somewhat acceptable under plain DOS because single-tasking (running only one program at a time) was the order of the day, but it is totally unacceptable with Windows and OS/2. If you must share IRQs, you can usually get away with sharing devices on the same IRQ as long as they use different COM ports. For instance, a scanner and an internal modem could share an IRQ, although if the two devices are used simultaneously, a conflict results.

The best solution is to purchase a multiport serial I/O card that allows nonconflicting interrupt settings or an intelligent card with its own processor that can handle the multiple ports onboard and use only one interrupt in the system.

▶▶ See "Serial Ports," p. 924.

If a device listed in the table is not present, such as the motherboard mouse port (IRQ 12) or parallel port 2 (IRQ 5), you can consider those interrupts as available. For example, a second parallel port is a rarity, and most systems have a sound card installed and set for IRQ 5. Also, on most systems IRQ 15 is assigned to a secondary IDE controller. If you do not have a second IDE hard drive, you could disable the secondary IDE controller to free up that IRQ for another device.

Note that an easy way to check your interrupt settings is to use the Device Manager in Windows 95/98, NT, or Windows 2000. By double-clicking the Computer Properties icon in the Device Manager, you can get concise lists of all used system resources. Microsoft has also included a program called HWDIAG on Windows 95B; Windows 98 and above feature the System Information program. HWDIAG and System Information do an excellent job of reporting system resource usage, as well as details about device drivers and Windows Registry entries for each hardware component.

DMA Channels

Direct Memory Access (DMA) channels are used by high-speed communications devices that must send and receive information at high speed. A serial or parallel port does not use a DMA channel, but a sound card or SCSI adapter often does. DMA channels sometimes can be shared if the devices are not the type that would need them simultaneously. For example, you can have a network adapter and a tape backup adapter sharing DMA channel 1, but you cannot back up while the network is running. To back up during network operation, you must ensure that each adapter uses a unique DMA channel.

Note

There are several types of DMA in a modern PC. The DMA channels referred to in this section involve the ISA bus. Other buses, such as the ATA/IDE bus used by hard drives, have different DMA use. The DMA channels explained here don't involve your ATA/IDE drives, even if they are set to use DMA or Ultra DMA transfers.

8-Bit ISA Bus DMA Channels

In the 8-bit ISA bus, four DMA channels support high-speed data transfers between I/O devices and memory. Three of the channels are available to the expansion slots. Table 4.32 shows the typical uses of these DMA channels.

Table 4.32 8-Bit ISA Default DMA-Channel Assignments

DMA	Standard Function	Bus Slot
0	Dynamic RAM Refresh	No
1	Available	Yes (8-bit)
2	Floppy disk controller	Yes (8-bit)
3	Hard disk controller	Yes (8-bit)

Because most systems typically have both a floppy and hard disk drive, only one DMA channel is available in 8-bit ISA systems.

16-Bit ISA DMA Channels

Since the introduction of the 286 CPU, the ISA bus has supported eight DMA channels, with seven channels available to the expansion slots. Similar to the expanded IRQ lines described earlier in this chapter, the added DMA channels were created by cascading a second DMA controller to the first one. DMA channel 4 is used to cascade channels 0–3 to the microprocessor. Channels 0–3 are available for 8-bit transfers, and channels 5–7 are for 16-bit transfers only. Table 4.33 shows the typical uses for the DMA channels.

Table 4.33 16-Bit ISA Default DMA-Channel Assignments

DMA	Standard Function	Bus Slot	Card Type	Transfer	Recommended Use
0	Available	Yes	16-bit	8-bit	Sound
1	Available	Yes	8/16-bit	8-bit	Sound
2	Floppy Disk Controller	Yes	8/16-bit	8-bit	Floppy Controller
3	Available	Yes	8/16-bit	8-bit	LPT1: in ECP Mode
4	1st DMA Controller Cascade	No	—	16-bit	—
5	Available	Yes	16-bit	16-bit	Sound
6	Available	Yes	16-bit	16-bit	Available
7	Available	Yes	16-bit	16-bit	Available

Note that PCI adapters don't use these ISA DMA channels; these are only for ISA cards. However, some PCI cards emulate the use of these DMA channels (such as sound cards) to work with older software.

The only standard DMA channel used in all systems is DMA 2, which is universally used by the floppy controller. DMA 4 is not usable and does not appear in the bus slots. DMA channels 1 and 5 are most commonly used by ISA sound cards, such as the Sound Blaster 16, or by newer PCI sound cards that emulate an older one for backwards compatibility. These cards use both an 8- and a 16-bit DMA channel for high-speed transfers.

Note

Although DMA channel 0 appears in a 16-bit slot connector extension and therefore can be used by only a 16-bit card, it performs only 8-bit transfers! Because of this, you generally don't see DMA 0 as a choice on 16-bit cards. Most 16-bit cards (such as SCSI host adapters) that use DMA channels have their choices limited to DMA 5–7.

I/O Port Addresses

Your computer's I/O ports enable communications between devices and software in your system. They are equivalent to two-way radio channels. If you want to talk to your serial port, you need to know on which I/O port (radio channel) it is listening. Similarly, if you want to receive data from the serial port, you need to listen on the same channel it is transmitting on.

Unlike IRQs and DMA channels, our systems have an abundance of I/O ports. There are 65,535 ports to be exact—numbered from 0000h to FFFFh—and this is an artifact of the Intel processor design more than anything else. Even though most devices use up to 8 ports for themselves, with that many to spare, you won't run out anytime soon. The biggest problem you have to worry about is setting two devices to use the same port.

Most modern plug-and-play systems resolve any port conflicts and select alternative ports for one of the conflicting devices.

One confusing issue is that I/O ports are designated by hexadecimal addresses similar to memory addresses. They are not memory; they are ports. The difference is that when you send data to memory address 1000h, it gets stored in your SIMM or DIMM memory. If you send data to I/O port address 1000h, it gets sent out on the bus on that "channel," and anybody listening in would then "hear" it. If nobody was listening to that port address, the data would reach the end of the bus and be absorbed by the bus terminating resistors.

Driver programs are primarily what interact with devices at the various port addresses. The driver must know which ports the device is using to work with it, and vice versa. That is not usually a problem because the driver and device both come from the same company.

Motherboard and chipset devices usually are set to use I/O port addresses from 0h to FFh, and all other devices use from 100h to FFFFh. Table 4.34 shows the commonly used motherboard and chipset-based I/O port usage.

Table 4.34 Motherboard and Chipset-Based Device Port Addresses

Address (hex)	Size	Description
0000–000F	16 bytes	Chipset - 8237 DMA 1
0020–0021	2 bytes	Chipset - 8259 interrupt controller 1
002E–002F	2 bytes	Super I/O controller configuration registers
0040–0043	4 bytes	Chipset - Counter/Timer 1
0048–004B	4 bytes	Chipset - Counter/Timer 2

Table 4.34 Continued

Address (hex)	Size	Description
0060	1 byte	Keyboard/Mouse controller byte - reset IRQ
0061	1 byte	Chipset - NMI, speaker control
0064	1 byte	Keyboard/Mouse controller, CMD/STAT byte
0070, bit 7	1 bit	Chipset - Enable NMI
0070, bits 6:0	7 bits	MC146818 - Real-time clock, address
0071	1 byte	MC146818 - Real-time clock, data
0078	1 byte	Reserved - Board configuration
0079	1 byte	Reserved - Board configuration
0080–008F	16 bytes	Chipset - DMA page registers
00A0–00A1	2 bytes	Chipset - 8259 interrupt controller 2
00B2	1 byte	APM control port
00B3	1 byte	APM status port
00C0–00DE	31 bytes	Chipset - 8237 DMA 2
00F0	1 byte	Math Coprocessor Reset Numeric Error

To find out exactly which port addresses are being used on your motherboard, consult the board documentation or look up these settings in the Windows Device Manager.

Bus-based devices typically use the addresses from 100h on up. Table 4.35 lists the commonly used bus-based device addresses and some common adapter cards and their settings.

Table 4.35 Bus-Based Device Port Addresses

Address (hex)	Size	Description
0130–0133	4 bytes	Adaptec SCSI adapter (alternate)
0134–0137	4 bytes	Adaptec SCSI adapter (alternate)
0168–016F	8 bytes	Fourth IDE interface
0170–0177	8 bytes	Secondary IDE interface
01E8–01EF	8 bytes	Third IDE interface
01F0–01F7	8 bytes	Primary IDE / AT (16-bit) hard disk controller
0200–0207	8 bytes	Gameport or joystick adapter
0210–0217	8 bytes	IBM XT expansion chassis
0220–0233	20 bytes	Creative Labs Sound Blaster 16 audio (default)
0230–0233	4 bytes	Adaptec SCSI adapter (alternate)
0234–0237	4 bytes	Adaptec SCSI adapter (alternate)
0238–023B	4 bytes	MS bus mouse (alternate)
023C–023F	4 bytes	MS bus mouse (default)
0240–024F	16 bytes	SMC Ethernet adapter (default)
0240–0253	20 bytes	Creative Labs Sound Blaster 16 audio (alternate)
0258–025F	8 bytes	Intel above board
0260–026F	16 bytes	SMC Ethernet adapter (alternate)

Table 4.35 Continued

Address (hex)	Size	Description
0260–0273	20 bytes	Creative Labs Sound Blaster 16 audio (alternate)
0270–0273	4 bytes	Plug and Play I/O read ports
0278–027F	8 bytes	Parallel port 2 (LPT2)
0280–028F	16 bytes	SMC Ethernet adapter (alternate)
0280–0293	20 bytes	Creative Labs Sound Blaster 16 audio (alternate)
02A0–02AF	16 bytes	SMC Ethernet adapter (alternate)
02C0–02CF	16 bytes	SMC Ethernet adapter (alternate)
02E0–02EF	16 bytes	SMC Ethernet adapter (alternate)
02E8–02EF	8 bytes	Serial port 4 (COM4)
02EC–02EF	4 bytes	Video, 8514, or ATI standard ports
02F8–02FF	8 bytes	Serial port 2 (COM2)
0300–0301	2 bytes	MPU-401 MIDI port (secondary)
0300–030F	16 bytes	SMC Ethernet adapter (alternate)
0320–0323	4 bytes	XT (8-bit) hard disk controller
0320–032F	16 bytes	SMC Ethernet adapter (alternate)
0330–0331	2 bytes	MPU-401 MIDI port (default)
0330–0333	4 bytes	Adaptec SCSI adapter (default)
0334–0337	4 bytes	Adaptec SCSI adapter (alternate)
0340–034F	16 bytes	SMC Ethernet adapter (alternate)
0360–036F	16 bytes	SMC Ethernet adapter (alternate)
0366	1 byte	Fourth IDE command port
0367, bits 6:0	7 bits	Fourth IDE status port
0370–0375	6 bytes	Secondary floppy controller
0376	1 byte	Secondary IDE command port
0377, bit 7	1 bit	Secondary floppy controller disk change
0377, bits 6:0	7 bits	Secondary IDE status port
0378–037F	8 bytes	Parallel Port 1 (LPT1)
0380–038F	16 bytes	SMC Ethernet adapter (alternate)
0388–038B	4 bytes	Audio - FM synthesizer
03B0–03BB	12 bytes	Video, Mono/EGA/VGA standard ports
03BC–03BF	4 bytes	Parallel port 1 (LPT1) in some systems
03BC–03BF	4 bytes	Parallel port 3 (LPT3)
03C0–03CF	16 bytes	Video, EGA/VGA standard ports
03D0–03DF	16 bytes	Video, CGA/EGA/VGA standard ports
03E6	1 byte	Third IDE command port
03E7, bits 6:0	7 bits	Third IDE status port
03E8–03EF	8 bytes	Serial port 3 (COM3)
03F0–03F5	6 bytes	Primary floppy controller
03F6	1 byte	Primary IDE command port
03F7, bit 7	1 bit	Primary floppy controller disk change

Table 4.35 Continued

Address (hex)	Size	Description
03F7, bits 6:0	7 bits	Primary IDE status port
03F8–03FF	8 bytes	Serial port 1 (COM1)
04D0–04D1	2 bytes	Edge/level triggered PCI interrupt controller
0530–0537	8 bytes	Windows sound system (default)
0604–060B	8 bytes	Windows sound system (alternate)
0678–067F	8 bytes	LPT2 in ECP mode
0778–077F	8 bytes	LPT1 in ECP mode
0A20–0A23	4 bytes	IBM Token-Ring adapter (default)
0A24–0A27	4 bytes	IBM Token-Ring adapter (alternate)
0CF8–0CFB	4 bytes	PCI configuration address registers
0CF9	1 byte	Turbo and reset control register
0CFC–0CFF	4 bytes	PCI configuration data registers
FF00–FF07	8 bytes	IDE bus master registers
FF80–FF9F	32 bytes	Universal serial bus
FFA0–FFA7	8 bytes	Primary bus master IDE registers
FFA8–FFAF	8 bytes	Secondary bus master IDE registers

To find out exactly what your devices are using, again I recommend consulting the documentation for the device or looking up the device in the Windows Device Manager. Note that the documentation for some devices might list only the starting address instead of the full range of I/O port addresses used.

Virtually all devices on your system buses use I/O port addresses. Most of these are fairly standardized, meaning you won't often have conflicts or problems with these settings. In the next section, you learn more about working with I/O addresses.

Resolving Resource Conflicts

The resources in a system are limited. Unfortunately, the demands on those resources seem to be unlimited. As you add more and more adapter cards to your system, you will find that the potential for resource conflicts increases. If your system is fully PnP-compatible, potential conflicts should be resolved automatically, but often are not.

How do you know whether you have a resource conflict? Typically, one of the devices in your system stops working. Resource conflicts can exhibit themselves in other ways, though. Any of the following events could be diagnosed as a resource conflict:

- A device transfers data inaccurately.
- Your system frequently locks up.
- Your sound card doesn't sound quite right.
- Your mouse doesn't work.
- Garbage appears on your video screen for no apparent reason.
- Your printer prints gibberish.
- You cannot format a floppy disk.
- The PC starts in Safe mode (Windows 9x).

Windows 9x/Me and Windows 2000/XP also show conflicts by highlighting a device in yellow or red in the Device Manager representation. By using the Windows Device Manager, you can usually spot the conflicts quickly.

In the following sections, you learn some of the steps you can take to head off resource conflicts or track them down when they occur.

Caution

Be careful in diagnosing resource conflicts; a problem might not be a resource conflict at all, but a computer virus. Many computer viruses are designed to exhibit themselves as glitches or periodic problems. If you suspect a resource conflict, it might be worthwhile to run a virus check first to ensure that the system is clean. This procedure could save you hours of work and frustration.

One way to resolve conflicts is to help prevent them in the first place. Especially if you are building up a new system, you can take several steps to avoid problems. One is to avoid using older ISA devices. By definition, they cannot share IRQs, and that is the resource most in demand. PCI (and AGP) cards can share IRQs with IRQ Steering and as such are a much better choice.

Another way you can help is to install cards in a particular sequence, and not all at once. Modifying the installation sequence often helps because many cards can use only one or two out of a predefined selection of IRQs that is specific to each brand or model of card. By installing the cards in a controlled sequence, the plug-and-play software can more easily work around IRQ conflicts caused by the default configurations of different cards.

The first time you start up a new system you have assembled or done major upgrades on, the first thing you should check is the BIOS Setup. If you have a setting for PnP Operating System in your BIOS, be sure it is enabled if you are running an operating system with plug-and-play support, such as Windows 9x/Me/2000. Otherwise, make sure it's disabled if you are running an OS that is not plug-and-play, such as Windows NT.

On initial startup I recommend a minimum configuration with only the graphics card, memory, and storage drives (floppy, hard disk, CD-ROM, and DVD). This allows for the least possibility of system conflicts in the initial configuration. If your motherboard came with a CD including drivers specific to the chipset or other built-in features of the board, now is the time to load or install them. Complete the configuration of all built-in devices before installing any other cards or external devices.

After the basic system has been configured (and after you have successfully loaded your operating system and any updates or patches), you can then begin adding one device at a time in a specific order. So, you will power down, install the new device, power up, and proceed to install any necessary drivers and configure the device. You'll probably have to restart your system after you are done to fully complete the configuration.

Tip

I sometimes recommend that between installing devices you enter the Device Manager in Windows and print out the resource settings as they are configured at the time. This way you have a record of how the configuration changes during the entire device installation and configuration process.

Here's the loading sequence for additional cards:

1. Sound card
2. Internal or external modem
3. Network card

4. Auxiliary video devices, such as MPEG decoders, 3D accelerators, and so on
5. SCSI adapter
6. Anything else

Normally, using this controlled sequence of configuring or building up your system results in easier integration with less conflicts and configuration hassles.

Resolving Conflicts Manually

In the past, the only way to resolve conflicts manually was to take the cover off your system and start changing switches or jumper settings on the adapter cards. Fortunately, this is a bit easier with plug-and-play because all the configuration is done via the Device Manager software included in the operating system. Although some early plug-and-play cards also had jumper switches or setup options to enable them to be configured manually, this feature was found primarily on ISA PnP-compatible cards.

Be sure you write down or print out your current system settings before you start making changes. That way, you will know where you began and can go back to the original configuration (if necessary).

Finally, dig out the manuals for all your adapter boards; you might need them. Additionally, you could look for more current information online at the manufacturers' Web sites.

Now you are ready to begin your detective work. As you try various resource settings, keep the following questions in mind; the answers will help you narrow down the conflict areas:

- *When did the conflict first become apparent?* If the conflict occurred after you installed a new adapter card, that new card probably is causing the conflict. If the conflict occurred after you started using new software, the software probably uses a device that is taxing your system's resources in a new way.
- *Are two similar devices in your system that do not work?* For example, if your modem, integrated serial ports, or mouse—devices that use a COM port—do not work, chances are good that these devices are conflicting with each other.
- *Have other people had the same problem, and if so, how did they resolve it?* Public forums—such as those on CompuServe, Internet newsgroups, and America Online—are great places to find other users who might be able to help you solve the conflict.

Whenever you make changes in your system, reboot and see whether the problem persists. When you believe that you have solved the problem, be sure to test all your software. Fixing one problem often seems to cause another to crop up. The only way to ensure that all problems are resolved is to test everything in your system.

One of the best pieces of advice I can give you is to try changing one thing at a time, and then retest. That is the most methodical and simplest way to isolate a problem quickly and efficiently.

As you attempt to resolve your resource conflicts, you should work with and update a system-configuration template, as discussed in the following section.

Using a System-Configuration Template

A *system-configuration template* is helpful because remembering something that is written down is easier than keeping it in your head. To create a configuration template, you need to start writing down which resources are used by which parts of your system. Then, when you need to make a change or add an adapter, you can quickly determine where conflicts might arise. You can also use the Windows 9x/Me/2000 Device Manager to list and print this information.

I like to use a worksheet split into three main areas—one for interrupts, another for DMA channels, and a middle area for devices that do not use interrupts. Each section lists the IRQ or DMA channel on the left and the I/O port device range on the right. This way, I get the clearest picture of which resources are used and which ones are available in a given system.

Page 332 shows the system-configuration template I have developed over the years and still use almost daily.

This type of configuration sheet is resource based instead of component based. Each row in the template represents a different resource and lists the component using the resource as well as the resources used. The chart has pre-entered all the fixed items in a modern PC for which the configuration cannot be changed.

To fill out this type of chart, you would perform the following steps:

1. Enter the default resources used by standard components, such as serial and parallel ports, disk controllers, and video. You can use the filled-out example I have provided to see how most standard devices are configured.
2. Enter the default resources used by additional add-on components, such as sound cards, SCSI cards, network cards, proprietary cards, and so on.
3. Change any configuration items that are in conflict. Try to leave built-in devices at their default settings, as well as sound cards. Other installed adapters might have their settings changed, but be sure to document the changes.

Of course, a template such as this is best used when first installing components, not after. After you have it completely filled out to match your system, you can label it and keep it with the system. When you add any more devices, the template will be your guide as to how any new devices should be configured.

Note

Thanks to plug-and-play configuration, the days of fixed IRQ and other hardware resources are receding into the past. Don't be surprised if your system has assigned different IRQ, I/O port address, or DMA settings after you install a new card. That's why I recommend recording information both before and after you add a new device to your system.

You also might want to track which PCI slot is used by a particular card because some systems convert PCI IRQs to different ISA IRQs depending on which slot is used for a card. Also, some systems pair PCI slots, assigning cards installed in both paired slots to the same ISA IRQ.

The example on page 333 is the same template filled out for a typical modern PC system.

1. Represents a resource setting that had to be changed to resolve a conflict

As you can see from this template, only one IRQ and two DMA channels remain available, and that would be *no* IRQs if I enabled the USB on the motherboard! As you can see, interrupt shortages are a big problem in modern systems. In that case, I would probably find a way to recover one of the other interrupts; for example, I am not really using COM1, so I could disable that port and gain back IRQ 4. In this sample configuration, the primary and secondary IDE connectors were built into the motherboard:

- Floppy controller
- Two serial ports
- One parallel port

Whether these devices are built into the motherboard or on a separate card makes no difference because the resource allocations are the same in either case. All default settings usually are used for these devices and are indicated in the completed configuration. Next, the accessory cards were configured. In this example, the following cards were installed:

- SVGA video card (ATI Mach 64)
- Sound card (Creative Labs Sound Blaster 16)
- SCSI host adapter (Adaptec AHA-1542CF)
- Network interface card (SMC EtherEZ)

It helps to install the cards in this order. Start with the video card; next, add the sound card. Because of problems with software that must be configured to the sound card, it is best to install it early and ensure that only default settings are used. It is better to change settings on other cards than the sound card.

After the sound card, the SCSI adapter was installed; however, the default I/O port addresses (330–331) and DMA channel (DMA 5) used were in conflict with other cards (mainly the sound card). These settings were changed to their next logical settings that did not cause a conflict.

Finally, the network card was installed, which also had default settings that conflicted with other cards. In this case, the Ethernet card came preconfigured to IRQ 3, which was already in use by COM2:. The solution was to change the setting, and IRQ 9 was the next logical choice in the card's configuration settings.

Even though this is a fully loaded configuration, only three individual items among all the cards had to be changed to achieve an optimum system configuration. As you can see, using a configuration template such as the one shown can make what would otherwise be a jumble of settings lay out in an easy-to-follow manner. The only real problems you will run into after you work with these templates are cards that do not allow for enough adjustment in their settings or cards that are lacking in documentation. As you can imagine, you will need the documentation for each adapter card, as well as the motherboard, to accurately complete a configuration table such as the one shown.

Tip

Do not rely too much on third-party DOS-based software diagnostics, such as MSD.EXE, which claim to be capable of showing hardware settings such as IRQ and I/O port settings. Even though they can be helpful in certain situations, they are often wrong with respect to at least some of the information they display about your system. One or two items shown incorrectly can be very troublesome if you believe the incorrect information and configure your system based on it!

A much better utility to view these settings is the Device Manager built into Windows 9x/Me/2000. With plug-and-play hardware, it not only reports settings, but it allows you to change them. On older legacy hardware, you can view the settings but not change them. To change the settings of legacy (non–plug-and-play) hardware, you must manually move jumpers or switches and run the special configuration software that came with the card. Consult the card manufacturer or documentation for more information.

Heading Off Problems: Special Boards

A number of devices that you might want to install in a computer system require IRQ lines or DMA channels, which means that a world of conflict could be waiting in the box the device comes in. As mentioned in the preceding section, you can save yourself problems if you use a system-configuration template to keep track of the way your system is configured.

You also can save yourself trouble by carefully reading the documentation for a new adapter board before you attempt to install it. The documentation details the IRQ lines the board can use as well as its DMA-channel requirements. In addition, the documentation details the adapter's upper-memory needs for ROM and adapter.

The following sections describe some of the conflicts you might encounter when you install today's most popular adapter boards. Although the list of adapter boards covered in these sections is far from comprehensive, the sections serve as a guide to installing complex hardware with minimum hassle. Included are tips on soundboards, SCSI host adapters, and network adapters.

Sound Cards

Sound cards are probably the biggest single resource hog in your system. They typically use at least one IRQ, two DMA channels, and multiple I/O port address ranges. This is because a sound card is actually several different pieces of hardware all on one board. Most sound cards, including PCI-based models, emulate the Sound Blaster 16 from Creative Labs.

Table 4.36 shows the default resources used by a typical PCI sound card, the Creative Labs SB512. Because sound cards are multifunction devices, each function is listed separately as it appears in the Windows Device Manager.

Table 4.36 Default Resources Used by Creative Labs SB512

Device	IRQ	I/O Port Address	16-bit DMA Channel	8-bit DMA Channel
Sound Blaster 16 emulation	5	0220–022F 0330–0331[1] 0388–038B[2]	5	1
Creative Multimedia Interface	N/A	D400–D407	N/A	N/A
Creative Gameport Joystick	N/A	0200–0207	N/A	N/A
Creative SB512	9[3]	C860–C87F	N/A	N/A

1. *Used for MIDI interface*
2. *Used for FM Synthesis*
3. *Varies with system and PCI expansion slot used*

Although other brands of sound cards might use a slightly different configuration, the pattern is the same; Sound Blaster emulation requires a large number of resources. Even if SB emulation isn't used (you might be able to disable it if you no longer play DOS games), the card still uses a single IRQ and several I/O port address ranges. If you take the time to read your soundboard's documentation and determine its communications-channel needs, compare those needs to the IRQ lines and DMA channels that already are in use in your system, and then change the settings of the other adapters to avoid conflicts with the sound card, your installation will go quickly and smoothly. Unfortunately, many vendors no longer provide detailed information on their plug-and-play–compatible cards. That's why you need to install the sound card **first** and use the system resource map to record which settings the card uses before you install other cards.

Tip

The best advice I can give you for installing a sound card is to put the sound card in before all other cards—except for video. In other words, let the sound card retain all its default settings if you can. Try to change the settings of other adapters when a conflict with the sound card arises. The problem here is that many older programs that use sound are very poorly written with respect to supporting alternative resource settings on sound cards. Save yourself some grief, and let the sound card have its way!

Even the latest sound cards can have problems if they're installed after other cards. I know a user who had to remove all his plug-and-play cards before his system would recognize his plug-and-play sound card.

One example of a potential soundboard conflict is the combination of a Sound Blaster 16 and an Adaptec SCSI adapter, as I noted earlier in this chapter. The Sound and SCSI adapters conflict on DMA 5 as well as on I/O ports 330–331. Rather than changing the settings of the sound card, it is best to alter the SCSI adapter to the next available settings that will not conflict with the sound card or anything else. The final settings are shown in the previous configuration template.

The cards in question (Sound Blaster 16 and AHA-1542CF) are not singled out here because there is something wrong with them, but instead because they happen to be very popular cards of their respective types and, as such, often are paired together.

Most people would be using PCI versions of these cards today, but they still require the same types of resource settings with the only exception being DMA channels. Unfortunately, it wasn't DMA channels that we were really running out of! The interrupt shortage continues even with PCI cards because they must be mapped to ISA IRQs. The real solution to the ISA IRQ battle is now arriving, as most new systems are shipping with motherboards that lack ISA slots and break ties with that bus forever. When that happens, we will be free of the interrupt restrictions we have been under for so many years.

Tip

The newer PCI sound cards are largely incompatible with older DOS-based software because they don't use DMA channels like their ISA counterparts. If you don't update your software to 32-bit Windows versions, you won't be able to use these newer PCI bus sound cards. Most of the newer PCI cards do include an emulation program that allows the card to work with older DMA-dependent software, but the results are often problematic.

For the best results, use the PC/PCI connector found on some motherboards to connect a patch cable to a PC/PCI-compatible sound card. The PC/PCI connector enables the sound card to use ISA-style DMA channels without clumsy emulation software.

SCSI Adapter Boards

SCSI adapter boards use more resources than just about any other type of add-in device except perhaps a sound card. They often use resources that are in conflict with sound cards or network cards, especially if the card has an onboard BIOS for handling bootable drives. A typical ISA SCSI host adapter with onboard BIOS requires an IRQ line, a DMA channel, a range of I/O port addresses, plus a

16KB range of unused upper memory for its ROM and possible scratch-pad RAM use. Even a simple SCSI host adapter designed for use with scanners still requires an IRQ and a range of I/O port addresses. Fortunately, the typical SCSI adapter is also easy to reconfigure, and changing any of these settings should not affect performance or software operation. PCI-based SCSI host adapters require all of the above, except for the DMA channel.

Before installing a SCSI adapter, be sure to read the documentation for the card, and ensure that any IRQ lines, DMA channels, I/O ports, and upper memory the card needs are available. If the system resources the card needs are already in use, use your system-configuration template to determine how you can alter the settings on the SCSI card or other cards to prevent any resource conflicts before you attempt to plug in the adapter card.

Network Interface Cards

Networks are becoming more and more popular all the time, thanks to the rise of easy-to-configure small office/home office networks and the use of network cards to connect to broadband Internet devices such as cable and DSL modems. A typical network adapter does not require as many resources as some of the other cards discussed here, but it requires at least a range of I/O port addresses and an interrupt. Most network interface cards (NICs) also require a 16KB range of free upper memory to be used for the RAM transfer buffer on the network card. As with any other cards, be sure that all these resources are unique to the card and are not shared with any other devices.

Multiple-COM-Port Adapters

A serial port adapter usually has two or more ports onboard. These COM ports require an interrupt and a range of I/O ports each. There aren't too many problems with the I/O port addresses because the ranges used by up to four COM ports in a system are fairly well defined. The real problem is with the interrupts. Most older installations of more than two serial ports have any additional ones sharing the same interrupts as the first two. This is incorrect and causes nothing but problems with software that runs under Windows or OS/2. With these older boards, ensure that each serial port in your system has a unique I/O port address range and, more importantly, a unique interrupt setting.

Many newer multiport adapter cards—such as those offered by Byte Runner Technologies—allow "intelligent" interrupt sharing among ports. In some cases, you can have up to 12 COM port settings without conflict problems. Check with your adapter card's manufacturer to determine whether it allows for automatic or "intelligent" interrupt sharing.

Although most people have problems incorrectly trying to share interrupts when installing more than two serial ports in a system, a fairly common problem exists with the I/O port addressing that should be mentioned. Many of the high-performance video chipsets, such as those from S3 Inc., and ATI, use some additional I/O port addresses that conflicts with the standard I/O port addresses used by COM4:.

In the sample system configuration just covered, you can see that the ATI video card uses some additional I/O port addresses, specifically 2EC–2EF. This is a problem because COM4: usually is configured as 2E8–2EF, which overlaps with the video card. The video cards that use these addresses are not normally adjustable for this setting, so you either must change the address of COM4: to a nonstandard setting or disable COM4: and restrict yourself to using only three serial ports in the system. If you do have a serial adapter that supports nonstandard I/O address settings for the serial ports, you must ensure that those settings are not used by other cards, and you must inform any software or drivers, such as those in Windows, of your nonstandard settings.

Universal Serial Bus

USB ports are now found on most motherboards, and Windows 98, Windows Me, Windows 2000, and Windows XP provide you with a wide range of operating systems that support them properly. One potential problem is that USB takes another interrupt from your system, and many computers either don't have any free or are down to their last one. If your system supports PCI IRQ Steering, this shouldn't be much of a problem because the IRQ used by your USB controller should be sharable with other PCI devices. If you are out of interrupts, you should look at what other devices you can disable (such as COM or LPT ports) to gain back a necessary interrupt for other devices.

The big advantage of USB from an IRQ or a resource perspective is that the USB bus uses only one IRQ no matter how many devices (up to 127) are attached. Therefore, you can freely add or remove devices from the USB without worrying about running out of resources or having resource conflicts.

If you aren't using any USB devices, you should turn off the port using your motherboard CMOS Setup so that the IRQ it was using will be freed. As we continue move to USB-based keyboards, mice, modems, printers, and so on, the IRQ shortage will be less of a problem. As we have already seen, the elimination of the ISA bus in our systems will also go a long way toward solving this problem as well.

Miscellaneous Boards

Some video cards ship with advanced software that allows special video features, such as oversized desktops, custom monitors, switch modes on-the-fly, and so on. Unfortunately, this software requires that the card be configured to use an IRQ. If your video card doesn't require an IRQ, I suggest you dispense with this unnecessary software and configure the card to free up the interrupt for other devices. However, keep in mind that many of the latest 3D accelerators must use an IRQ to enable their bus-mastering feature to work correctly. See your video card's manual for details.

Also related to video is the use of an MPEG decoder add-on card that works in addition to your normal graphics adapter. These are used more in specialized video production and editing and in playing DVD movies; however, they do use additional system resources that must be available. If your CPU runs at speeds above 300MHz and you have an AGP video card, you can probably use your video card for DVD playback and remove the MPEG decoder card. You will need a DVD player program, which might be supplied with your video card. See your video card's manual for details.

Plug-and-Play Systems

Plug and Play (PnP) represents a major revolution in recent interface technology. PnP first came on the market in 1995, and most motherboards and adapter cards since 1996 take advantage of it. Prior to that, PC users were forced to muddle through a nightmare of DIP switches and jumpers every time they wanted to add new devices to their systems. The results, all too often, were system resource conflicts and nonfunctioning cards.

PnP was not an entirely new concept. It was a key design feature of MCA and EISA interfaces that preceded it by almost 10 years, but the limited appeal of MCA and EISA meant that they never became true de facto industry standards. Therefore, mainstream PC users still had to worry about I/O addresses, DMA channels, and IRQ settings. Early PCI-based systems also used a form of PnP configuration, but because there was no provision for managing conflicts between PCI and ISA cards, many users still had configuration problems. But now that PnP has become prevalent, worry-free hardware setup is available to all computer buyers.

For PnP to work, the following components are desired:

- PnP hardware
- PnP BIOS
- PnP operating system

Each of these components needs to be PnP-compatible, meaning that it complies with the PnP specifications.

The Hardware Component

The *hardware component* refers to both computer systems and adapter cards. The term does not mean, however, that you cannot use your older ISA adapter cards (referred to as *legacy cards*) in a PnP system. You can use these cards; in fact, your PnP BIOS automatically reassigns PnP-compatible cards around existing legacy components. Also, many late-model ISA cards can be switched into PnP-compatible mode.

PnP adapter cards communicate with the system BIOS and the operating system to convey information about which system resources are necessary. The BIOS and operating system, in turn, resolve conflicts (wherever possible) and inform the adapter cards which specific resources it should use. The adapter card then can modify its configuration to use the specified resources.

The BIOS Component

The BIOS component means that most users of pre-1996 PCs need to update their BIOSes or purchase new machines that have PnP BIOSes. For a BIOS to be compatible, it must support 13 additional system function calls, which can be used by the OS component of a PnP system. The PnP BIOS specification was developed jointly by Compaq, Intel, and Phoenix Technologies.

The PnP features of the BIOS are implemented through an expanded POST. The BIOS is responsible for identification, isolation, and possible configuration of PnP adapter cards. The BIOS accomplishes these tasks by performing the following steps:

1. Disables any configurable devices on the motherboard or on adapter cards
2. Identifies any PnP PCI or ISA devices
3. Compiles an initial resource-allocation map for ports, IRQs, DMAs, and memory
4. Enables I/O devices
5. Scans the ROMs of ISA devices
6. Configures initial program-load (IPL) devices, which are used later to boot the system
7. Enables configurable devices by informing them which resources have been assigned to them
8. Starts the bootstrap loader
9. Transfers control to the operating system

The Operating System Component

The operating system component is found in most modern operating systems, such as Windows 9x/Me/2000/XP. In some cases system manufacturers have provided extensions to the operating system for their specific hardware. Such is especially true for notebook systems, for example. Be sure you load these extensions if they are required by your system.

It is the responsibility of the operating system to inform users of conflicts that cannot be resolved by the BIOS. Depending on the sophistication of the operating system, the user then could configure the offending cards manually (onscreen) or turn off the system and set switches on the physical cards. When the system is restarted, the system is checked for remaining (or new) conflicts, any of which are brought to the user's attention. Through this repetitive process, all system conflicts are resolved.

Note

Because of revisions in some of the Plug and Play specifications, especially including the ACPI specification, it can help to ensure you are running the latest BIOS and drivers for your system. With the Flash ROM used in most PnP systems, you can download the new BIOS image from the system vendor or manufacturer and run the supplied BIOS update program.

Knowing What to Look For (Selection Criteria)

I am often asked to make a recommendation for purchases. Without guidance, many individuals don't have any rhyme or reason to their selections and instead base their choices solely on magazine reviews or, even worse, on some personal bias. To help eliminate this haphazard selection process, I have developed a simple checklist that will help you select a system. This list takes into consideration several important system aspects overlooked by most checklists. The goal is to ensure that the selected system truly is compatible and has a long life of service and upgrades ahead.

It helps to think like an engineer when you make your selection. Consider every aspect and detail of the motherboards in question. For instance, you should consider any future uses and upgrades. Technical support at a professional (as opposed to a user) level is extremely important. What support will be provided? Is there documentation, and does it cover everything else?

In short, a checklist is a good idea. Here is one for you to use in evaluating any PC-compatible system. A system might not have to meet every one of these criteria for you to consider purchasing it, but if it misses more than a few, consider staying away from that system. The items at the top of the list are the most important, and the items at the bottom are perhaps of lesser importance (although I think each item is important). The rest of this chapter discusses in detail the criteria in this checklist:

- *Processor*. A modern system should use a socket-based processor with on-die L2 cache. Evaluate the processor choices you have, and try to get the one with the highest speed CPU bus (front-side bus). Don't get too hung up on L2 cache size; a little cache goes a long way. It is more important that the cache run at full core speed (which it will if it is on-die). Processors such as the later Celeron/Pentium III, Duron/Athlon, and Pentium 4 all meet this criteria.
- *Processor sockets*. For maximum upgradability and performance, you should stick with a system that uses a socket for the CPU. The main sockets in use today are Socket 370 for the Celeron/Pentium III, Socket A (Socket 462) for the Duron/Athlon, and Socket 423 for the Pentium 4. As long as your motherboard has one of these sockets, you should be in good shape.
- *Motherboard speed*. The motherboard typically offers a choice of speeds, including anywhere from 66MHz to 266MHz for Celeron/Pentium III–based boards, 200MHZ–266MHz for the Duron/Athlon-based boards, or 400MHz for the Pentium 4–based boards. Check to ensure the board you are buying runs at the speeds necessary to support the processors you want to install.
- *Cache memory*. All modern systems use processors with integral cache, most of them now having the cache directly on the processor die for maximum speed. As such, there won't be any cache memory on the motherboard in a modern system. The tip is to make sure you are using a processor with full core speed on-die L2 cache because this offers the maximum in performance. All the modern processors now incorporate on-die L2 cache.
- *SIMM/DIMM/RIMM memory*. SIMMs are obsolete by today's standards, so stay away from any boards that use them. Your board should support either standard or DDR DIMMs or RIMMs that contain SDRAM, DDR SDRAM, or RDRAM, respectively. What you use depends mainly on your motherboard chipset, so choose the chipset and board that accepts the memory type you want to use. Currently, DDR SDRAM and RDRAM are the fastest types of memory available, with RDRAM being by far the most costly.

Mission-critical systems should use ECC memory and ensure that the motherboard fully supports ECC operation. Note that many of the low-end chipsets, such as the Intel 810/815 series, do not support ECC and should not be used for mission-critical applications. This is something you should know before purchasing the system.

Finally, note that most motherboards support either three or four DIMM sockets, or two or three RIMM sockets. Be sure that you populate them wisely so you don't have to resort to removing memory later to add more, which is not very cost-effective.

- *Bus type*. Most motherboards no longer incorporate ISA bus slots, so if you have any ISA cards, you'll likely have to discard them. Instead you should find anywhere from one to five or more PCI local bus slots. Be sure the PCI slots conform to the PCI 2.1 or later revision (primarily based on the chipset). Take a look at the layout of the slots to ensure that cards inserted in them will not block access to memory sockets or be blocked by other components in the case. Systems without onboard video should also feature one AGP 4x slot for a high-performance AGP video card.
- *BIOS*. The motherboard should use an industry-standard BIOS, such as those from AMI, Phoenix, or Award. The BIOS should be of a Flash ROM or EEPROM design for easy updating. Look for a BIOS Recover jumper or mode setting, as well as possibly a Flash ROM write-protect jumper on some systems.
- *Form factor*. For maximum flexibility, performance, reliability, and ease-of-use, the ATX form factor (including micro-ATX and flex-ATX) cannot be beat. ATX has several distinct performance and functional advantages over Baby-AT and is vastly superior to any proprietary designs, such as LPX. Additionally, the new NLX form factor might be a consideration for low-profile or low-cost desktop systems.
- *Built-in interfaces*. Ideally, a motherboard should contain as many built-in standard controllers and interfaces as possible (except perhaps video). There is a trend toward legacy-free PCs that lack the conventional Super I/O component and therefore have only USB for external expansion. Legacy-free PCs lack the conventional keyboard and mouse ports, serial and parallel ports, and possibly even the internal floppy controller. Systems that use an integrated Super I/O component have these interfaces.

  Built-in 10/100 Ethernet network adapters are also handy, especially if you are using a cable modem or DSL connection to the Internet. A built-in sound card is a great feature, usually offering full Sound Blaster compatibility and functions, and possibly offering additional features as well. If your sound needs are more demanding, you might find the built-in solutions less desirable, and you might want to have a separate sound card in your system. Built-in video adapters are also a bonus in some situations, but because there are many video chipset and adapter designs from which to choose, generally you'll find better choices in external local bus video adapters. This is especially true if you need the highest performance video available.

  Built-in devices usually can be disabled to allow future add-ons, but problems can result.
- *Onboard IDE interfaces*. All motherboards on the market have included onboard IDE interfaces for some time now, but not all IDE interfaces are equal. Your motherboard should support at least UDMA/33 (ATA-33) speeds, which matches the best real-world performance currently available from IDE drives. UDMA/66 and UDMA/100 actually exceed the real-world performance of current drives using these standards and thus provide you with headroom for future drives. For even greater speed, consider motherboards with onboard IDE RAID controllers. These motherboards can be configured to perform data striping for extra speed or data mirroring for extra reliability when two or more identical IDE drives are used. These motherboards are based on a variety of standard chipsets with RAID functions added by RAID chipsets from AMI, HighPoint, or Promise.

Tip

With a never-ending stream of motherboards coming onto the market, finding motherboards with the features you want can be difficult. Motherboard Homeworld's Mobot search engine helps you find motherboards based on your choice of form factor, platform, chipset, CPU type, processor, manufacturer, memory type, slot types, built-on ports, and more. Check it out at

`<http://iceberg.pchomeworld.com/cgi-win/mobotGen/mobot.asp>`

- *Power management*. The motherboard should fully support the latest standard for power management, which is ACPI. An Energy Star–compliant system is also a bonus because it uses less than 30 watts of electrical energy when in sleep mode, saving energy as well as your electric bill.
- *Motherboard chipset*. Motherboards should use a high-performance chipset that supports standard or DDR SDRAM DIMMs or RDRAM RIMMs—preferably one that allows ECC memory as well, if you are concerned about catching possible memory errors before they corrupt your data. Also look for AGP 4x or faster video support and ATA-100 hard drive support.
- *Documentation*. Good technical documentation is a requirement. Documents should include information on any and all jumpers and switches found on the board, connector pinouts for all connectors, specifications for other plug-in components, and any other applicable technical information. I would also acquire separate documentation from the BIOS manufacturer covering the specific BIOS used in the system, as well as the data books covering the specific chipset used in the motherboard. Additional data books for any other controller or I/O chips onboard are a bonus and can be acquired from the respective chip manufacturers.

  Another nice thing to have is available online support and documentation updates, although this should not be accepted in place of good hardcopy manuals. Remember that many vendors provide their "hardcopy" manuals as Adobe Acrobat files, which can be viewed and printed with the Adobe Acrobat Reader program.

You might notice that these selection criteria seem fairly strict and might disqualify many motherboards on the market, including what you already have in your system! These criteria will, however, guarantee you the highest-quality motherboard offering the latest in PC technology that will be upgradable, be expandable, and provide good service for many years.

Most of the time I recommend purchasing boards from better-known motherboard manufacturers such as Intel, Acer, ABIT, AsusTek, SuperMicro, Tyan, and others. These boards might cost a little more, but there is some safety in the more well-known brands. That is, the more boards they sell, the more likely that any problems will have been discovered by others and solved long before you get yours. Also, if service or support is necessary, the larger vendors are more likely to be around in the long run.

Documentation

As mentioned, extensive documentation is an important factor to consider when you're planning to purchase a motherboard. Most motherboard manufacturers design their boards around a particular chipset, which actually counts as the bulk of the motherboard circuitry. A number of manufacturers offer chipsets, such as Intel, VIA, ALi, SiS, and others. I recommend obtaining the data book or other technical documentation on the chipset directly from the chipset manufacturer.

One of the more common questions I hear about a system relates to the BIOS Setup program. People want to know what the "Advanced Chipset Setup" features mean and what the effects of changing them will be. Often they go to the BIOS manufacturer thinking that the BIOS documentation will offer help. Usually, however, people find that there is no real coverage of what the chipset setup features are in the BIOS documentation. You will find this information in the data book provided by the chipset manufacturer. Although these books are meant to be read by the engineers who design the boards, they contain all the detailed information about the chipset's features, especially those that might be adjustable. With the chipset data book, you will have an explanation of all the controls in the Advanced Chipset Setup section of the BIOS Setup program.

Besides the main chipset data books, I also recommend collecting any data books on the other major chips in the system. This would include any floppy or IDE controller chips, Super I/O chips, and of course the main processor. You will find an incredible amount of information on these components in the data books.

Caution

Most chipset manufacturers make a particular chip for only a short time, rapidly superseding it with an improved or changed version. The data books are available only during the time the chip is being manufactured, so if you wait too long, you will find that such documents might no longer be available. The time to collect documentation on your motherboard is *now*!

Using Correct Speed-Rated Parts

Some vendors use substandard parts in their systems to save money. Because the CPU is one of the most expensive components on the motherboard, and motherboards are sold to system assemblers without the CPU installed, it is tempting for the assembler to install a CPU rated for less than the actual operating speed. A system could be sold as a900MHz system, for example, but when you look under the hood, you might find a CPU rated for only 600MHz. This is called *overclocking*, and many vendors have practiced this over the last few years. Some even go so far as to re-mark the CPUs, so that even if you look, the part appears to have the correct rating. The best way to stop that is to purchase systems from known, reliable vendors and purchase processors from distributors that are closely connected with the manufacturer. Overclocking is fine if you want to do it yourself and understand the risks, but when I purchase a new system, I expect that all the parts included be rated to run at the speed they are set to.

◀◀ See "Processor Speed Ratings," p. 47.

When a chip is run at a speed higher than it is rated for, it runs hotter than it would normally. This can cause the chip to overheat occasionally, which would appear as random lockups, glitches, and frustration. I highly recommend that you check to ensure you are getting the right speed-rated parts you are paying for.

Also be sure you use the recommended heatsink compound (thermal grease). This can improve the efficiency of your heatsink by up to 30%.

This practice is easy to fall into because the faster-rated chips cost more money. Intel and other chip manufacturers usually rate their chips very conservatively. Over the years, I have overclocked many processors, running them sometimes well beyond their rated speeds. Although I might purchase a Pentium III 800 and run it at 1066MHz, if I were to experience lockups or glitches in operation, I would immediately return it to the original speed and retest. If I purchase a 1GHz system from a vendor, I fully expect it to have a 1GHz part, not slower parts running past their rated speeds!

Overclocking has been made more difficult by Intel and AMD, who have both started locking the bus multipliers in their chips to prevent easy overclocking by changing the multiplier setting on the motherboard. This is done mainly to combat re-marking CPUs and deceiving customers, although unfortunately it also can prevent those who want to from hotrodding their chips. Still, you can overclock most chips by increasing the CPU bus (front-side bus) speed within certain tolerances. Many of the motherboards on the market have tweakable CPU bus speeds specifically designed to allow overclocking. Check with your motherboard manual, or download the documentation from the manufacturer's Web site. You might find that your board is capable of things you didn't realize.

If you purchase a processor or a system, verify that the markings are the original Intel or AMD markings and that the speed rating on the chip is what you really paid for.

The bottom line: If the price is too good to be true, ask before you buy. Are the parts really manufacturer-rated for the system speed?

To determine the rated speed of a CPU chip, look at the writing on the chip. See Chapter 3 for details on how to interpret the marks to see what the real rating on the chip actually is.

Caution

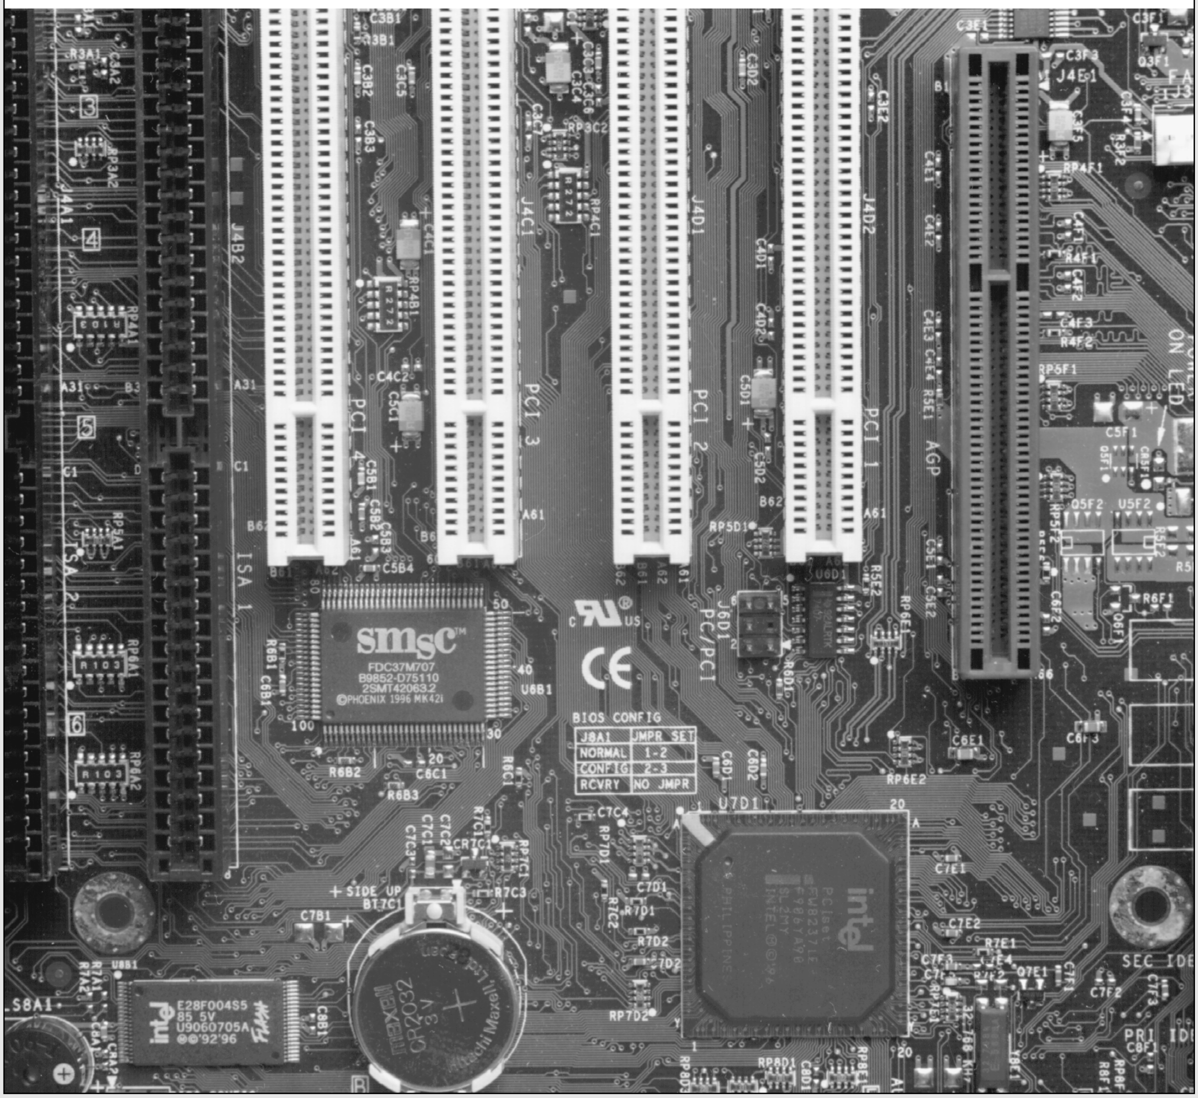
Be careful when running software to detect processor speed. Most programs can only estimate what speed the chip is currently running at, not what the true original rating is. One exception to this is the Intel Processor Frequency ID Utility, which can determine whether an Intel processor is operating at the correct and rated frequency intended. Although it gives only basic information about any Intel processor, it can uniquely identify the original speed ratings of the Pentium III, third-generation Celeron (Coppermine-based), and any newer processors, accurately determining whether they have been overclocked. You can download the Intel Processor Frequency ID Utility from `http://developer.intel.com/support/processors/tools/frequencyid/download.htm`.

Older system chassis with speed markings or even indicator lights are usually no indication of the actual or rated speed of the processor inside. Those displays can literally be set via jumpers to read any speed you desire! They have no true relation to actual system speed.

Most of the better diagnostics on the market, such as the Norton Utilities from Symantec, read the processor ID and stepping information, as well as show current operating (but not rated) speed. You can consult the processor manufacturer or Chapter 3 for tables listing the various processor steppings to see exactly how yours stacks up.

CHAPTER 5

BIOS



BIOS Basics

It is often difficult for people to understand the difference between hardware and software in a PC system. The differences can be difficult because they are both very much intertwined in the system design, construction, and operation. Understanding these differences is essential to understanding the role of the BIOS in the system.

BIOS is a term that stands for *basic input/output system*. BIOS is really the link between hardware and software in a system. Most people know the term BIOS by another name—*device drivers*, or just *drivers*.

BIOS is a single term that describes all the drivers in a system working together to act as an interface between the hardware and the operating system software. What can be confusing is that some of the BIOS is burned or flashed into a ROM chip that is both nonvolatile (it doesn't get erased when the power is turned off) and read-only. This is a core part of the BIOS, but not all of it. The BIOS also includes ROM chips installed on adapter cards, as well as all the additional drivers loaded when your system boots up.

The combination of the motherboard BIOS, the adapter card BIOS, and the device drivers loaded from disk contribute to the BIOS as a whole. The portion of the BIOS contained in ROM chips both on the motherboard and in some adapter cards is sometimes called *firmware*, which is a name given to software stored in chips rather than on disk. This causes some people to incorrectly think of the BIOS as a hardware component.

A PC system can be described as a series of layers—some hardware and some software—that interface with each other. In the most basic sense, you can break a PC down into four primary layers, each of which can be broken down further into subsets. Figure 5.1 shows the four layers in a typical PC.

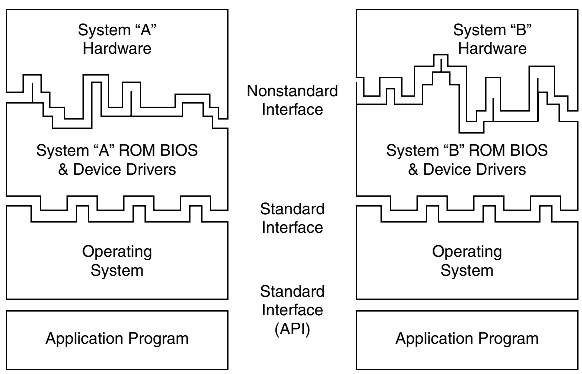


Figure 5.1 PC system layers.

The purpose of the layered design is to enable a given operating system and applications to run on different hardware. Figure 5.1 shows how two different machines with different hardware can each use a custom BIOS to interface the unique hardware to a common operating system and applications. Thus, two machines with different processors, storage media, video display units, and so on can run the same software.

In this layered architecture, the application programs talk to the operating system via what is called an Application Program Interface (API). The API varies according to the operating system you are using and consists of the various commands and functions the operating system can perform for an application. For example, an application can call on the operating system to load or save a file. This prevents the application itself from having to know how to read the disk, send data to a printer, or perform any other of the many functions the operating system can provide. Because the application is completely insulated from the hardware, you can essentially run the same applications on different systems; the application is designed to talk to the operating system rather than the hardware.

The operating system then interfaces with or talks to the BIOS layer. The BIOS consists of all the individual driver programs that operate between the operating system and the actual hardware. As such, the operating system never talks to the hardware directly; instead, it must always go through the appropriate driver. This provides a consistent way to talk to the hardware. It is usually the responsibility of the hardware manufacturer to provide drivers for its hardware. Because the drivers must act between both the hardware and the operating system, the drivers typically are operating system specific. Thus, the hardware manufacturer must offer different drivers so that its hardware works under DOS, Windows 9x, Windows NT, Windows 2000, OS/2, Linux, and so on.

Because the BIOS layer looks the same to the operating system no matter what hardware is above it (or underneath, depending on your point of view), you can have the same operating system running on a variety of PCs. For example, you can run Windows 98 on two systems with different processors, hard disks, video adapters, and so on, yet Windows 98 will look and feel pretty much the same on both of them. This is because the drivers provide the same basic functions no matter which specific hardware is used.

As you can see from Figure 5.1, the application and operating systems layers can be identical from system to system, but the hardware can differ radically. Because the BIOS consists of software drivers that act to interface the hardware to the software, the BIOS layer adapts to the unique hardware on one end but looks consistently the same to the operating system at the other end.

The hardware layer is where most differences lie between various systems. It is up to the BIOS to mask the differences between unique hardware so that the given operating system (and subsequently the application) can be run. This chapter focuses on the BIOS layer of the PC.

BIOS Hardware/Software

The BIOS itself is software running in memory that consists of all the various drivers that interface the hardware to the operating system. The BIOS is unique compared to normal software in that it doesn't all load from disk; some of it is preloaded into memory chips (read-only memory, or ROM) installed in the system or on adapter cards.

The BIOS in a PC comes from three possible sources:

- Motherboard ROM
- Adapter card ROM (such as that found on a video card)
- Loaded into RAM from disk (device drivers)

The motherboard ROM BIOS is most often associated with hardware rather than software. This is because the BIOS on the motherboard is contained in a ROM chip on the board, which contains the initial software drivers needed to get the system running. Years ago, when running only DOS on basic PCs, this was enough so that no other drivers were needed; the motherboard BIOS had everything that was necessary. The motherboard BIOS usually includes drivers for all the basic system components, including the keyboard, floppy drive, hard drive, serial and parallel ports, and more. As systems became more complex, new hardware was added for which no motherboard BIOS drivers existed. These included devices such as newer video adapters, CD-ROM drives, SCSI hard disks, USB ports, and so on.

Rather than requiring a new motherboard BIOS that would specifically support the new devices, it was far simpler and more practical to copy any new drivers that were necessary onto the system hard disk and configure the operating system to load them at boot time. This is how most CD-ROM drives, sound cards, scanners, printers, PC-card (PCMCIA) devices, and so on are supported. Because these devices don't need to be active during boot time, the system can boot up from the hard disk and wait to load the drivers during the initial operating system load.

Some drivers, however, must be active during boot time. For example, how could you boot from a hard disk if the drivers necessary to make the disk interface work must be loaded from that disk? Obviously, the hard disk drivers must be preloaded into ROM either on the motherboard or on an adapter card.

How will you be able to see anything onscreen if your video card doesn't have a set of drivers in a ROM? The solution to this could be to provide a motherboard ROM with the appropriate video drivers built in; however, this is impractical because of the variety of cards, each needing its own drivers. You would end up with hundreds of different motherboard ROMs, depending on which video card you had. Instead, when IBM designed the original PC, it created a better solution. It designed the PC's motherboard ROM to scan the slots looking for adapter cards with ROMs on them. If a card was found with a ROM on it, the ROM was executed during the initial system startup phase, before the system began loading the operating system from the hard disk.

By putting the ROM-based drivers right on the card, you didn't have to change your motherboard ROM to have built-in support for new devices, especially those that needed to be active during boot time. A few cards (adapter boards) almost always have a ROM onboard, including the following:

- *Video cards*. All have an onboard BIOS.
- *SCSI adapters*. Those that support booting from SCSI hard drives or CD-ROMs have an onboard BIOS. Note that, in most cases, the SCSI BIOS does not support any SCSI devices other than a hard disk; if you use a SCSI CD-ROM, scanner, Zip drive, and so on, you still need to load the appropriate drivers for those devices from your hard disk. Most newer SCSI adapters support booting from a SCSI CD-ROM, but CD-ROM drivers are still necessary to access the CD-ROM when booting from another drive or device.
- *Network cards*. Those that support booting directly from a file server have what is usually called a boot ROM or IPL (initial program load) ROM onboard. This enables PCs to be configured on a LAN as diskless workstations—also called Net PCs, NCs (network computers), or even smart terminals.
- *IDE or floppy upgrade boards*. Boards that enable you to attach more or different types of drives than what is normally supported by the motherboard alone. These cards require an onboard BIOS to enable these drives to be bootable.
- *Y2K boards*. Boards that incorporate BIOS fixes to update the century byte in the CMOS RAM. These boards have a small driver contained in a BIOS, which monitors the year byte for a change from 99 to 00. When this is detected, the driver updates the century byte from 19 to 20, correcting a flaw in some older motherboard BIOSes. Although it might seem strange to list Y2K boards, these will still be in use until the systems using them are retired.

BIOS and CMOS RAM

Some people confuse BIOS with the CMOS RAM in a system. This confusion is aided by the fact that the Setup program in the BIOS is used to set and store the configuration settings in the CMOS RAM. They are, in fact, two totally separate components.

The BIOS on the motherboard is stored in a fixed ROM chip. Also on the motherboard is a chip called the RTC/NVRAM chip, which stands for real-time clock/nonvolatile memory. This is actually a digital clock chip with a few extra bytes of memory thrown in.

The first one ever used in a PC was the Motorola MC146818 chip, which had 64 bytes of storage, of which 10 bytes were dedicated to the clock function. Although it is called nonvolatile, it is actually volatile, meaning that without power, the time/date settings and the data in the RAM portion will, in fact, be erased. It is called nonvolatile because it is designed using complementary metal-oxide semiconductor (CMOS) technology, which results in a chip that runs on very little power. A battery in the system, rather than the AC wall current, provides that power. This is also why most people incorrectly call this chip the CMOS RAM chip; although not technically accurate, that is easier to say than the RTC/NVRAM chip. Most RTC/NVRAM chips run on as little as one microamp (millionth of an amp), so they use very little battery power to run. Most last five years before the lithium battery runs out and the information stored gets erased. Some systems use a Dallas Semiconductor RTC/NVRAM chip (such as the DS12885 and DS12887) that also contain the battery.

When you enter your BIOS Setup, configure your hard disk parameters or other BIOS Setup settings and save them, these settings are written to the storage area in the RTC/NVRAM (otherwise called CMOS RAM) chip. Every time your system boots up, it reads the parameters stored in the CMOS RAM chip to determine how the system should be configured. A relationship exists between the BIOS and CMOS RAM, but they are two distinctly different parts of the system.

Motherboard BIOS

All motherboards must have a special chip containing software called the ROM BIOS. This ROM chip contains the startup programs and drivers used to get the system running and act as the interface to the basic hardware in the system. When you turn on a system, the power on self test (POST) in the BIOS also tests the major components in the system. Additionally, you can run a setup program to store system configuration data in the CMOS memory, which is powered by a battery on the motherboard. This CMOS RAM is often called NVRAM (nonvolatile RAM) because it runs on about one millionth of an amp of electrical current and can store data for years when powered by a tiny lithium battery.

▶▶ See “ROM Hardware,” p. 350.

The BIOS is a collection of programs embedded in one or more chips, depending on the design of your computer. That collection of programs is the first thing loaded when you start your computer, even before the operating system. Simply put, the BIOS in most PCs has four main functions:

- *POST (power on self test)*. The POST tests your computer’s processor, memory, chipset, video adapter, disk controllers, disk drives, keyboard, and other crucial components.
- *Setup*. System configuration and setup program. This is usually a menu-driven program activated by pressing a special key during the POST, which enables you to configure the motherboard and chipset settings along with the date and time, passwords, disk drives, and other basic system settings. You also can control the power-management settings and boot-drive sequence from the BIOS Setup, and on some systems, you can also configure CPU timing and clock-multiplier settings. Some older 286 and 386 systems did not have the Setup program in ROM and required that you boot from a special setup disk.
- *Bootstrap loader*. A routine that reads the disk drives looking for a valid master boot sector. If one meeting certain minimum criteria (ending in the signature bytes 55AAh) is found, the code within is executed. This master boot sector program then continues the boot process by loading an operating system boot sector, which then loads the operating system core files.
- *BIOS (basic input/output system)*. This refers to the collection of actual drivers used to act as a basic interface between the operating system and your hardware when the system is booted and running. When running DOS or Windows in safe mode, you are running almost solely on ROM-based BIOS drivers because none are loaded from disk.

ROM Hardware

Read-only memory (ROM) is a type of memory that can permanently or semipermanently hold data. It is called read-only because it is either impossible or difficult to write to. ROM is also often called nonvolatile memory because any data stored in ROM remains even if the power is turned off. As such, ROM is an ideal place to put the PC's startup instructions—that is, the software that boots the system (the BIOS).

Note that ROM and RAM are not opposites, as some people seem to believe. In fact, ROM is technically a subset of the system's RAM. In other words, a portion of the system's random access memory address space is mapped into one or more ROM chips. This is necessary to contain the software that enables the PC to boot up; otherwise, the processor would have no program in memory to execute when it is powered on.

For example, when a PC is turned on, the processor automatically jumps to address FFFF0h, expecting to find instructions to tell the processor what to do. This location is exactly 16 bytes from the end of the first megabyte of RAM space, as well as the end of the ROM itself. If this location were mapped into regular RAM chips, any data stored there would have disappeared when the power was previously turned off, and the processor would subsequently find no instructions to run the next time the power was turned on. By placing a ROM chip at this address, a system startup program can be permanently loaded into the ROM and will be available every time the system is turned on.

▶▶ For more information about Dynamic RAM, see "DRAM," p. 407.

Normally, the system ROM starts at address E0000h or F0000h, which is 128KB or 64KB prior to the end of the first megabyte. Because the ROM chip usually is up to 128KB in size, the ROM programs are allowed to occupy the entire last 128KB of the first megabyte, including the critical FFFF0h startup instruction address, which is located 16 bytes from the end of the BIOS space. Some motherboard ROM chips are larger, up to 256KB or 512KB in size. The additional code in these is configured to act as a video card ROM (addresses C0000h–C7FFFh) on motherboards with built-in video and might even contain additional ROM drivers configured anywhere from C8000h to DFFFFh to support additional onboard devices, such as SCSI or network adapters.

Figure 5.2 shows a map of the first megabyte of memory in a PC, showing the upper memory areas reserved for adapter card and motherboard ROM BIOS at the end of the first megabyte.

Some think it is strange that the PC would start executing BIOS instructions 16 bytes from the end of the ROM, but this design was intentional. All the ROM programmer has to do is place a JMP (jump) instruction at that address that instructs the processor to jump to the actual beginning of the ROM—in most cases, close to F0000h—which is about 64KB earlier in the memory map. It's like deciding to read every book starting 16 pages from the end and then having all book publishers agree to place an instruction there to jump back the necessary number of pages to get to page 1. By setting the startup location in this way, Intel enabled the ROM to grow to be any size, all the while keeping it at the upper end of addresses in the first megabyte of the memory address space.

The main ROM BIOS is contained in a ROM chip on the motherboard, but adapter cards with ROMs contain auxiliary BIOS routines and drivers needed by the particular card, especially for those cards that must be active early in the boot process, such as video cards. Cards that don't need drivers active during boot (such as sound cards) typically don't have a ROM because those drivers can be loaded from the hard disk later in the boot process.

Because the BIOS is the main portion of the code stored in ROM, we often call the ROM the ROM BIOS. In older PCs, the motherboard ROM BIOS could consist of up to five or six total chips, but most PCs have required only a single chip for many years now.

Figure 5.2 PC memory map showing ROM BIOS.

Adapter card ROMs, such as those used for video, SCSI, add-on IDE cards, and network cards for diskless workstations, are automatically scanned and read by the motherboard ROM during the early part of the boot process, during the POST. The motherboard ROM scans a special area of RAM reserved for adapter ROMs (addresses C0000–DFFFFh) looking for a 55AAh signature byte pair that indicates the start of a ROM.

All adapter ROMs must start with 55AAh; otherwise, the motherboard won't recognize them. The third byte indicates the size of the ROM in 512-byte units called *paragraphs*, and the fourth byte is the actual start of the driver programs. The size byte is used by the motherboard ROM for testing purposes. The motherboard ROM adds all the bytes in the ROM and divides the sum by the number of bytes. The result should produce a remainder of 100h. Thus, when creating a ROM for an adapter, the programmer normally uses a "fill" byte at the end to get the checksum to come out right. Using this checksum the motherboard tests each adapter ROM during the POST and flags any that appear to have been corrupted.

The motherboard BIOS automatically runs the programs in any adapter ROMs it finds during the scan. You see this in most systems when you turn on your system, and during the POST you see the video card BIOS initialize and announce its presence.

ROM Shadowing

ROM chips by their natures are very slow, with access times of 150ns (nanoseconds, or billionths of a second), compared to DRAM access times of less than 10ns on the newest systems. Because of this, in virtually all systems the ROMs are *shadowed*, which means they are copied into DRAM chips at startup to allow faster access during normal operation. The shadowing procedure copies the ROM into RAM and then assigns that RAM the same address as the ROM originally used, disabling the actual ROM in the process. This makes the system seem as though it has ROM running at the same speed as RAM.

The performance gain from shadowing is often very slight, and it can cause problems if not set up properly. Therefore, in most cases, it is wise to shadow only the motherboard and maybe the video card BIOS and leave the others alone.

Mostly, shadowing is useful only if you are running 16-bit operating systems, such as DOS or Windows 3.x. If you are running a 32-bit operating system, such as Windows 9x, Windows Me, Windows 2000, Windows NT, or Windows XP, shadowing is virtually useless because those operating systems do not use the 16-bit ROM code while running. Instead, those operating systems load 32-bit drivers into RAM, which replace the 16-bit BIOS code used only during system startup.

Shadowing controls are found in the CMOS Setup program in the motherboard ROM, which is covered in more detail later in this chapter.

The four types of ROM chips are as follows:

- *ROM.* Read-only memory
- *PROM.* Programmable ROM
- *EPROM.* Erasable PROM
- *EEPROM.* Electrically erasable PROM, also called flash ROM

No matter which type of ROM your system uses, the data stored in a ROM chip is nonvolatile and remains indefinitely unless intentionally erased or overwritten (in those cases where that is possible).

Table 5.1 lists the identifying part numbers typically used for each type of ROM chip, along with any other identifying information.

Table 5.1 ROM Chip Part Numbers

ROM Type	Part Number	Other
ROM	No longer in use	
PROM	27nnnn	
EPROM	27nnnn	Quartz Window
EEPROM	28xxxx or 29xxxx	

ROM (True or Mask ROM)

Originally, most ROMs were manufactured with the binary data (0s and 1s) already “cast in” or integrated into the die. The die represents the actual silicon chip itself. These are called Mask ROMs because the data is formed into the mask from which the ROM die is photolithographically produced. This type of manufacturing method is economical if you are making hundreds of thousands of ROMs with the same information. If you must change a single bit, however, you must remake the mask, which is an expensive proposition. Because of costs and inflexibility, nobody uses Mask ROMs anymore.

Mask ROMs are exactly analogous to prerecorded CD-ROMs. Some people think a CD-ROM is first manufactured as a blank and then the data is written to it by laser, but that is not true. A CD-ROM is literally a piece of plastic that is stamped in a press, and the data is directly molded in, not written. The only actual recording is done with the master disc from which the molds or stamps are made.

PROM

PROMs are a type of ROM that is blank when new and that must be programmed with whatever data you want. The PROM was invented in the late 1970s by Texas Instruments and has been available in sizes from 1KB (8Kb) to 2MB (16Mb) or more. They can be identified by their part numbers, which usually are 27nnnn—where the 27 indicates the TI type PROM, and the nnnn indicates the size of the chip in kilobits (not bytes). For example, most PCs that used PROMs came with 27512 or 271000 chips, which indicate 512Kb (64KB) or 1Mb (128KB).

Note

Since 1981, all cars sold in the U.S. have used onboard computers with some form of ROM containing the control software. My 1989 Pontiac Turbo Trans Am came with an onboard computer containing a 2732 PROM, which was a 32Kb (4KB) chip in the ECM (electronic control module or vehicle computer) under the dash. This chip contained a portion of the vehicle operating software as well as all the data tables describing spark advance, fuel delivery, and other engine and vehicle operating parameters. Many devices with integrated computers use PROMs to store their operating programs.

Although we say these chips are blank when new, they are technically preloaded with binary 1s. In other words, a 1Mb ROM chip used in a modern PC would come with one million (actually 1,048,576) bit locations, each containing a binary 1. A blank PROM can then be programmed, which is the act of writing to it. This usually requires a special machine called a device programmer, a ROM programmer, or a ROM burner (see Figure 5.3).

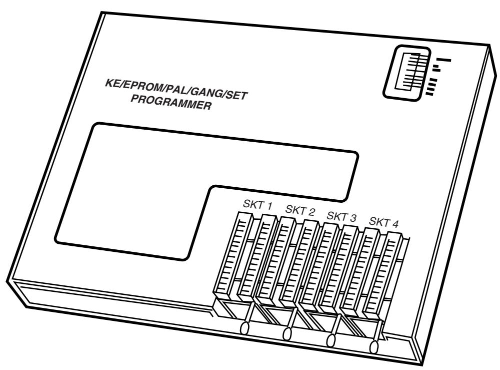

Figure 5.3 Typical gang (multisocket) device programmer (PROM burner).

Programming the ROM is sometimes referred to as *burning* it because that is technically an apt description of the process. Each binary 1 bit can be thought of as a fuse, which is intact. Most chips run on 5 volts, but when a PROM is programmed, a higher voltage (normally 12 volts) is placed at the various addresses within the chip. This higher voltage actually blows or burns the fuses at the desired locations, thus turning any given 1 into a 0. Although you can turn a 1 into a 0, you should note that the process is irreversible; that is, you can't turn a 0 back into a 1.

The device programmer examines the program you want to write into the chip and then selectively changes only the 1s to 0s where necessary in the chip.

PROM chips are often referred to as OTP (one-time programmable) chips for this reason. They can be programmed once and never erased. Most PROMs are very inexpensive—about $3 for a typical PC motherboard PROM—so if you want to change the program in a PROM, you discard it and program a fresh one with the new data.

The act of programming a PROM takes anywhere from a few seconds to a few minutes, depending on the size of the chip and the algorithm used by the programming device. Figure 5.3 shows an illustration of a typical PROM programmer that has multiple sockets. This is called a *gang programmer* and can program several chips at once, saving time if you have several chips to write with the same data. Less expensive programmers are available with only one socket, which is fine for most individual use.

I use and recommend a very inexpensive programmer from a company called Andromeda Research (see the vendor list on the CD). Besides being economical, its unit has the advantage of connecting to a PC via the parallel port for fast and easy data transfer of files between the PC and the programming unit. The unit is also portable and comes built into a convenient carrying case. It is operated by an included menu-driven program you install on the connected PC. The program contains several features, including a function that enables you to read the data from a chip and save it in a file on your system, as well as to write a chip from a data file, verify that a chip matches a file, and verify that a chip is blank before programming begins. A low-cost BIOS backup option makes backing up the flash BIOS chip in your system easy (if it is removable) as a safeguard against disaster.

Chapter 4, "Motherboards and Buses," shows how I used my PROM programmer to modify the BIOS in some of my older PCs. With today's systems primarily using flash ROMs, this capability is somewhat limited, but I include the information because I think it is interesting.

Note

I even used my PROM programmer to reprogram the PROM in my 1989 Turbo Trans Am, changing the factory preset speed and rpm limiters, turbocharger boost, torque converter lockup points, spark advance, fuel delivery, idle speed, and much more! I also incorporated a switch box under the dash that enables me to switch among four different chips, even while the vehicle is running. One chip I created I call the "valet chip," which, when engaged, cuts off the fuel injectors at a preset speed of 36 miles per hour and restarts them when the vehicle coasts down to 35mph. I imagine this type of modification would be useful for those with teenage drivers because you could set the mph or engine rpm limit to whatever you want! Another chip I created cuts off fuel to the engine altogether, which I engage for security purposes when the vehicle is parked. No matter how clever, a thief will not be able to steal this car unless he tows it away. If you are interested in such a chip-switching device or custom chips for your Turbo Trans Am or Buick Grand National, contact Casper's Electronics (see the Vendor List on the CD-ROM accompanying this book). For other vehicles with replaceable PROMs, companies such as Superchips, Hypertech, or Evergreen offer custom PROMs for improved performance (see the Vendor List on the CD). I installed a Superchips chip in a Ford Explorer I had, and it made a dramatic improvement in engine operation and vehicle performance.

EPROM

One variation of the PROM that has been very popular is the EPROM. An *EPROM* is a PROM that is erasable. An EPROM chip can be easily recognized by the clear quartz crystal window set in the chip package directly over the die (see Figure 5.4). You can actually see the die through the window! EPROMs have the same 27xxxx part-numbering scheme as the standard PROM, and they are functionally and physically identical except for the clear quartz window above the die.

The purpose of the window is to allow ultraviolet light to reach the chip die because the EPROM is erased by exposure to intense UV light. The window is quartz crystal because regular glass blocks UV light. You can't get a suntan through a glass window!

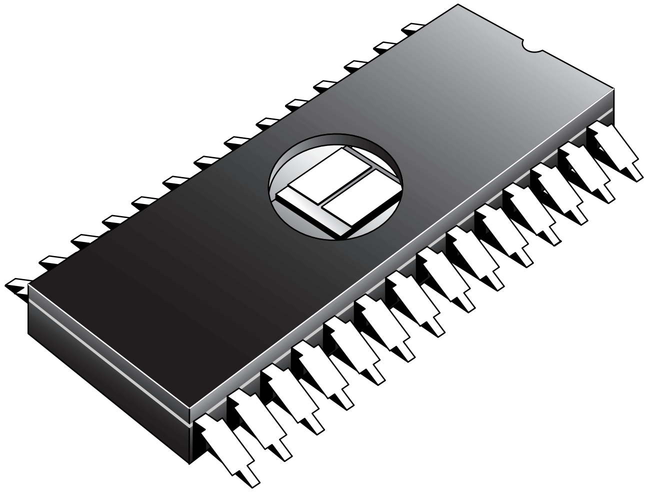

Figure 5.4 An EPROM showing the quartz window for ultraviolet erasing.

Note

The quartz window makes the EPROMs more expensive than the OTP PROMs. This extra expense is needless if erasability is not important.

The UV light erases the chip by causing a chemical reaction, which essentially melts the fuses back together! Thus, any binary 0s in the chip become 1s, and the chip is restored to a new condition with binary 1s in all locations. To work, the UV exposure must be at a specific wavelength (2,537 angstroms), at a fairly high intensity (12,000 uw/cm^2), in close proximity (2cm–3cm, or about 1 inch), and last for between 5 and 15 minutes duration. An EPROM eraser (see Figure 5.5) is a device that contains a UV light source (usually a sunlamp-type bulb) above a sealed compartment drawer in which you place the chip or chips.

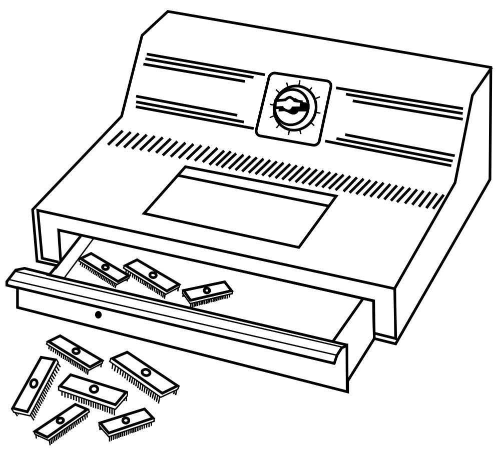

Figure 5.5 A professional EPROM eraser.

Figure 5.5 shows a professional-type EPROM eraser that can handle up to 50 chips at a time. I use a much smaller and less expensive one called the DataRase by Walling Co. This device erases up to four chips at a time and is both economical and portable. The current version is called DataRase II; the DataRase II and similar products are sold by many vendors of EPROM programming equipment.

The quartz crystal window on an EPROM typically is covered by tape, which prevents accidental exposure to UV light. UV light is present in sunlight, of course, and even in standard room lighting, so that over time a chip exposed to the light can begin to degrade. For this reason, after a chip is programmed, you should put a sticker over the window to protect it.

EEPROM/Flash ROM

A newer type of ROM is the *EEPROM*, which stands for electrically erasable PROM. These chips are also called flash ROMs and are characterized by their capability to be erased and reprogrammed directly in the circuit board they are installed in, with no special equipment required. By using an EEPROM, or flash ROM, you can erase and reprogram the motherboard ROM in a PC without removing the chip from the system or even opening up the system chassis!

With a flash ROM or EEPROM, you don't need a UV eraser or device programmer to program or erase chips. Not only do virtually all PC motherboards built since 1994 use flash ROMs or EEPROMs, most automobiles built since then also use them as well. For example, my 1994 Chevy Impala SS has a PCM (powertrain control module) with an integral flash ROM.

The EEPROM or flash ROM can be identified by a 28xxxx or 29xxxx part number, as well as by the absence of a window on the chip. Having an EEPROM or a flash ROM in your PC motherboard means you now can easily upgrade the motherboard ROM without having to swap chips. In most cases, you download the updated ROM from the motherboard manufacturer's Web site and then run a special program it provides to update the ROM. This procedure is described in more detail later in this chapter.

I recommend that you periodically check with your motherboard manufacturer to see whether an updated BIOS is available for your system. An updated BIOS might contain bug fixes or enable new features not originally found in your system. You might find fixes for IDE hard drive support over 8.4GB or new drivers to support booting from LS-120 (120MB floppy) drives.

Note

For the auto enthusiasts out there, you might want to do the same for your car; that is, check to see whether ROM upgrades are available for your vehicle's computer. Now that updates are so easy and inexpensive, vehicle manufacturers are releasing bug-fix ROM upgrades that correct operational problems or improve vehicle performance. In most cases, you must check with your dealer to see whether any new vehicle ROMs are available. If you have a GM car, GM has a Web site where you can get information about the BIOS revisions available for your car, which it calls Vehicle Calibrations. The GM Vehicle Calibration Information site address is `http://calid.gm.com/vci/`.

When you enter your VIN (vehicle identification number), this page displays the calibration history for the vehicle, which is a list of all the different flash ROM upgrades (calibrations) developed since the vehicle was new. For example, when I entered the VIN on my 1994 Impala, I found that five flash ROM calibrations had been released over the years, and my car had only the second revision installed originally, meaning there had been three newer ROMs than the one I had! The fixes in the various calibration updates are also listed. A trip to the dealer with this information enabled them to use their diagnostic computer to connect to my car and reflash the PCM with the latest software, which, in my case, fixed several problems, including engine surging under specific conditions, shift clunks, erroneous "check engine" light warnings, and several other minor problems.

With the flash ROM capability, I began experimenting with running calibrations originally intended for other vehicles, and I now run a modified Camaro calibration loaded into the flash ROM in my Impala. The spark-advance curve and fuel delivery parameters are much more aggressive in the Camaro calibration, as are the transmission shift points and other features. If you are interested in having a custom program installed in your flash ROM equipped vehicle, I recommend you contact Fastchip at `http://www.fastchip.com` or Superchips at `http://www.superchips.com` (see the Vendor List on the CD for more information). If you want to write and program your own vehicle calibrations, see `http://www.diy-efi.org` for more information.

These days, many objects with embedded computers controlling them are using flash ROMs. Pretty soon you'll be taking your toaster in for flash ROM upgrades as well!

Note

The method for locating and updating your PC motherboard flash ROMs is shown in Chapter 4.

Other devices might have flash ROMs as well; for example, I have updated the flash ROMs in my 3Com ISDN terminal adapter as well as in my Kodak digital camera. Both these items had minor quirks that were fixed by updating their internal ROM code, which was as easy as downloading a file from their respective Web sites and running the update program included in the file.

Flash ROMs are also frequently used to add new capabilities to peripherals or to update peripherals, such as modems, to the latest standards; for example, updating a modem from X2 or K56Flex to V.90 or V.92.

ROM BIOS Manufacturers

A number of popular BIOS manufacturers in the market today supply the majority of motherboard and system manufacturers with the code for their ROMs. This section discusses the various versions available.

Several companies have specialized in the development of a compatible ROM BIOS product. The three major companies that come to mind in discussing ROM BIOS software are American Megatrends, Inc. (AMI), Phoenix Technologies, and Award Software (now owned by Phoenix Technologies). Each company licenses its ROM BIOS to motherboard manufacturers so those manufacturers can worry about the hardware rather than the software. To obtain one of these ROMs for a motherboard, the original equipment manufacturer (OEM) must answer many questions about the design of the system so that the proper BIOS can be either developed or selected from those already designed. Combining a ROM BIOS and a motherboard is not a haphazard task. No single, generic, compatible ROM exists, either. AMI, Award, Microid Research (MR BIOS), and Phoenix ship many variations of their BIOS code to different board manufacturers, each one custom tailored to that specific motherboard.

Recently, some major changes have occurred in the BIOS industry. Intel, the largest BIOS customer, has gone from using mostly Phoenix, to AMI, back to Phoenix, and now back to AMI for most of its motherboards. Intel originally used the Phoenix BIOS core in its motherboards up through 1995, when it changed to an AMI core. It then used AMI until 1997, when it switched back to Phoenix. More recently in 1999 Intel switched again, this time back to AMI. In all these cases Intel, takes the core BIOS from Phoenix or AMI and highly customizes it for its particular motherboards. It is always a big deal which BIOS Intel uses because Intel sells about 80% or more of all PC motherboards. What that basically means is that if you purchase a PC today, you will probably get an Intel-made motherboard with the new AMI BIOS.

Another development is that in late 1998, Phoenix bought Award. While Phoenix continues to sell the Award BIOS as a separate product line, the big-three BIOS developers are now reduced to the big two—Phoenix and AMI. Many of the offshore motherboard manufacturers use the AMI or Award BIOS. Phoenix not only develops the BIOS for many systems, but is also the primary BIOS developer responsible for new BIOS development and new BIOS standards.

OEMs

Many OEMs have developed their own compatible ROMs independently. Companies such as Compaq, AT&T, and Acer have developed their own BIOS products that are comparable to those offered by AMI, Phoenix, Award, and others. These companies also offer upgrades to newer versions that often can provide more features and improvements or fix problems with the older versions. If you use a system with a proprietary ROM, ensure that it is from a larger company with a track record and one that will provide updates and fixes as necessary. Ideally, upgrades should be available for download from the Internet.

Most OEMs have their BIOS written for them by a third-party company. For example, Hewlett-Packard contracts with Phoenix to develop the motherboard BIOSes used in all the HP Vectra PCs. Note that even though Phoenix might have done the development, you still must get upgrades or fixes from Hewlett-Packard. This is really true for all systems because all motherboard manufacturers customize the BIOS for their boards.

AMI

Although AMI customizes the ROM code for a particular system, it does not sell the ROM source code to the OEM. An OEM must obtain each new release as it becomes available. Because many OEMs don't need or want every new version developed, they might skip several version changes before licensing a new one. The AMI BIOS is currently the most popular BIOS in PC systems. Newer versions of the AMI BIOS are called Hi-Flex because of the high flexibility found in the BIOS configuration program. The AMI Hi-Flex BIOS is used in Intel, AMI, and many other manufacturers' motherboards. One special AMI feature is that it is the only third-party BIOS manufacturer to make its own motherboard.

During powerup, the BIOS ID string is displayed on the lower-left part of the screen. This string tells you valuable information about which BIOS version you have and about certain settings that are determined by the built-in setup program.

Tip

A good trick to help you view the BIOS ID string is to shut down and either unplug your keyboard or hold down a key as you power back on. This causes a keyboard error, and the string remains displayed.

You also can download the AMI Motherboard ID Utility program (AMIMBID) from AMI's Web site and run it to determine the contents of ID String 1.

The primary BIOS Identification string (ID String 1) is displayed by any AMI BIOS during the POST at the bottom-left corner of the screen, below the copyright message. Two additional BIOS ID strings (ID Strings 2 and 3) can be displayed by the AMI Hi-Flex BIOS by pressing the Insert key during POST. These additional ID strings display the options installed in the BIOS.

The general BIOS ID String 1 format for older AMI BIOS versions is shown in Table 5.2.

Table 5.2 ABBB-NNNN-mmddyy-KK

Position	Description
A	BIOS Options: D = Diagnostics built in S = Setup built in E = Extended Setup built in

Table 5.2 Continued

Position	Description
BBB	Chipset or Motherboard Identifier: C&T = Chips & Technologies chipset NET = C&T NEAT 286 chipset 286 = Standard 286 motherboard SUN = Suntac chipset PAQ = Compaq motherboard INT = Intel motherboard AMI = AMI motherboard G23 = G2 chipset 386 motherboard
NNNN	The manufacturer license code reference number
mmddyy	The BIOS release date, mm/dd/yy
KK	The AMI keyboard BIOS version number

The BIOS ID String 1 format for AMI Hi-Flex BIOS versions is shown in Table 5.3.

Table 5.3 AB-CCcc-DDDDDD-EFGHIJKL-mmddyy-MMMMMMMM-N

Position	Description
A	Processor Type: 0 = 8086 or 8088 2 = 286 3 = 386 4 = 486 5 = Pentium 6 = Pentium Pro/II/III/Celeron/Athlon/Duron
B	Size of BIOS: 0 = 64KB BIOS 1 = 128KB BIOS 2 = 256KB BIOS
CCcc	Major and minor BIOS version number
DDDDDD	Manufacturer license code reference number 0036xx = AMI 386 motherboard, xx = Series # 0046xx = AMI 486 motherboard, xx = Series # 0056xx = AMI Pentium motherboard, xx = Series # 0066xx = AMI Pentium Pro motherboard, xx = Series #
E	1 = Halt on POST Error
F	1 = Initialize CMOS every boot
G	1 = Block pins 22 and 23 of the keyboard controller
H	1 = Mouse support in BIOS/keyboard controller
I	1 = Wait for <F1> key on POST errors
J	1 = Display floppy error during POST
K	1 = Display video error during POST
L	1 = Display keyboard error during POST
mmddyy	BIOS Date, mm/dd/yy
MMMMMMMM	Chipset identifier or BIOS name
N	Keyboard controller version number

AMI Hi-Flex BIOS ID String 2 is shown in Table 5.4.

Table 5.4 AAB-C-DDDD-EE-FF-GGGG-HH-II-JJJ

Position	Description
AA	Keyboard controller pin number for clock switching.
B	Keyboard controller clock switching pin function: H = High signal switches clock to high speed. L = High signal switches clock to low speed.
C	Clock switching through chipset registers: 0 = Disable. 1 = Enable.
DDDD	Port address to switch clock high.
EE	Data value to switch clock high.
FF	Mask value to switch clock high.
GGGG	Port address to switch clock low.
HH	Data value to switch clock low.
II	Mask value to switch clock low.
JJJ	Pin number for Turbo Switch Input.

AMI Hi-Flex BIOS ID String 3 is shown in Table 5.5.

Table 5.5 AAB-C-DDD-EE-FF-GGGG-HH-II-JJ-K-L

Position	Description
AA	Keyboard controller pin number for cache control.
B	Keyboard controller cache control pin function: H = High signal enables the cache. L = High signal disables the cache.
C	1 = High signal is used on the keyboard controller pin.
DDD	Cache control through chipset registers: 0 = Cache control off. 1 = Cache control on.
EE	Port address to enable cache.
FF	Data value to enable cache.
GGGG	Mask value to enable cache.
HH	Port address to disable cache.
II	Data value to disable cache.
JJ	Mask value to disable cache.
K	Pin number for resetting the 82335 memory controller.
L	BIOS Modification Flag: 0 = The BIOS has not been modified. 1–9, A–Z = Number of times the BIOS has been modified.

The AMI BIOS has many features, including a built-in setup program activated by pressing the Delete or Esc key in the first few seconds of booting up your computer. The BIOS prompts you briefly as to which key to press and when to press it. The AMI BIOS offers user-definable hard disk types, essential for optimal use of many IDE or ESDI drives. The 1995 and newer BIOS versions also support enhanced IDE drives and autoconfigure the drive parameters.

A unique feature of some of the AMI BIOS versions was that in addition to the setup, they had a built-in, menu-driven diagnostics package, essentially a very limited version of the standalone AMIDIAG product. The internal diagnostics are not a replacement for more comprehensive disk-based programs, but they can help in a pinch. The menu-driven diagnostics do not do extensive memory testing, for example, and the hard disk low-level formatter works only at the BIOS level rather than at the controller register level. These limitations often have prevented it from being capable of formatting severely damaged disks. Most newer AMI BIOS versions no longer include the full diagnostics.

AMI doesn't produce BIOS documentation; it leaves that up to the motherboard manufacturers who include their BIOS on the motherboard. However, AMI has published a detailed version of its documentation called the *Programmer's Guide to the AMIBIOS: Includes Descriptions of PCI, APM, and Socket Services BIOS Functions*, published by Windcrest/McGraw-Hill, ISBN 0-07-001561-9. This book, written by AMI engineers, describes all the BIOS functions, features, error codes, and more. Unfortunately, this book is out of print. If you can locate it, I recommend this book for users with an AMI BIOS in their systems because this provides a complete version of the documentation for which they might have been looking.

The AMI BIOS is sold through distributors, a list of which is available at its Web site. However, keep in mind that you can't buy upgrades and replacements directly from AMI, and AMI produces upgrades only for its own motherboards. If you have a non-AMI motherboard with a customized AMI BIOS, you must contact the motherboard manufacturer for an upgrade.

Award

Just as Award Software did before its merger with Phoenix, Phoenix continues to sell the Award BIOS code to the OEM and allows the OEM to customize the BIOS. Of course, the BIOS no longer is Award BIOS then, but rather a highly customized version. This permits the OEM to have total control over the BIOS code without having to write it from scratch.

By contrast, neither the Phoenix BIOS nor the AMI BIOS source code is sold to OEM customers. Phoenix and AMI customize their BIOS code for each customer's needs, but they retain control of it. Some OEMs that seem to have developed their own ROM code started with a base of source code licensed to them by Award or some other company.

The Award BIOS has all the features you expect, including a built-in setup program activated by pressing Ctrl+Alt+Esc or a particular key on startup (usually prompted on the screen). This setup offers user-definable drive types, required to fully use IDE or ESDI hard disks. The POST is good, although the few beep codes supported means that a POST card is necessary if you want to diagnose most power-on problems. Phoenix provides technical support on its Web site at `http://www.phoenix.com`. Phoenix purchased Award in late 1998 but continues to release Award BIOS products for the OEM market. eSupport.com (formerly Unicore Software) provides Award BIOS upgrades for end users.

Phoenix

The Phoenix BIOS for many years has been a standard of compatibility by which others are judged. It was one of the first third-party companies to legally reverse-engineer the IBM BIOS using a *clean-room* approach. In this approach, a group of engineers studied the IBM BIOS and wrote a specification for how that BIOS should work and what features should be incorporated. This information then was passed to a second group of engineers who had never seen the IBM BIOS. They could then legally write a new BIOS to the specifications set forth by the first group. This work was then unique and not a copy of IBM's BIOS; however, it functioned the same way.

The Phoenix BIOS excels in two areas that put it high on my list of recommendations. One is that the POST is excellent. The BIOS outputs an extensive set of beep codes that can be used to diagnose severe motherboard problems that would prevent normal operation of the system. In fact, with beep codes alone, this POST can isolate memory failures in Bank 0 right down to the individual SIMM or DIMM module. The Phoenix BIOS also has an excellent setup program free from unnecessary frills, but one that offers all the features the user would expect, such as user-definable drive types and so on. The built-in setup is activated by pressing Ctrl+Alt+S, Ctrl+Alt+Esc, or a particular key on startup, such as F1 or F2 on most newer systems, depending on the version of BIOS you have.

The second area in which Phoenix excels is the documentation. Not only are the manuals you get with the system detailed, but Phoenix has also written a set of BIOS technical-reference manuals that are a standard in the industry. The original set consists of three books, titled *System BIOS for IBM PC/XT/AT Computers and Compatibles*, *CBIOS for IBM PS/2 Computers and Compatibles*, and *ABIOS for IBM PS/2 Computers and Compatibles;* an updated version is called *System BIOS for IBM PCs, Compatibles, and EISA Computers: The Complete Guide to ROM-Based System Software*. In addition to being an excellent reference for the Phoenix BIOS, these books serve as an outstanding overall reference to the BIOS in general. These are out of print but might be available through bookfinder services.

Phoenix has extensive technical support and documentation on its Web site at `http://www.phoenix.com`, as does its largest nationwide distributor, Micro Firmware, Inc., at `http://www.firmware.com`, or check the phone numbers listed in the Vendor List on the CD. Micro Firmware offers upgrades to some older systems with a Phoenix BIOS, including many Packard Bell, Gateway (with Micronics motherboards), Micron Technologies, and other systems. For most systems, especially newer ones, you need to get any BIOS updates from the system or motherboard manufacturer.

These companies' products are established as ROM BIOS standards in the industry, and frequent updates and improvements ensure that a system containing these ROMs will have a long life of upgrades and service.

Microid Research (MR) BIOS

Microid Research is an interesting BIOS supplier. It primarily markets upgrade BIOSes for older Pentium and 486 motherboards that were abandoned by their original manufacturers. As such, it is an excellent upgrade for adding new features and performance to an older system. Microid Research BIOS upgrades are sold through eSupport.com (Unicore Software).

Tip

If you support several BIOS types, consider adding Phil Croucher's *The BIOS Companion* to your bookshelf or PDF file collection. This book provides detailed BIOS options and configuration information for today's leading BIOSes. You can purchase various editions from Amazon.com and other bookstores, but for the most up-to-date (and least expensive) edition, I suggest ordering the PDF (Adobe Acrobat) version of *The BIOS Companion - Engineer's Edition* from Electrocution.com.

Upgrading the BIOS

In this section, you learn how ROM BIOS upgrades can improve a system in many ways. You also learn why upgrades can be difficult and can require much more than plugging in a generic set of ROM chips.

The ROM BIOS provides the crude brains that get your computer's components working together. A simple BIOS upgrade can often give your computer better performance and more features.

The BIOS is the reason various operating systems can operate on virtually any PC-compatible system despite hardware differences. Because the BIOS communicates with the hardware, the BIOS must be specific to the hardware and match it completely. As discussed earlier, instead of creating their own BIOSes, many computer makers buy a BIOS from specialists such as American Megatrends, Inc. (AMI), Microid Research, or Phoenix Technologies Ltd. (for Phoenix and AwardBIOS). A motherboard manufacturer that wants to license a BIOS must undergo a lengthy process of working with the BIOS company to tailor the BIOS code to the hardware. This process is what makes upgrading a BIOS somewhat problematic; the BIOS usually resides on ROM chips on the motherboard and is specific to that motherboard model or revision. In other words, you must get your BIOS upgrades from your motherboard manufacturer or from a BIOS upgrade company that supports the motherboard you have, rather than directly from the BIOS developer.

Often, in older systems, you must upgrade the BIOS to take advantage of some other upgrade. To install some of the larger and faster IDE (Integrated Drive Electronics) hard drives and LS-120 (120MB) floppy drives in older machines, for example, you might need a BIOS upgrade. Some of the machines you have might be equipped with older BIOSes that do not support hard drives larger than 8GB, for example.

The following list shows the primary functions of a ROM BIOS upgrade:

- Adding LS-120 (120MB) floppy drive support (also known as a SuperDisk)
- Adding support for hard drives greater than 8GB
- Adding support for Ultra-DMA/33, UDMA/66, or UDMA/100 IDE hard drives
- Adding support for bootable ATAPI CD-ROM drives (called the El Torito specification)
- Adding or improving Plug and Play (PnP) support and compatibility
- Correcting calendar-related and leap-year bugs
- Correcting known bugs or compatibility problems with certain hardware and application or operating system software
- Adding support for newer-type and -speed processors
- Adding support for ACPI power management

If you install newer hardware or software and follow all the instructions properly, but you can't get it to work, specific problems might exist with the BIOS that an upgrade can fix. This is especially true for newer operating systems. Many systems need to have a BIOS update to properly work with the Plug and Play features of Windows 9x, Me, XP, and 2000. Because these problems are random and vary from board to board, it pays to periodically check the board manufacturer's Web site to see whether any updates are posted and what problems they fix.

You can use the BIOS Wizard utility available from eSupport.com (formerly Unicore) to test your BIOS for compatibility with popular BIOS features, such as Zip/LS-120 booting, ACPI power management, PCI IRQ routing, and more. Download it from `http://www.esupport.com/techsupport/award/awardutils.htm`.

Where to Get Your BIOS Update

For most BIOS upgrades, you must contact the motherboard manufacturer by phone or download the upgrade from its Web site. The BIOS manufacturers do not offer BIOS upgrades because the BIOS in your motherboard did not actually come from them. In other words, although you think you have a

Phoenix, AMI, or Award BIOS, you really don't! Instead, you have a custom version of one of these BIOSes, which was licensed by your motherboard manufacturer and uniquely customized for its board. As such, you must get any BIOS upgrades from the motherboard manufacturer because they must be customized for your board as well.

In the case of Phoenix or Award, another option might exist. A company called Unicore specializes in providing Award BIOS upgrades. Unicore might be able to help you out if you can't find your motherboard manufacturer or if it is out of business. Phoenix has a similar deal with Micro Firmware, a company it has licensed to provide various BIOS upgrades. If you have a Phoenix or an Award BIOS and your motherboard manufacturer can't help you, contact one of these companies for a possible solution. Microid Research (sold through Unicore) is another source of BIOS upgrades for a variety of older and otherwise obsolete boards. These upgrades are available for boards that originally came with AMI, Award, or Phoenix BIOSes, and they add new features to older boards that have been abandoned by their original manufacturers. Contact Microid or Unicore for more information.

Determining Your BIOS Version

When seeking a BIOS upgrade for a particular motherboard (or system), you need to know the following information:

- The make and model of the motherboard (or system)
- The version of the existing BIOS
- The type of CPU (for example, Pentium MMX, AMD K6, Cyrix/IBM 6x86MX, MII, Pentium II, Pentium III and later, AMD Athlon, and so on)

You usually can identify the BIOS you have by watching the screen when the system is first powered up. It helps to turn on the monitor first because some take a few seconds to warm up, and often the BIOS information is displayed for only a few seconds.

Note

Many newer PCs now do not display the typical POST screen. Instead, many show a logo for the motherboard or PC manufacturer, which is usually referred to as a *splash screen*. To enter BIOS Setup, you must press a key or keys (specific to the BIOS manufacturer). See the section "Running or Accessing the CMOS Setup Program," later in this chapter, for more information. You might hear some in the industry refer to displaying a manufacturer's logo instead of the default POST screen as a *quiet boot*. Often you can change these BIOS splash screens to your own liking, even including your own company logo or graphic of choice. Intel has free software at `http://developer.intel.com/design/motherbd/gen_indx.htm` that enables you to change or restore the splash screen on Intel motherboards.

Tip

Look for any copyright notices or part number information. Sometimes you can press the Pause key on the keyboard to freeze the POST, allowing you to take your time to write down the information. Pressing any other key then causes the POST to resume.

In addition, you often can find the BIOS ID information in the BIOS Setup screens. eSupport.com/Unicore Software also offers a downloadable BIOS Agent that can be used to determine this information, as well as the motherboard chipset and Super I/O chip used by your motherboard. After you have this information, you should be able to contact the motherboard manufacturer to see whether a new BIOS is available for your system. If you go to the Web site, check to see whether a version exists that is newer than the one you have. If so, you can download it and install it in your system.

Most BIOSes display version information onscreen when the system is first powered up. In some cases, the monitor takes too long to warm up, and you might miss this information because it is displayed for only a few seconds. Try turning on your monitor first, and then your system, which makes this information easier to see. You usually can press the Pause key on the keyboard when the BIOS ID information is being displayed; this freezes it so you can record the information. Pressing any other key allows the system startup to resume.

Part of the PC 2001 standard published by Intel and Microsoft requires something called Fast POST to be supported. Fast POST means that the time it takes from turning on the power until the system starts booting from disk must be 12 seconds or less (for systems not using SCSI as the primary storage connection). This time limit includes the initialization of the keyboard, video card, and ATA bus. For systems containing adapters with onboard ROMs, an additional 4 seconds are allowed per ROM. Intel calls this feature Rapid Bios Boot (RBB), and it is supported in all their motherboards from 2001 and beyond—some of which can begin booting from power-on in as little as 6 seconds.

Backing Up Your BIOS's CMOS Settings

A motherboard BIOS upgrade usually wipes out the BIOS Setup settings in the CMOS RAM. Therefore, you should record these settings, especially the important ones such as hard disk parameters. Some software programs, such as the Norton Utilities, can save and restore CMOS settings, but unfortunately, these types of programs are often useless in a BIOS upgrade situation. This is because sometimes the new BIOS offers new settings or changes the positions of the stored data in the CMOS RAM, which means you don't want to do an exact restore. Also, with the variety of BIOSes available, I have yet to find a CMOS RAM backup and restore program that works on more than just a few specific systems.

You are better off manually recording your BIOS Setup parameters, or possibly connecting a printer to your system and using the Shift+Prtsc (Print Screen) function to print out each of the setup screens. Some shareware programs could print or even save and restore the BIOS Setup settings stored in the CMOS RAM, but these were BIOS version specific and would not work on any other system. Most of these programs were useful during the 286/386 era, but most systems released since—especially those with Plug and Play capabilities—have rendered most of these older programs useless.

Keyboard-Controller Chips

In addition to the main system ROM, older AT-class (286 and later) computers also have a keyboard controller or keyboard ROM, which is a keyboard-controller microprocessor with its own built-in ROM. This often is found in the Super I/O or South Bridge chips on most newer boards. The keyboard controller was originally an Intel 8042 microcontroller, which incorporates a microprocessor, RAM, ROM, and I/O ports. This was a 40-pin chip that often had a copyright notice identifying the BIOS code programmed into the chip. Modern motherboards have this function integrated into the chipset, specifically the Super I/O or South Bridge chips, so you won't see the old 8042 chip anymore.

The keyboard controller controls the reset and A20 lines and also deciphers the keyboard scan codes. The A20 line is used in extended memory and other protected-mode operations. In many systems, one of the unused ports is used to select the CPU clock speed. Because of the tie-in with the keyboard controller and protected-mode operation, many problems with keyboard controllers became evident on these older systems when upgrading from DOS to Windows 95/98, NT, or Windows 2000.

Problems with the keyboard controller were solved in most systems in the early 1990s, so you shouldn't have to deal with this issue in systems newer than that. With older systems, when you upgraded the BIOS in the system, the BIOS vendor often included a new keyboard controller.

Using a Flash BIOS

Virtually all PCs built since 1996 include a flash ROM to store the BIOS. A flash ROM is a type of EEPROM chip you can erase and reprogram directly in the system without special equipment. Older

EPROMs required a special ultraviolet light source and an EPROM programmer device to erase and reprogram them, whereas flash ROMs can be erased and rewritten without even removing them from the system.

Using flash ROM enables you to download ROM upgrades from a Web site or to receive them on disk; you then can load the upgrade into the flash ROM chip on the motherboard without removing and replacing the chip. Normally, these upgrades are downloaded from the manufacturer's Web site, and then an included utility is used to create a bootable floppy with the new BIOS image and the update program. It is important to run this procedure from a boot floppy so that no other software or drivers are in the way that might interfere with the update. This method saves time and money for both the system manufacturer and end user.

Sometimes the flash ROM in a system is write-protected, and you must disable the protection before performing an update—usually by means of a jumper or switch that controls the lock on the ROM update. Without the lock, any program that knows the correct instructions can rewrite the ROM in your system—not a comforting thought. Without the write-protection, virus programs could be written that copy themselves directly into the ROM BIOS code in your system. Even without a physical write-protect lock, modern flash ROM BIOSes have a security algorithm that helps prevent unauthorized updates. This is the technique Intel uses on its motherboards.

Note that motherboard manufacturers will not notify you when they upgrade the BIOS for a particular board. You must periodically log in to their Web sites to check for updates. Usually, any flash updates are free.

Before proceeding with a BIOS upgrade, you first must locate and download the updated BIOS from your motherboard manufacturer. Consult the Vendor List on the CD to find the Web site address or other contact information for your motherboard manufacturer. Log in to its Web site, and follow the menus to the BIOS updates page; then select and download the new BIOS for your motherboard.

The BIOS upgrade utility is contained in a self-extracting archive file that can initially be downloaded to your hard drive, but it must be extracted and copied to a floppy before the upgrade can proceed. Different motherboard manufacturers have slightly different procedures and programs to accomplish a flash ROM upgrade, so you should read the directions included with the update. I include instructions here for Intel motherboards because they are by far the most common.

Intel and other typical flash BIOS upgrades fit on a bootable floppy disk. Older Intel and some other flash BIOS upgrades also provide the capability to save and verify the current BIOS version before replacing it with the new version and also provide the capability to install alternative languages for BIOS messages and the BIOS setup utility.

The first step in the upgrade after downloading the new BIOS file is to enter the CMOS Setup and write down your existing CMOS settings because they will be erased during the upgrade. Then, you create a DOS boot floppy and uncompress or extract the BIOS upgrade files to the floppy from the file you downloaded. Next, you reboot on the newly created upgrade disk and follow the menus for the actual reflash procedure.

The iFlash procedure covered in this section is similar to the BIOS update process used by most non-Intel motherboards and must be used for systems running Windows 95, MS-DOS, or non-Windows operating systems such as Linux. Intel's Express BIOS update (for Windows 98, Windows NT 4, and current Windows versions) uses the InstallShield loader program familiar to Windows users to install BIOS upgrades within the Windows GUI. Here is a step-by-step procedure for the process using Intel's iFlash (DOS-based) BIOS update:

1. Save your CMOS RAM setup configuration. You can do so by pressing the appropriate key during boot to start the BIOS setup program (usually F1 with an AMI BIOS and F2 with a Phoenix BIOS) and writing down all your current CMOS settings. You also might be able to print the

screens if you have a printer connected, using the PrtScr key on the keyboard. You must reset these settings after you have upgraded to the latest BIOS. Write down all settings that are unique to the system. These settings will be needed later to reconfigure the system. Pay special attention to any hard drive settings for geometry (Cylinder/Head/Sectors per track) and translation (LBA, Large, CHS); these are very important. If you fail to restore these properly, you might not be able to boot from the drive or access the data on it.

2. Exit the BIOS Setup and restart the system. Allow the system to fully start Windows and bring up a DOS prompt window or boot directly to a DOS prompt via the Windows Start menu (for example, press F8 when you see Starting Windows, and select Command Prompt).
3. Place a formatted blank floppy disk in the A: floppy drive. If the disk contains data, format the floppy using the normal format command:

   ```
   C:\>FORMAT A:
   ```

   You also can use Windows Explorer to format the floppy disk.
4. The file you originally downloaded from the Intel Web site is a self-extracting compressed archive that includes other files that need to be extracted. Put the file in a temporary directory, and then from within this directory, double-click the BIOS file you downloaded or type the filename of the file and press Enter. This causes the file to self-extract. For example, if the file you downloaded is called `CB-P06.EXE` (for the Intel D810E2CB motherboard), you would enter the following command:

   ```
   C:\TEMP>CB-P06 <enter>
   ```

5. The extracted files are stored in the same temporary folder as the downloaded BIOS. Recent Intel flash BIOS upgrades contain the following files: `Desc.txt`, `License.txt`, `Readme.txt`, `Run.bat` (which is run to create the bootable floppy), and `SW.EXE` (which contains the BIOS code).
6. To create the bootable floppy disk, open `Run.bat`, which extracts files from `SW.EXE`s and transfer the necessary files to the blank disk in Drive A:.
7. Now you can restart the system with the bootable floppy in drive A: containing the new BIOS files you just extracted. Upon booting from this disk, the iFLASH program automatically starts and updates the BIOS boot block and the main BIOS area.
8. When you're told that the BIOS has been successfully loaded, remove the bootable floppy from the drive and press Enter to reboot the system.
9. Press F1 or F2 to enter Setup. On the first screen within Setup, check the BIOS version to ensure that it is the new version.
10. In Setup, load the default values. If you have an AMI BIOS, press the F5 key. With a Phoenix BIOS, go to the Exit submenu and highlight Load Setup Defaults, and then press Enter.

Caution

If you do not set the values back to default, the system might function erratically.

11. If the system had unique settings, reenter those settings now. Press F10 to save the values, exit Setup, and restart the system. Your system should now be fully functional with the new BIOS.

Note

If you encounter a CMOS checksum error or other problems after rebooting, try rebooting the system again. CMOS checksum errors require that you enter Setup, check and save your settings, and exit Setup a second time.

Note

The procedure for older Intel BIOS upgrades differs from that described previously. If your BIOS upgrade contains the `BIOS.EXE` program, see the BIOS upgrade description contained in *Upgrading and Repairing PCs, 12th Edition*, included in electronic form on the CD-ROM packaged with this book.

Flash BIOS Recovery

When you performed the flash reprogramming, you should have seen a warning message onscreen similar to the following:

```
The BIOS is currently being updated. DO NOT REBOOT OR POWER DOWN until the update
➥is completed (typically within three minutes)...
```

If you fail to heed this warning or something interrupts the update procedure, you will be left with a system that has a corrupted BIOS. This means you will not be able to restart the system and redo the procedure, at least not easily. Depending on the motherboard, you might have to replace the flash ROM chip with one that was preprogrammed by the motherboard manufacturer. This is an unfortunate necessity because your board will be nonfunctional until a noncorrupted ROM is present. This is why I still keep my trusty ROM burner around; it is very useful for those motherboards with socketed flash ROM chips. In minutes, I can use the ROM burner to reprogram the chip and reinstall it in the board. If you need a ROM programmer, I recommend Andromeda Research (see the Vendor List on the CD).

In many of the latest systems, the flash ROM is soldered into the motherboard so it can't be replaced, rendering the reprogramming idea moot. However, this doesn't mean the only way out is a complete motherboard replacement. Most motherboards with soldered-in flash ROMs have a special BIOS Recovery procedure that can be performed. This hinges on a special nonerasable part of the flash ROM that is reserved for this purpose.

In the unlikely event that a flash upgrade is interrupted catastrophically, the BIOS might be left in an unusable state. Recovering from this condition requires the following steps. A minimum of a power supply, a speaker, and a floppy drive configured as drive A: should be attached to the motherboard for this procedure to work:

1. Change the Flash Recovery jumper to the recovery mode position. Virtually all Intel motherboards and many third-party motherboards have a jumper or switch for BIOS recovery, which in most cases is labeled "Recover/Normal." Figure 5.6 shows this jumper on the Intel SE440BX, a typical motherboard.
2. Install the bootable BIOS upgrade disk you previously created to do the flash upgrade into drive A: and reboot the system.

   Because of the small amount of code available in the nonerasable flash boot block area, no video prompts are available to direct the procedure. So, you will see nothing onscreen. In fact, it is not even necessary for a video card to be connected for this procedure to work. The procedure can be monitored by listening to the speaker and looking at the floppy drive LED. When the system beeps and the floppy drive LED is lit, the system is copying the BIOS recovery code into the flash device.
3. As soon as the drive LED goes off and the system beeps (normally twice), the recovery should be complete. Sometimes there might be pauses where the drive stops reading during the recovery process; however, the process might not be complete. Be sure to wait for a minute or so to ensure a complete recovery before turning off the system. When you are sure the recovery is complete and there is no further activity, power off the system.
4. Change the flash recovery jumper back to the default position for normal operation.

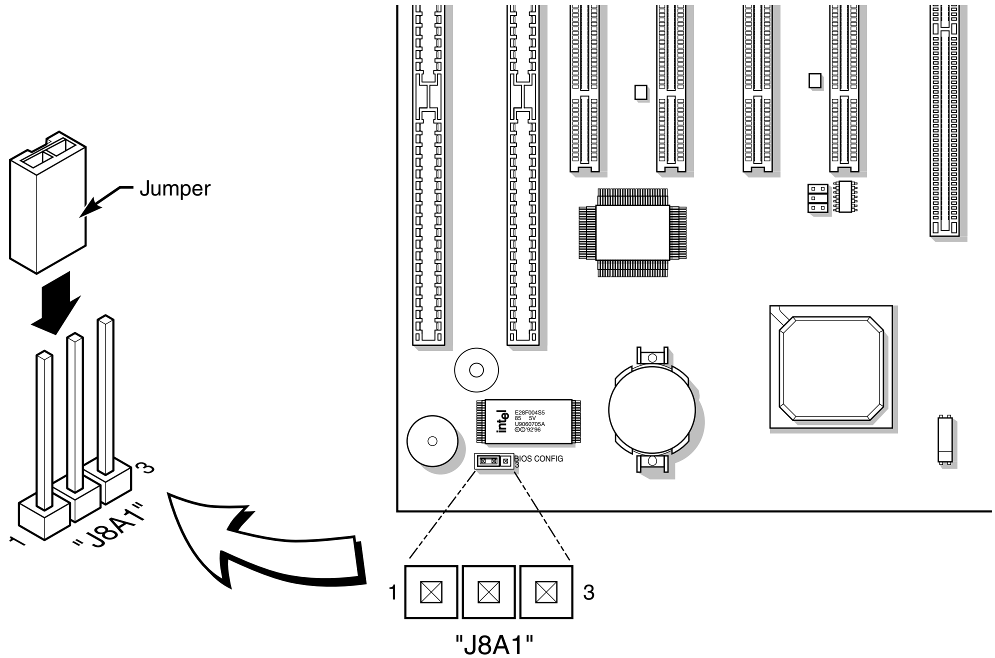

Figure 5.6 Typical Intel motherboard BIOS recovery jumper.

When you power the system back on, the new BIOS should be installed and functional. However, you might want to leave the BIOS upgrade floppy in drive A: and check to see that the proper BIOS version was installed.

Note

Note that this BIOS recovery procedure is often the fastest way to update a large number of machines, especially if you are performing other upgrades at the same time. This is how it is normally done in a system assembly or production environment.

Using IML System Partition BIOS

IBM and Compaq used a scheme similar to a flash ROM, called Initial Microcode Load (IML), in some of their older Pentium and 486 systems. IML is a technique in which the BIOS code is installed on the hard disk in a special hidden-system partition and is loaded every time the system is powered up. Of course, the system still has a core BIOS on the motherboard, but all that BIOS does is locate and load updated BIOS code from the system partition. This technique enabled Compaq and IBM to distribute ROM updates on disk for installation in the system partition. The IML BIOS is loaded every time the system is reset or powered on.

Along with the system BIOS code, the system partition contains a complete copy of the Setup and Diagnostics or Reference Disk, which provides the option of running the setup and system-configuration software at any time during a reboot operation. This option eliminates the need to boot from this disk to reconfigure the system and gives the impression that the entire Setup and Diagnostics or Reference Disk is contained in ROM.

One drawback to this technique is that the BIOS code is installed on the hard disk; the system can't function properly without the correctly set-up hard disk connected. You always can boot from the

Reference Disk floppy should the hard disk fail or become disconnected, but you can't boot from a standard floppy disk.

Caution

This scheme makes hard drive updates problematic and causes all kinds of support nightmares. I recommend avoiding any system with an IML BIOS, especially if you are buying it used, because support for these types of configurations is hard to come by and not many people know how to deal with them.

Motherboard CMOS RAM Addresses

In the original IBM AT system, a Motorola 146818 chip was used as the RTC (real-time clock) and CMOS (complementary metal-oxide semiconductor) RAM chip. This special chip had a simple digital clock that used 10 bytes of RAM and an additional 54 more bytes of leftover RAM in which you could store anything you wanted. The designers of the IBM AT used these extra 54 bytes to store the system configuration.

Modern PC systems don't use the Motorola chip; instead, they incorporate the functions of this chip into the motherboard chipset (South Bridge) or Super I/O chip, or they use a special battery and NVRAM (nonvolatile RAM) module from companies such as Dallas or Benchmarq.

Table 5.6 shows the standard format of the information stored in the 64-byte standard CMOS RAM module. This information controls the configuration of the system and is read and written by the system setup program.

Table 5.6 CMOS RAM Addresses

Offset (hex)	Offset (dec)	Field Size	Function
00h	0	1 byte	Current second in BCD (00–59)
01h	1	1 byte	Alarm second in BCD
02h	2	1 byte	Current minute in BCD (00–59)
03h	3	1 byte	Alarm minute in BCD
04h	4	1 byte	Current hour in BCD (00–23)
05h	5	1 byte	Alarm hour in BCD
06h	6	1 byte	Current day of week in BCD (00–06)
07h	7	1 byte	Current day of month in BCD (00–31)
08h	8	1 byte	Current month in BCD (00–12)
09h	9	1 byte	Current year in BCD (00–99)
0Ah	10	1 byte	Status register A
0Bh	11	1 byte	Status register B
0Ch	12	1 byte	Status register C
0Dh	13	1 byte	Status register D
0Eh	14	1 byte	Diagnostic status
0Fh	15	1 byte	Shutdown code
10h	16	1 byte	Floppy drive types
11h	17	1 byte	Advanced BIOS Setup options
12h	18	1 byte	Hard disk 0/1 types (0–15)

Table 5.6 Continued

Offset (hex)	Offset (dec)	Field Size	Function
13h	19	1 byte	Keyboard typematic rate and delay
14h	20	1 byte	Installed equipment
15h	21	1 byte	Base memory in 1K multiples, LSB
16h	22	1 byte	Base memory in 1K multiples, MSB
17h	23	1 byte	Extended memory in 1K multiples, LSB
18h	24	1 byte	Extended memory in 1K multiples, MSB
19h	25	1 byte	Hard Disk 0 Extended Type (0–255)
1Ah	26	1 byte	Hard Disk 1 Extended Type (0–255)
1Bh	27	8 bytes	Hard Disk 0 user-defined type information
24h	36	8 bytes	Hard Disk 1 user-defined type information
2Dh	45	1 byte	Advanced BIOS Setup options
2Eh	46	1 byte	CMOS checksum MSB
2Fh	47	1 byte	CMOS checksum LSB
30h	48	1 byte	POST reported extended memory LSB
31h	49	1 byte	POST reported extended memory MSB
32h	50	1 byte	Date century in BCD (00–99)
33h	51	1 byte	POST information flag
34h	52	2 bytes	Advanced BIOS Setup options
36h	54	1 byte	Chipset-specific BIOS Setup options
37h	55	7 bytes	Power-On Password (usually encrypted)
3Eh	62	1 byte	Extended CMOS checksum MSB
3Fh	63	1 byte	Extended CMOS checksum LSB

BCD = Binary-coded decimal
LSB = Least significant byte
MSB = Most significant byte
POST = Power on self test

Note that many newer systems have extended CMOS RAM with 2KB, 4KB, or more. The extra room is used to store the Plug and Play information detailing the configuration of adapter cards and other options in the system. As such, no 100% compatible standard exists for how CMOS information is stored in all systems. You should consult the BIOS manufacturer for more information if you want the full details of how CMOS is stored because the CMOS configuration and Setup program typically are part of the BIOS. This is another example of how close the relationship is between the BIOS and the motherboard hardware.

Backup programs and utilities are available in the public domain for CMOS RAM information, which can be useful for saving and later restoring a configuration. Unfortunately, these programs are BIOS specific and function only on a BIOS for which they are designed. As such, I don't normally rely on these programs because they are too motherboard and BIOS specific and will not work on all my systems seamlessly.

Table 5.7 shows the values that might be stored by your system BIOS in a special CMOS byte called the diagnostics status byte. By examining this location with a diagnostics program, you can determine whether your system has set trouble codes, which indicate that a problem previously has occurred.

Table 5.7 CMOS RAM Diagnostic Status Byte Codes

Bit Number 7	6	5	4	3	2	1	0	Hex	Function
1	•	•	•	•	•	•	•	80	Real-time clock (RTC) chip lost power.
•	1	•	•	•	•	•	•	40	CMOS RAM checksum is bad.
•	•	1	•	•	•	•	•	20	Invalid configuration information found at POST.
•	•	•	1	•	•	•	•	10	Memory size compare error at POST.
•	•	•	•	1	•	•	•	08	Fixed disk or adapter failed initialization.
•	•	•	•	•	1	•	•	04	Real-time clock (RTC) time found invalid.
•	•	•	•	•	•	1	•	02	Adapters do not match configuration.
•	•	•	•	•	•	•	1	01	Time-out reading an adapter ID.
•	•	•	•	•	•	•	•	00	No errors found (Normal).

If the diagnostic status byte is any value other than `0`, you typically get a CMOS configuration error on bootup. These types of errors can be cleared by rerunning the setup program.

Replacing a BIOS ROM

Systems dating from 1995 or earlier usually don't have a flash ROM and instead use an EPROM. To upgrade the BIOS in one of these systems, you replace the EPROM chip with a new one preloaded with the new BIOS. As with a flash ROM upgrade, you must get this from your motherboard manufacturer. There is usually a fee for this because the manufacturer must custom-burn a chip just for you and mail it out. Most boards older than 1995 are probably not worth upgrading the BIOS on, so weigh this option carefully! It doesn't make sense to spend $50 on a new BIOS for an ancient board when a new Pentium or Pentium II board can be had for $75, and that new board will include a flash BIOS and many other new features.

The procedure for replacing the BIOS chip is also useful if you have made a backup copy of your socketed system BIOS chip and need to replace a damaged original with the backup copy.

To replace the BIOS chip, follow these steps:

1. Back up the CMOS RAM settings.
2. Power down the system and unplug the power cord.
3. Remove the cover and any other components in the way of the BIOS EPROM chip. Remember to use caution with respect to static discharges; you should wear an antistatic wrist strap for this procedure or ground yourself to the chassis before touching any internal components.
4. Using a chip puller or a thin flat-blade screwdriver, gently pry the chip out of its socket.
5. Remove the new EPROM from the antistatic packing material in which it came.
6. Install the new EPROM chip into the socket.
7. Reinstall anything you removed to gain access to the chip.
8. Put the cover back on, plug in the system, and power on.
9. Enter the BIOS setup information you saved earlier.
10. Reboot and enjoy the new BIOS!

As you can see, things are much easier with a modern motherboard with a flash ROM because you usually don't even have to remove the lid.

CMOS Setting Specifications

The CMOS RAM must be configured with information about your system's drives and user-selected options before you can use your computer. The Setup program provided with your system is used to select the options you want to use to start your computer.

Running or Accessing the CMOS Setup Program

If you want to run the BIOS Setup program, you usually have to reboot and press a particular key or key combination during the POST. The major vendors have standardized the following keystrokes to enter the BIOS Setup:

- *AMI BIOS*. Press Delete during POST.
- *Phoenix BIOS*. Press F2 during POST.
- *Award BIOS*. Press Delete or Ctrl+Alt+Esc during POST.
- *Microid Research BIOS*. Press Esc during POST.

If your system will not respond to one of these common keystroke settings, you might have to contact the manufacturer or read the system documentation to find the correct keystrokes.

Some unique ones are as follows:

- *IBM Aptiva/Valuepoint*. Press F1 during POST.
- *Older Phoenix BIOS*. Boot to a safe mode DOS command prompt, and then press Ctrl+Alt+Esc or Ctrl+Alt+S.
- *Compaq*. Press F10 during POST.

After you are at the BIOS Setup main screen, you'll usually find a main menu allowing access to other menus and submenus of different sections or screens. Using the Intel DB815EEA motherboard as an example (one of Intel's newer motherboards), let's go through all the menus and submenus of this typical motherboard. Although other motherboards might feature slightly different settings, most are very similar.

BIOS Setup Menus

Most modern BIOSes offer a menu bar at the top of the screen when you're in the BIOS Setup that controls navigation through the various primary menus. A typical menu bar offers the choices shown in Table 5.8.

Note

Because most common BIOSes use similar settings, I've chosen the Setup used by modern Intel motherboards to use as an example in the following tables. Because the BIOS is customized by the motherboard manufacturer, even the same BIOS might offer different options for different boards. The settings covered here will help you get a general idea of the type of settings to expect and how the BIOS Setup settings affect your computer.

Table 5.8 Typical BIOS Setup Menus*

Setup Menu Screen	Description
Maintenance	Specifies the processor speed and clears the setup passwords. This menu is available only in Configure mode, set by a jumper on the board.
Main	Allocates resources for hardware components.

Table 5.8 Continued

Setup Menu Screen	Description
Advanced	Specifies advanced features available through the chipset.
Security	Specifies passwords and security features.
Power	Specifies power management features.
Boot	Specifies boot options and power supply controls.
Exit	Saves or discards changes to the setup program options.

**Based on the BIOS used by the Intel DB815EEA motherboard. Used by permission of Intel Corporation.*

Choosing each of these selections takes you to another menu with more choices. The following sections examine all the choices available in a typical motherboard, such as the Intel DB815EEA.

Maintenance Menu

The Maintenance menu is a special menu for setting the processor speed and clearing the setup passwords. Older motherboards used jumpers to configure the processor bus speed (motherboard speed) and processor multiplier. Most newer boards from Intel and others now offer this control via the BIOS Setup rather than moving jumpers. In the case of Intel, one jumper still remains on the board called the configuration jumper, which must be set to Configure mode for the Maintenance menu to be available.

Setup displays this menu only if the system is set in Configure mode. To set Configure mode, power off the system and move the configuration jumper on the motherboard from *Normal* to *Configure* (see Figure 5.6, earlier in this chapter). Because this is the only jumper on a modern Intel board, it is pretty easy to find. When the system is powered back on, the BIOS Setup automatically runs, and you will be able to select the Maintenance menu shown in Table 5.9. After making changes and saving, power off the system and reset the jumper to Normal mode for normal operation.

Table 5.9 Typical Maintenance Menu Settings*

Feature	Options	Description
Processor Speed	MHz	Specifies the processor speed in megahertz. This setup screen shows only speeds up to and including the maximum speed of the processor installed on the motherboard.
Clear All Passwords	No options	Clears the user and supervisor passwords.
Clear BiS	No options	Clears the Wired for Management Boot Integrity Service (BiS) credentials.
Extended Configuration	User-defined options	Displays Extended Configuration Submenu.
CPU Information	No options	Displays CPU information.
CPU Microcode Update Revision	No options	Displays CPU's microcode update revision.
CPU Stepping Signature	No options	Displays CPU's stepping revision.

**Based on the BIOS used by the Intel DB815EEA motherboard. Used by permission of Intel Corporation.*

Note that most newer Intel processors are designed to allow operation only at or below their rated speeds (a feature called *speed locking*), whereas others allow higher-than-rated speeds to be selected.

If a user forgets his password, all he has to do is set the configuration jumper, enter the Maintenance menu in BIOS Setup, and use the option provided to clear the password. This function doesn't tell the user what the password was; it simply clears it, allowing a new one to be set if desired. This means the security is only as good as the lock on the system case because anybody who can get to the configuration jumper can clear the password and access the system. This is why most better cases come equipped with locks.

Extended Configuration Submenu

The Extended Configuration submenu on some Intel motherboards has memory setup options similar to those found in the section "Additional Advanced Features," later in this chapter. See this section for details.

Main Menu

The standard CMOS Setup menu dates back to the 286 days, when the complete BIOS Setup consisted of only one menu. In the standard menu, you can set the system clock and record hard disk and floppy drive parameters and the basic video type. Newer BIOSes have more complicated setups with more menus and submenus, so the main menu often is fairly sparse compared to older systems.

The main menu in a modern system reports system information such as the BIOS version, the processor type and speed, the amount of memory, and whether the memory or cache is configured for ECC functionality. The main menu also can be used to set the system date and time.

Table 5.10 shows a typical main menu.

Table 5.10 Typical Main Menu Settings*

Feature	Options	Description
BIOS Version	No options	Displays the version of the BIOS
Processor Type	No options	Displays the processor type
Processor Speed	No options	Displays the processor speed
System Bus Frequency	No options	Displays the system bus frequency
Cache RAM	No options	Displays the size of second-level (L2) cache and whether it is ECC capable
Total Memory	No options	Displays the total amount of RAM on the motherboard
Memory Bank 0 Memory Bank 1 Memory Bank 2	No options	Displays size and type of DIMM installed in each memory bank
Language	English (default) Deutch Espanol	Selects the default language used by the BIOS
Processor Serial Number	Disabled (default), enabled	Enables/disables processor serial number (present only when a Pentium III CPU is installed)
System Time	Hour, minute, second	Specifies the current time
System Date	Month, day, year	Specifies the current date

**Based on the BIOS used by the Intel D815EEA motherboard. Used by permission of Intel Corporation.*

Some motherboards might also offer the options shown in Table 5.11.

Table 5.11 Additional Main Menu Memory Settings

Feature	Options	Description
ECC Configuration	Non-ECC (default) ECC	Specifies ECC memory operation.
L2 cache ECC Support	Disabled (default) Enabled	Enabled allows error checking to occur on data accessed from L2 cache. This option does not appear when using processors that have L2 cache ECC permanently enabled.

ECC stands for error correcting code, which is the use of extra bits on the memory modules to detect and even correct memory errors on-the-fly. For ECC to be enabled, more expensive ECC DIMMs would have to be installed in the system. Note that all DIMMs would need to be ECC versions for this to work; if only one is non-ECC, ECC can't be enabled. I highly recommend purchasing ECC memory and enabling this function because it makes the system much more fault tolerant and prevents corrupted data due to soft errors in memory. Random memory errors occur at the rate of 1 bit error per month for every 64–256 megabytes installed. ECC ensures that these errors don't creep into your data files, corrupt the system, or cause it to crash.

▶▶ See "Error Correcting Code," p. 449.

Be sure to check and see whether your motherboard supports ECC memory before making a purchase. You can install ECC memory in a non-ECC capable board, but the ECC functions will not work. Also make sure you are aware of the memory requirements for your board. Don't try to install more memory than the board supports, and be sure the modules you use meet the specifications required by the board. See the documentation for the motherboard for more information on the type and amount of memory that can be installed.

Most older BIOSes report memory as base and extended memory instead of as a single value. Base memory is typically 640KB and sometimes is called *conventional* memory. Extended memory is that which is beyond the first megabyte in the system.

You can't change any values in the memory fields; they are only for your information because they are automatically counted up by the system. If the memory count doesn't match what you have installed, a problem has likely occurred with some of the memory: It is defective, not fully seated or properly installed, or it is a type that is incompatible with your system.

Advanced Menu

The Advanced menu is for setting advanced features that are available through the motherboard chipset. This part of your BIOS setup is specific to the particular chipset the motherboard uses. Many chipsets are available on the market today, and each has unique features. The chipset setup is designed to enable the user to customize these features and control some of the chipset settings. Right now, one of the most popular chipsets is the Intel 815E chipset. Table 5.12 shows the typical BIOS chipset settings for a board with a 815E chipset.

Table 5.12 Typical Advanced Menu Settings*

Feature	Options	Description
Extended Configuration	No options	If `Used` is displayed, User-defined has been selected in the Extended Configuration under the Maintenance menu.
PCI Configuration	No options	Configures the IRQ priority of individual PCI slots. When selected, displays the PCI Configuration submenu.

Table 5.12 Continued

Feature	Options	Description
Boot Settings Configuration	No options	Configures Numlock and Plug and Play, and resets configuration data. When selected, displays the Boot Configuration submenu.
Peripheral Configuration	No options	Configures peripheral ports and devices. When selected, displays the Peripheral Configuration submenu.
IDE Configuration	No options	Specifies type of connected IDE device.
Diskette Configuration	No options	When selected, displays the Diskette Configuration submenu.
Event Log	No options	Configures Event Logging. When selected, displays the Event Log Configuration submenu.
Video Configuration	No options	Configures video features. When selected, displays the Video Configuration submenu.

**Based on the BIOS used by the Intel DB815EEA motherboard. Used by permission of Intel Corporation.*

Motherboards based on the 440BX chipset also offer options such as those listed in Table 5.13.

Table 5.13 Additional Advanced Menu Settings*

Feature	Options	Description
Plug and Play O/S	No (default), Yes	Specifies whether a Plug and Play operating system is being used. No—lets the BIOS configure all devices. Yes—lets the operating system configure Plug and Play devices. Not required with a Plug and Play operating system.
Reset Configuration Data	No (default), Yes	Clears the Plug and Play BIOS configuration data on the next boot.
Numlock	Auto (default), On, Off	Specifies the power-on state of the Num Lock feature on the numeric keypad of the keyboard.
Resource Configuration	No options	Configures memory blocks and IRQs for legacy ISA devices. When selected, displays the Resource Configuration submenu.

**Based on the BIOS used by the Intel SE440BX-2 motherboard. Used by permission of Intel Corporation.*

The Plug and Play OS setting is important mainly if you are not using a plug-and-play operating system, such as Windows NT. In that case, you should set that function to No, which enables the Plug and Play BIOS to configure the devices.

Even if this function were set to No, if a plug-and-play operating system, such as Windows 95/98 or Windows 2000, were used, the operating system would override and reconfigure any settings configured by the BIOS. To speed system boot time, if a plug-and-play operating system is being used, you can set this function to Yes, which eliminates the BIOS configuration step.

The Reset Configuration Data setting is a one-time setting that causes the ESCD (enhanced system configuration data) plug-and-play data stored in CMOS RAM to be wiped out at the next boot time. The setting defaults back to No after the next boot. This is useful if the settings in CMOS don't match those stored in the cards themselves, which can happen, for example, if a previously configured card is moved from one system to another or even from one slot to another in the same system. This can cause the Plug and Play BIOS to become confused; resetting the plug-and-play data in CMOS helps clear up this type of problem.

PCI Configuration Submenu

The PCI Configuration submenu is used to select the IRQ priority of add-on cards plugged into the PCI slots. Auto (the default) should be used to allow the BIOS and operating system to assign IRQs to each slot unless specific PCI cards require unique IRQs. See Table 5.14 for a typical example.

Table 5.14 Typical PCI Configuration Submenu Settings*

Feature	Options	Description
PCI Slot 1 IRQ Priority	Auto (default), 9, 10, 11	Allows selection of IRQ priority.
PCI Slot 2 IRQ Priority	Auto (default), 9, 10, 11	Allows selection of IRQ priority.
PCI Slot 3 IRQ Priority	Auto (default), 9, 10, 11	Allows selection of IRQ priority. IRQ priority selections for PCI slot 3 and PCI slot 5 are linked; the options selected for PCI slot 3 are repeated for PCI slot 5.
PCI Slot 4 IRQ Priority	Auto (default), 9, 10, 11	Allows selection of IRQ priority.
PCI Slot 5 IRQ Priority	No options	Always set to Auto (matches settings for PC slot #3).

**Based on the BIOS used by the Intel DB815EEA motherboard. Used by permission of Intel Corporation.*

Boot Configuration Submenu

The options in Table 5.15 configure the system's PnP and keyboard configuration during initial boot.

Table 5.15 Typical Boot Configuration Submenu Settings*

Feature	Options	Description
Plug and Play O/S	No (default), Yes	Specifies whether a plug-and-play operating system is being used. No—Lets the BIOS configure all devices. Appropriate when using a PnP operating system. Yes—Lets the operating system configure Plug and Play devices.
Reset Config Data	No (default), Yes	Yes clears the PnP/PCI BIOS configuration data stored in flash memory on the next boot.
Numlock	On (default), Off	Specifies the power-on state of the Num Lock feature on the numeric keypad of the keyboard.

**Based on the BIOS used by the Intel DB815EEA motherboard. Used by permission of Intel Corporation.*

Additional Advanced Features

Many boards differ in the advanced chipset menus. In most cases, unless you know exactly which chipset and what type of memory and other items are found in your system, it is best to leave these settings on Auto. In that case, the modern boards use the configuration ROM found on the DIMM or RIMM memory modules to properly configure the memory settings. In fact, many newer boards no longer allow these settings to be manually adjusted because, in most cases, all that does is lead to trouble in the form of an unstable or a failing system. If you do want to play with these settings, I recommend first finding out exactly which memory modules and chipset you have and contacting the manufacturers of them to get their databooks. The databooks have all the technical information related to those devices.

Table 5.16 lists some additional settings you might find on some boards. Options found on the Intel DB815EEA motherboard's Extended Configuration submenu are marked with an * in Table 5.16.

Table 5.16 Additional Advanced Features Settings

Setting	Description
Auto Configuration*	Selects predetermined optimal values of chipset parameters. When Disabled, chipset parameters revert to setup information stored in CMOS. Many fields in this screen are not available when Auto Configuration is Enabled.
EDO DRAM Speed Selection	The value in this field must correspond to the speed of the EDO DRAM installed in your system. This value is access speed, so a lower value means a faster system.
SDRAM RAS-to-CAS Delay*	This field lets you control the number of cycles between a row activate command and a read or write command.
SDRAM RAS Precharge Time*	The precharge time is the number of cycles it takes for the RAS to accumulate its charge before DRAM refresh. If insufficient time is allowed, refresh might be incomplete, and the DRAM might fail to retain data.
SDRAM CAS Latency Time*	When synchronous DRAM is installed, you can control the number of cycles between when the SDRAMs sample a read command and when the controller samples read data from the SDRAMs.
SDRAM Precharge Control	When Enabled, all CPU cycles to SDRAM result in an `All Banks Precharge` command on the SDRAM interface.
DRAM Data Integrity Mode	Select Non-ECC or ECC (error correcting code) according to the type of installed DRAM. ECC allows for single-bit error correction and multibit error detection at a slight speed penalty to the system.
System BIOS Cacheable	Allows caching of the system BIOS ROM at F0000h–FFFFFh, resulting in better system performance. If any program writes to this memory area, a system error can result.
Video BIOS Cacheable	Allows caching of the video BIOS ROM at C0000h–C7FFFh, resulting in better video performance. If any program writes to this memory area, a system error can result.
Video RAM Cacheable* (Video Memory Cache Mode)	Selecting Enabled allows caching of the video memory (RAM) at A0000h–AFFFFh, resulting in better video performance. If any program writes to this memory area, a memory access error can result. Uncacheable Speculative Write-Combining (USWC) mode is the same as Enabled on some systems.
8/16 Bit I/O Recovery Time	The I/O recovery mechanism adds bus clock cycles between PCI-originated I/O cycles to the ISA bus. This delay takes place because the PCI bus is so much faster than the ISA bus.
Memory Hole at 15M–16M	Places a 1MB empty RAM area between 15MB and 16MB. Older software sometimes would not run with 16MB or more memory in the system; enabling this provides a workaround. This is normally not used.
Passive Release	When Enabled, CPU-to-PCI bus accesses are allowed during passive release. Otherwise, the arbiter accepts only another PCI master access to local DRAM.
Delayed Transaction	The chipset has an embedded 32-bit posted write buffer to support delay transactions cycles. Select Enabled to support compliance with PCI specification version 2.1.
AGP Aperture Size (MB)	Select the size of the accelerated graphics port (AGP) aperture. The aperture is a portion of the PCI memory address range dedicated for graphics memory address space. Host cycles that hit the aperture range are forwarded to the AGP without any translation.

Table 5.16 Continued

Setting	Description
CPU Warning Temperature	Select the combination of lower and upper limits for the CPU temperature if your computer contains an environmental monitoring system. If the CPU temperature extends beyond either limit, any warning mechanism programmed into your system is activated.
Current CPU Temperature	This field displays the current CPU temperature if your computer contains an environmental monitoring system.
Shutdown Temperature	Select the combination of lower and upper limits for the system shutdown temperature if your computer contains an environmental monitoring system. If the temperature extends beyond either limit, the system shuts down.
CPUFAN Turn On IN Win98	If you are running Windows 98, which supports ACPI, selecting Enabled gives the user a cooling choice at runtime. The user can run with the CPU fan turned on or off, depending on deciding factors such as CPU activity, battery power consumption, and noise tolerance.
Current System Temperature	This field displays the current system temperature if your computer contains a monitoring system.
Current CPUFAN 1/2/3 Speed	These fields display the current speed of up to three CPU fans if your computer contains a monitoring system.
IN0-IN6(V)	These fields display the current voltage of up to seven voltage input lines if your computer contains a monitoring system.
Spread Spectrum	When the system clock generator pulses, the extreme values of the pulse generate excess EMI. Enabling pulse spectrum spread modulation changes the extreme values from spikes to flat curves, thus reducing EMI. This benefit in some cases might be outweighed by problems with timing-critical devices, such as a clock-sensitive SCSI device.

Peripheral Configuration

The Peripheral Configuration menu is used to configure the devices built into the motherboard, such as serial ports, parallel ports, and built-in audio and USB ports.

Table 5.17 shows a typical Peripheral Configuration menu and choices.

Table 5.17 Typical Peripheral Configuration Menu*

Feature	Options	Description
Serial port A	Disabled Enabled Auto (default)	Configures serial port A. Auto-assigns the first free COM port (normally COM 1), the address 3F8h, and the interrupt IRQ4. An asterisk (*) displayed next to an address indicates a conflict with another device.
Base I/O address	3F8 (default) 2F8 3E8 2E8	Specifies the base I/O address for serial port A.
Interrupt	IRQ 3 IRQ 4 (default)	Specifies the interrupt for serial port A.

Table 5.17 Continued

Feature	Options	Description
Serial port B	Disabled Enabled Auto (default)	Configures serial port B. Auto-assigns the first free COM port (normally COM 2), the address 2F8h, and the interrupt IRQ3. An asterisk (*) displayed next to an address indicates a conflict with another device. If either serial port address is set, that address will not appear in the list of options for the other serial port.
Mode	Normal (default) IrDA-SIR ASK_IR	Specifies the mode for serial port B for normal (COM 2) or infrared applications.
Base I/O address	2F8 (default) 3E8 2E8	Specifies the base I/O address for serial port B.
Interrupt	IRQ 3 (default) IRQ 4	Specifies the interrupt for serial port B.
Parallel port	Disabled Enabled Auto (default)	Configures the parallel port. Auto-assigns LPT1 the address 378h and the interrupt IRQ7. An asterisk (*) displayed next to an address indicates a conflict with another device.
Mode	Output Only Bidirectional (default) EPP, ECP	Selects the mode for the parallel port. Output Only operates in AT-compatible mode. Bidirectional operates in bidirectional PS/2-compatible mode. EPP is Extended Parallel Port mode, a high-speed bidirectional mode. ECP is Enhanced Capabilities Port mode, a high-speed bidirectional mode. (EPP and ECP are IEEE-1284–compliant modes and require the use of an IEEE-1284–compliant printer cable.)
Base I/O address	378 (default) 278	Specifies the base I/O address for the parallel port.
Interrupt	IRQ 5 IRQ 7 (default)	Specifies the interrupt for the parallel port.
DMA Channel	DMA 1 DMA 3 (default)	Specifies DMA channel for parallel port (available only when ECP mode is selected).
Audio	Disabled Enabled (default)	Enables or disables the onboard audio subsystem.
LAN	Disabled Enabled (default)	Enables or disables the onboard LAN (network card) device.
Legacy USB Support	Disabled Enabled Auto (default)	Enables or disables USB legacy support. USB legacy support enables support for USB keyboards and mice even though no operating system drivers have been loaded.

**Based on the BIOS used by the Intel DB815EEA motherboard. Used by permission of Intel Corporation.*

I recommend disabling serial and parallel ports if they are not being used because this frees up those resources (especially interrupts that are in high demand) for other devices.

Legacy USB support means support for USB keyboards and mice. If you are using USB keyboards and mice, you will find that the keyboard is not functional until a USB-aware operating system is loaded. This can be a problem when running DOS, diagnostics software, or other applications that run outside of USB-aware operating systems, such as Windows 98, Windows Me, Windows XP, and Windows 2000. In that case, you should enable the USB legacy support via this menu.

Even with legacy support disabled, the system still recognizes a USB keyboard and enables it to work during the POST and BIOS Setup. With USB legacy support in the default (disabled) mode, the system operates as follows:

1. When you power up the computer, USB legacy support is disabled.
2. POST begins.
3. USB legacy support is temporarily enabled by the BIOS. This enables you to use a USB keyboard to enter the setup program or the Maintenance mode.
4. POST completes and disables USB legacy support (unless it was set to Enabled while in Setup).
5. The operating system loads. While the operating system is loading, USB keyboards and mice are not recognized. After the operating system loads the USB drivers, the USB devices are recognized.

To install an operating system that supports USB, enable USB legacy support in BIOS Setup and follow the operating system's installation instructions. After the operating system is installed and the USB drivers are configured, USB legacy support is no longer used, and the operating system USB drivers take over. However, I recommend that you leave legacy support enabled so the USB keyboard functions in DOS while running self-booting or DOS-based diagnostics, or when running other non–USB-aware operating systems.

Note that if USB legacy support is enabled, you shouldn't mix USB and PS/2 port keyboards and mice. For example, don't use a PS/2 keyboard with a USB mouse or a USB keyboard and a PS/2 mouse. Also remember that this legacy support is for keyboards and mice only; it won't work for USB hubs or other USB devices. For devices other than keyboards or mice to work, you need a USB-aware operating system with the appropriate USB drivers.

IDE Configuration Submenu

The IDE Configuration submenu is for configuring IDE devices, such as hard drives, CD-ROM drives, LS-120 (SuperDisk) drives, tape drives, and so on. Table 5.18 shows the IDE Configuration menu and options for a typical modern motherboard.

Table 5.18 Typical IDE Configuration Menu Settings*

Feature	Options	Description
IDE Controller	Disabled Primary Secondary Both (default)	Specifies the integrated IDE controller. Primary enables only the Primary IDE controller. Secondary enables only the Secondary IDE controller. Both enables both IDE controllers.
Hard Disk Pre-Delay	Disabled (default) 3 Seconds 6 Seconds 9 Seconds 12 Seconds 15 Seconds 21 Seconds 30 Seconds	Specifies the hard disk drive pre-delay.

Table 5.18 Continued

Feature	Options	Description
Primary IDE Master	No options	Reports type of connected IDE device. When selected, displays the Primary IDE Master submenu.
Primary IDE Slave	No options	Reports type of connected IDE device. When selected, displays the Primary IDE Slave submenu.
Secondary IDE Master	No options	Reports type of connected IDE device. When selected, displays the Secondary IDE Master submenu.
Secondary IDE Slave	No options	Reports type of connected IDE device. When selected, displays the Secondary IDE Slave submenu.

**Based on the BIOS used by the Intel DB815EEAmotherboard. Used by permission of Intel Corporation.*

The hard disk pre-delay function is to delay accessing drives that are slow to spin up. Some drives aren't ready when the system begins to look for them during boot, causing the system to display Fixed Disk Failure messages and fail to boot. Setting this delay allows time for the drive to become ready before continuing the boot. Of course, this slows down the boot process, so if your drives don't need this delay, it should be disabled.

IDE Configuration Submenus

These submenus are for configuring each IDE device, including primary and secondary masters and slaves.

Of all the BIOS Setup menus, the hard disk settings are by far the most important. In fact, they are the most important of all the BIOS settings. Most modern motherboards incorporate two IDE controllers that support up to four drives. Most modern BIOSes have an autodetect feature that enables automatic configuration of the drives. If this is available, in most cases you should use it because it will prevent confusion in the future. With the Auto setting, the BIOS sends a special Identify Drive command to the drive, which responds with information about the correct settings. From this, the BIOS can automatically detect the specifications and optimal operating mode of almost all IDE hard drives. When you select type Auto for a hard drive, the BIOS redetects the drive specifications during POST, every time the system boots. You could swap drives with the power off, and the system would automatically detect the new drive the next time it was turned on.

In addition to the Auto setting, most older BIOSes offered a standard table of up to 47 drive types with specifically prerecorded parameters. Each defined drive type has a specified number of cylinders, number of heads, write precompensation factor, landing zone, and number of sectors. This often was used many years ago, but it is rarely used today because virtually no drives conform to the parameters on these drive type lists.

Another option is to select a setting called User or User Defined, which is where you can enter the specific drive CHS (Cylinder, Head, and Sector) parameters into the proper fields. These parameters are saved in the CMOS RAM and reloaded every time the system is powered up.

Most BIOSes today offer control over the drive translation settings if the type is set to User and not Auto. Usually, two translation settings are available, called Standard and LBA. Standard or LBA-disabled is used only for drives of 528MB or less, where the maximum number of cylinders, heads, and sectors are 1,024, 16, and 63, respectively. Because most drives today are larger, this setting is rarely used.

LBA (logical block addressing) is used for virtually all drives that are larger than 528MB. Note that systems dating from 1997 and earlier usually are limited to a maximum drive size of 8.4GB unless they have a BIOS upgrade. Systems from 1998 and later usually support drives up to 136.9GB. During drive accesses, the IDE controller transforms the data address described by sector, head, and cylinder number into a physical block address, significantly improving data transfer rates.

Table 5.19 shows the IDE drive settings found in a typical modern motherboard BIOS.

Table 5.19 Typical IDE Drive Settings*

Feature	Options	Description
Type	None ATAPI Removable Other ATAPI CD-ROM User IDE Removable Auto (default)	Specifies the IDE Configuration mode for IDE devices. Auto automatically fills in the transfer mode values. Other options are device dependent.
Maximum Capacity	No options	Reports the maximum capacity for the hard disk.
LBA Mode Control	Disabled Enabled	Enables or disables the LBA mode control.
Multi-Sector Transfers	Disabled 2 Sectors 4 Sectors 8 Sectors 16 Sectors (default)	Specifies number of sectors per block for transfers from the hard drive to memory. Check the hard drive's specifications for optimum setting.
PIO Mode	Auto (default) 0 1 2 3 4	Specifies the PIO mode for moving data to and from the drive.
Ultra DMA Mode	Disabled (default) 0 1 2 3 4 5	Specifies the Ultra DMA mode for moving data to and from the drive.
Cable Detected	No options	Displays the type of cable connected to the IDE interface: 40-conductor or 80-conductor (for Ultra ATA-66/100 devices).

**Based on the BIOS used by the Intel DB815EEA motherboard. Used by permission of Intel Corporation.*

Setting the drive type to Auto causes the other values to be automatically configured correctly. I recommend this for virtually all standard system configurations. When set to Auto, the BIOS sends an Identify command to the drive, causing it to report back all the options and features found on that drive. Using this information, the BIOS then automatically configures all the settings on this menu for maximum performance with that drive, including selecting the fastest possible transfer modes and other features.

For hard drives, the only option available other than Auto is User. When set to User, the other choices are made available and are not automatically set. This can be useful for somebody who wants to "play" with these settings, but in most cases, all you will get by doing so is lower performance and possibly even trouble in the form of corrupted data or a nonfunctional drive.

Diskette Configuration Submenu

The Diskette Configuration submenu is for configuring the floppy drive and interface. Table 5.20 shows the options in a typical BIOS Setup.

Table 5.20 Typical Diskette Configuration Settings*

Feature	Options	Description
Diskette Controller	Disabled Enabled (default)	Disables or enables the integrated diskette controller
Diskette A:	Disabled 360KB, 5 1/4-inch 1.2MB, 5 1/4-inch 720KB, 3 1/2-inch 1.44MB, 3 1/2-inch (default) 2.88MB, 3 1/2-inch	Specifies the capacity and physical size of floppy disk drive A:
Floppy Write Protect	Disabled (default) Enabled	Disables or enables write protect for floppy disk drive A:

**Based on the BIOS used by the Intel DB815EEA motherboard. Used by permission of Intel Corporation.*

By enabling the write-protect feature, you can disallow writing to floppy disks. This can help prevent the theft of data as well as helping to prevent infecting disks with viruses should they be on the system.

Event Logging

The Event Logging menu is for configuring the System Management (SMBIOS) event logging features. SMBIOS is a DMI-compliant method for managing computers on a managed network. DMI stands for Desktop Management Interface, a special protocol software can use to communicate with the motherboard.

Using SMBIOS, a system administrator can remotely obtain information about a system. Applications such as the Intel LANDesk Client Manager can use SMBIOS to report the following DMI information:

- BIOS data, such as the BIOS revision level
- System data, such as installed peripherals, serial numbers, and asset tags
- Resource data, such as memory size, cache size, and processor speed
- Dynamic data, such as event detection including event detection and error logging

Table 5.21 shows a typical Event Logging menu in BIOS Setup.

Table 5.21 Typical Event Logging Menu*

Feature	Options	Description
Event log	No options	Indicates whether space is available in the event log
Event log validity	No options	Indicates whether contents of the event log are valid
View event log	Press [Enter]	Enables viewing of event log
Clear all event logs	No (default) Yes	Clears the event log after rebooting

Table 5.21 Continued

Feature	Options	Description
Event Logging	Disabled, Enabled (default)	Enables logging of events
Mark events as read	Press [Enter]	Marks all events as read.

**Based on the BIOS used by the Intel DB815EEA motherboard. Used by permission of Intel Corporation.*

Some motherboards with ECC memory support also log ECC events. I find event logging particularly useful for tracking errors such as ECC errors. Using the View Log feature, you can see whether any errors have been detected (and corrected) by the system.

Video Configuration

The Video Configuration menu is for configuring video features. Table 5.22 shows the functions of this menu in a typical modern motherboard BIOS.

Table 5.22 Typical Video Configuration Menu*

Feature	Options	Description
Default Primary Video Adapter	AGP (default) PCI	Selects the type of video card used for the boot display device

**Based on the BIOS used by the Intel DB815-EEA motherboard. Used by permission of Intel Corporation.*

Other motherboards might also include features such as those shown in Table 5.23.

Table 5.23 Additional Video Configuration Menu Options

Feature	Options	Description
Palette Snooping	Disabled (default) Enabled	Controls the capability of a primary PCI graphics controller to share a common palette with an ISA add-in video card
AGP Aperture Size	64MB (default) 256MB	Specifies the aperture size for the AGP video controller
AGP Hardware Detected	No options	Indicates whether AGP 1x, 2x, or 4x AGP card is installed; disables onboard graphics subsystem

The most common use of this menu is to change the primary video device. This is useful under Windows 98 and Windows 2000, which support dual-monitor configurations. Using this feature, you can set either the AGP or PCI video card to be the primary boot device.

Resource Configuration

The Resource Configuration menu is used for configuring the memory and interrupt usage of non–plug-and-play (legacy) ISA bus-based devices on motherboards that have one or more ISA slots. Table 5.24 shows the functions and options found in a typical modern BIOS.

Table 5.24 Typical Resource Configuration Menu*

Feature	Options	Description
Memory Reservation	C800 CBFF Available (default) | Reserved CC00 CFFF Available (default) | Reserved D000 D3FF Available (default) | Reserved D400 D7FF Available (default) | Reserved D800 DBFF Available (default) | Reserved DC00 DFFF Available (default) | Reserved	Reserves specific upper memory blocks for use by legacy ISA devices.
IRQ Reservation	IRQ3 Available (default) | Reserved IRQ4 Available (default) | Reserved IRQ5 Available (default) | Reserved IRQ7 Available (default) | Reserved IRQ10 Available (default) | Reserved IRQ11 Available (default) | Reserved	Reserves specific IRQs for use by legacy ISA devices. An asterisk (*) displayed next to an IRQ indicates an IRQ conflict.

**Based on the BIOS used by the Intel SE440BX-2 motherboard. Used by permission of Intel Corporation.*

Note that these settings are only for legacy (non–plug-and-play) ISA devices. For all Plug and Play ISA devices as well as PCI devices (which are Plug and Play by default), these resources are instead configured by the operating system or by software that comes with the cards.

Setting these resources here does not actually control the legacy ISA device; that usually must be done by moving jumpers on the card. By setting the resource as reserved here, you are telling the Plug and Play operating system that the reserved resources are off-limits, so it won't accidentally set a Plug and Play device to use the same resource as a legacy ISA device. Reserving resources in this manner is sometimes required because the Plug and Play software can't detect all legacy ISA devices and therefore won't know which settings the device might be using.

In a system with no legacy devices, you don't need to reserve any resources via this menu.

Some boards have additional configuration options for the Plug and Play (PnP) BIOS features as well as the PCI bus. These features are largely chipset dependent, but some common examples are shown in Table 5.25.

Table 5.25 Typical PnP and PCI Options*

DMA n Assigned to	When resources are controlled manually, assign each system DMA channel as one of the following types, depending on the type of device using the interrupt: ■ Legacy ISA devices compliant with the original PC AT bus specification, requiring a specific DMA channel ■ PCI/ISA PnP devices compliant with the Plug and Play standard, whether designed for PCI or ISA bus architecture

Table 5.25 Continued

PCI IRQ Activated by	Leave the IRQ trigger set at Level unless the PCI device assigned to the interrupt specifies edge-triggered interrupts.
PCI IDE IRQ Map to	This field enables you to select PCI IDE IRQ mapping or PC AT (ISA) interrupts. If your system does not have one or two PCI IDE connectors on the system board, select values according to the type of IDE interface(s) installed in your system (PCI or ISA). Standard ISA interrupts for IDE channels are IRQ14 for primary and IRQ15 for secondary.
Primary/Secondary IDE INT#	Each PCI peripheral connection is capable of activating up to four interrupts: INT# A, INT# B, INT# C, and INT# D. By default, a PCI connection is assigned INT# A. Assigning INT# B has no meaning unless the peripheral device requires two interrupt services rather than just one. Because the PCI IDE interface in the chipset has two channels, it requires two interrupt services. The primary and secondary IDE INT# fields default to values appropriate for two PCI IDE channels, with the primary PCI IDE channel having a lower interrupt than the secondary. Note that all single-function PCI cards normally use INT# A, and each of these must be assigned to a different and unique ISA interrupt request.
Used Mem base addr	Select a base address for the memory area used by any peripheral that requires high memory.
Used Mem Length	Select a length for the memory area specified in the previous field. This field does not appear if no base address is specified.
Assign IRQ for USB	Select Enabled if your system has a USB controller and you have one or more USB devices connected. If you are not using your system's USB controller, select Disabled to free the IRQ resource.

**Based on the BIOS used by the Intel SE440BX-2 motherboard. Used by permission of Intel Corporation.*

Security Menu

Most BIOSes include two passwords for security, called the supervisor and user passwords. These passwords help control who is allowed to access the BIOS Setup program and who is allowed to boot the computer. The supervisor password is also called a setup password because it controls access to the setup program. The user password is also called a system password because it controls access to the entire system.

If a supervisor password is set, a password prompt is displayed when an attempt is made to enter the BIOS Setup menus. When entered correctly, the supervisor password gives unrestricted access to view and change all the Setup options in the Setup program. If the supervisor password is not entered or is entered incorrectly, access to view and change Setup options in the Setup program is restricted.

If the user password is set, the password prompt is displayed before the computer boots up. The password must be entered correctly before the system is allowed to boot. Note that if only the supervisor password is set, the computer boots without asking for a password because the supervisor password controls access only to the BIOS Setup menus. If both passwords are set, the password prompt is displayed at boot time, and either the user or the supervisor password can be entered to boot the computer. In most systems, the password can be up to seven or eight characters long.

If you forget the password, most systems have a jumper on the board that allows all passwords to be cleared. This means that for most systems, the password security also requires that the system case be locked to prevent users from opening the cover and accessing the password-clear jumper. This jumper is often not labeled on the board for security reasons, but it can be found in the motherboard or system documentation.

Provided you know the password and can get into the BIOS Setup, a password can also be cleared by entering the BIOS Setup and selecting the Clear Password function. If no Clear function is available, you can still clear the password by selecting the Set Password function and pressing Enter (for no password) at the prompts.

Table 5.26 shows the security functions in a typical BIOS Setup.

Table 5.26 Typical Security Settings*

Feature	Options	Description
User Password Is	No options.	Reports whether a user password is set.
Supervisor Password Is	No options.	Reports whether a supervisor password is set.
Set User Password	Password can be up to seven alphanumeric characters.	Specifies the user password.
Set Supervisor Password	Password can be up to seven alphanumeric characters.	Specifies the supervisor password.
Clear User Password	No options.	Clears the user password.
User Setup Access	None View Only Limited Access Full Access (default).	Controls the user's capability to run the BIOS Setup program.
Unattended Start	Disabled (default) Enabled.	Enables the unattended start feature. When enabled, the computer boots, but the keyboard is locked. The user must enter a password to unlock the computer or boot from a disk.

**Based on the BIOS used by the Intel DB815EEA motherboard. Used by permission of Intel Corporation.*

To clear passwords if the password is forgotten, most motherboards have a password-clear jumper or switch. Intel motherboards require that you set the configuration jumper, enter the Maintenance menu in BIOS Setup, and select the Clear Password feature. If you can't find the documentation for your board and aren't sure how to clear the passwords, you can try removing the battery for 15 minutes or so, which clears the CMOS RAM. It can take that long for the CMOS RAM to clear on some systems because they have capacitors in the circuit that retain a charge. Note that this also erases all other BIOS settings, including the hard disk settings, so they should be recorded beforehand.

Power Management Menu

Power management is defined as the capability of the system to automatically enter power-conserving modes during periods of inactivity. Two main classes of power management exist; the original standard was called Advanced Power Management (APM) and was supported by most systems since the 386 and 486 processors. More recently, a new type of power management called Advanced Configuration and Power Interface (ACPI) has been developed and began appearing in systems during 1998. Most systems sold in 1998 or later support the more advanced ACPI type of power management. In APM, the hardware does the actual power management, and the operating system or other software had little control. With ACPI, the power management is now done by the operating system and BIOS, and not the hardware. This makes the control more centralized and easier to access and enables applications to work with the power management.

Table 5.27 shows the typical power settings found in most motherboard BIOSes.

Table 5.27 Typical Power Settings*

Feature	Options	Description
Power Management	Disabled Enabled (default)	Enables or disables the BIOS power-management feature.
Inactivity Timer	Off 1 Minute 5 Minutes 10 Minutes 20 Minutes (default) 30 Minutes 60 Minutes 120 Minutes	Specifies the amount of time before the computer enters Standby mode.
Hard Drive	Disabled Enabled (default)	Enables power management for hard disks during Standby and Suspend modes.
ACPI Suspend State	S1 (default) S3	Specifies the ACPI suspend state. S3 is Suspend to RAM; S1 is the default because it is compatible with USB devices that aren't ACPI compliant.
Video Repost Enable	Disable (default)	Allows video BIOS to be initialized coming out of the S3 state; required by some video controllers. This option is listed only if ACPI suspend state is set as S3.

**Based on the BIOS used by the Intel DB815EEA motherboard. Used by permission of Intel Corporation.*

When in Standby mode, the BIOS reduces power consumption by spinning down hard drives and reducing power to or turning off monitors that comply with Video Electronics Standards Organization (VESA) and Display Power Management Signaling (DPMS). While in Standby mode, the system can still respond to external interrupts, such as those from keyboards, mice, fax/modems, or network adapters. For example, any keyboard or mouse activity brings the system out of Standby mode and immediately restores power to the monitor.

In most systems, the operating system takes over most of the power management settings, and in some cases, it can even override the BIOS settings. This is definitely true if the operating system and motherboard both support ACPI.

Some systems feature additional power management settings in their BIOSes. Some of the more common ones are shown in Table 5.28.

Table 5.28 Typical Power Management Settings*

ACPI Function	Select Enabled only if your computer's operating system supports the ACPI specification. Windows 98 and all later versions support ACPI.
Power Management	This option enables you to select the type (or degree) of power saving for Doze, Standby, and Suspend modes. Following are the individual mode settings: Max Saving—Maximum power savings. Inactivity period is one minute in each mode. User Define—Set each mode individually. Select timeout periods in the section for each mode. Min Saving—Minimum power savings. Inactivity period is one hour in each mode (except the hard drive).

Table 5.28 Continued

PM Control by APM	If Advanced Power Management (APM) is installed on your system, selecting Yes gives better power savings.
Video Off Method	Determines the manner in which the monitor is blanked.
V/H SYNC+Blank	System turns off vertical and horizontal synchronization ports and writes blanks to the video buffer.
DPMS Support	Select this option if your monitor supports the DPMS standard of VESA. Use the software supplied for your video subsystem to select video power management values.
Blank Screen	System writes only blanks to the video buffer.
Video Off After	As the system moves from lesser to greater power-saving modes, select the mode in which you want the monitor to blank.
MODEM Use IRQ	Name the IRQ line assigned to the modem (if any) on your system. Activity of the selected IRQ always awakens the system.
Doze Mode	After the selected period of system inactivity, the CPU clock throttles to a small percentage of its duty cycle: between 10% and 25% for most chipsets. All other devices still operate at full speed.
Standby Mode	After the selected period of system inactivity, the CPU clock stops, the hard drive enters an idle state, and the L2 cache enters a power-save mode. All other devices still operate at full speed.
Suspend Mode	After the selected period of system inactivity, the chipset enters a hardware suspend mode, stopping the CPU clock and possibly causing other system devices to enter power-management modes.
HDD Power Down	After the selected period of drive inactivity, any system IDE devices compatible with the ATA-2 specification or later power manage themselves, putting themselves into an idle state after the specified timeout and then waking themselves up when accessed.
Throttle Duty Cycle	When the system enters Doze mode, the CPU clock runs only part of the time. You can select the percentage of time the clock runs.
VGA Active Monitor	When enabled, any video activity restarts the global timer for Standby mode.
Soft-Off by PWR-BTTN	When you select Instant Off or Delay 4 Sec., turning off the system with the On/Off button places the system in a very low power-usage state, either immediately or after 4 seconds, with only enough circuitry receiving power to detect power button activity or Resume by Ring activity.
CPUFAN Off in Suspend	When enabled, the CPU fan turns off during Suspend mode.
Resume by Ring	When enabled, an input signal on the serial Ring Indicator (RI) line (in other words, an incoming call on the modem) awakens the system from a soft off state.
Resume by Alarm	When enabled, you can set the date and time at which the RTC (real-time clock) alarm awakens the system from Suspend mode.
Date (of Month) Alarm	Select a date in the month when you want the alarm to go off.
Time (hh:mm:ss) Alarm	Set the time you want the alarm to go off.
Wake Up On LAN	When enabled, an input signal from a local area network (LAN) awakens the system from a soft off state.
IRQ8 Break [Event From] Suspend	You can select Enabled or Disabled for monitoring of IRQ8 (the real-time clock) so it does not awaken the system from Suspend mode.

Table 5.28 Continued

Reload Global Timer Events	When enabled, an event occurring on each device listed below restarts the global timer for Standby mode: IRQ3-7, 9-15, NMI Primary IDE 0 Primary IDE 1 Secondary IDE 0 Secondary IDE 1 Floppy Disk Serial Port Parallel Port

**Based on the BIOS used by the Intel SE440BX-2 motherboard. Used by permission of Intel Corporation.*

Boot Menu (Boot Sequence, Order)

The Boot menu is used for setting the boot features and the boot sequence. If your operating system includes a bootable CD—Windows 2000, for example—use this menu to change the boot drive order to check your CD before your hard drive. Table 5.29 shows the functions and settings available on a typical motherboard.

Table 5.29 Typical Boot Menu Settings*

Feature	Options	Description
Quiet Boot	Disabled Enabled (default)	Disabled displays normal POST messages; Enabled displays OEM graphic instead.
Intel Rapid BIOS Boot	Disabled Enabled (default)	Enables the computer to boot without running certain POST tests.
Scan User Flash Area	Disabled (default) Enabled	Enables the BIOS to scan the flash memory for user binary files that are executed at boot time.
After Power Failure	Power On Stay Off Last State (default)	Specifies the mode of operation if an AC/Power loss occurs. Power On restores power to the computer. Stay Off keeps the power off until the power button is pressed. Last State restores the previous power state before the power loss occurred.
On Modem Ring	Stay Off Power On (default)	In APM mode only, specifies how the computer responds to an incoming call on an installed modem when the power is off.
On LAN	Stay Off Power On (default)	In APM mode only. Specifies how the computer responds to a LAN wakeup event.
On PME	Stay Off (default) Power On	In APM mode only. Specifies how the computer responds to a PCI power management event.
On ACPI S5	Stay Off (default) Power On	In ACPI mode only. Specifies the action of the system when a LAN wakeup event occurs.
First Boot Device Second Boot Device Third Boot Device Fourth Boot Device	Floppy ARMD-FDD ARMD-HDD IDE-HDD ATAPI CD-ROM Intel UNDi, PXE 2.0 Disabled	Specifies the boot sequence from the available devices. To specify boot sequence, do this: 1. Select the boot device with up or down arrow keys. 2. Press Enter to set the selection as the intended boot device. The operating system assigns a drive letter to each boot device in the order listed. Changing the order of the devices changes the drive lettering.

Table 5.29 Continued

Feature	Options	Description
		The defaults for the first through fifth devices include: ■ Floppy ■ IDE-HDD ■ ATAPI CD-ROM ■ Intel UNDi, PXE 2.0 ■ Disabled ARMD-HDD is an ATAPI removable device hard disk drive. ARMD-FDD is an ATAPI removable devices floppy disk drive (such as an LS-120 SuperDisk or Zip drive). Intel UNDi, PXE 2.0 is available only if the onboard LAN subsystem is present.
IDE Drive Configuration	No options	Configures IDE drives. When selected, displays the IDE Drive Configuration submenu.

**Based on the BIOS used by the Intel DB815EEA motherboard. Used by permission of Intel Corporation.*

Using this menu, you can configure which devices your system boots from and in which order the devices are sequenced. From this menu, you also can access Hard Drive and Removable Devices submenus, which enable you to configure the ordering of these devices in the boot sequence. For example, you can set hard drives to be the first boot choice, and then in the hard drive submenu, decide to boot from the secondary drive first and the primary drive second. Normally, the default with two drives would be the other way around.

Some recent systems also enable you to boot from external USB drives, such as Zip or LS-120 SuperDisk drives.

IDE Drive Configuration Submenu

The IDE Drive Configuration submenu enables you to select the boot order for the IDE drives in your computer. This BIOS option enables you to install more than one bootable hard disk in your computer and select which one you want to boot from at a BIOS level, rather than by using a boot manager program. If you need to work with multiple operating systems, this menu can be very useful. Table 5.30 is an example of a typical IDE Drive Configuration menu.

Table 5.30 IDE Drive Configuration Submenu*

Feature	Options	Description
Primary Master IDE	1st IDE (default) 1–4	Allows you to select the order in which the Primary Master IDE drive boots
Primary Slave IDE	2nd IDE (default) 1–4	Allows you to select the order in which the Primary Slave IDE drive boots
Secondary Master IDE	3rd IDE (default) 1–4	Allows you to select the order in which the Secondary Master IDE drive boots
Secondary Slave IDE	4th IDE (default) 1–4	Allows you to select the order in which the Secondary Slave IDE drive boots

**Based on the BIOS used by the Intel DB815EEA motherboard. Used by permission of Intel Corporation.*

Exit Menu

The Exit menu is for exiting the Setup program, saving changes, and loading and saving defaults. Table 5.31 shows the typical selections found in most motherboard BIOSes.

Table 5.31 Typical Exit Menu Settings*

Feature	Description
Exit Saving Changes	Exits and saves the changes in CMOS RAM.
Exit Discarding Changes	Exits without saving any changes made in Setup.
Load Setup Defaults	Loads the factory default values for all the Setup options.
Load Custom Defaults	Loads the custom defaults for Setup options.
Save Custom Defaults	Saves the current values as custom defaults. Normally, the BIOS reads the Setup values from flash memory. If this memory is corrupted, the BIOS reads the custom defaults. If no custom defaults are set, the BIOS reads the factory defaults.
Discard Changes	Discards changes without exiting Setup. The option values present when the computer was turned on are used.

**Based on the BIOS used by the Intel DB815-EEA motherboard. Used by permission of Intel Corporation.*

After you have selected an optimum set of BIOS Setup settings, you can save them using the Save Custom Defaults option. This enables you to quickly restore your settings if they are corrupted or lost. All BIOS settings are stored in the CMOS RAM memory, which is powered by a battery attached to the motherboard.

Additional BIOS Setup Features

Some systems have additional features in their BIOS Setup screens, which might not be found in all BIOSes. Some of the more common features you might see are shown in Table 5.32.

Table 5.32 Additional BIOS Setup Features

Virus Warning	When enabled, you receive a warning message if a program attempts to write to the boot sector or the partition table of the hard disk drive. If you get this warning during normal operation, you should run an antivirus program to see whether an infection has occurred. This feature protects only the master boot sector, not the entire hard drive. Note that programs which usually write to the master boot sector, such as FDISK, can trigger the virus warning message.
CPU Internal Cache/ External Cache	This allows you to disable the L1 (internal) and L2 (external) CPU caches. This is often used when testing memory, in which case you don't want the cache functioning. For normal operation, both caches should be enabled.
Quick Power On Self Test	When enabled, this reduces the amount of time required to run the POST. A quick POST skips certain steps, such as the memory test. If you trust your system, you can enable the quick POST, but in most cases I recommend leaving it disabled so you get the full-length POST version.
Swap Floppy Drive	This field is functional only in systems with two floppy drives. Selecting Enabled assigns physical drive B: to logical drive A: and physical drive A: to logical drive B:.
Boot Up Floppy Seek	When enabled, the BIOS tests (seeks) floppy drives to determine whether they have 40 or 80 tracks. Only 360KB floppy drives have 40 tracks; drives with 720KB, 1.2MB, and 1.44MB capacity all have 80 tracks. Because very few modern PCs have 40-track floppy drives, you can disable this function to save time.

Table 5.32 Continued

Boot Up System Speed	Select High to boot at the default CPU speed; select Low to boot at a simulated 8MHz speed. The 8MHz option often was used in the past with certain copy-protected programs, which would fail the protection scheme if booted at full speed. This option is not used today.
Gate A20 Option	Gate A20 refers to the way the system addresses memory above 1MB (extended memory). When set to Fast, the system chipset controls Gate A20. When set to Normal, a pin in the keyboard controller controls Gate A20. Setting Gate A20 to Fast improves system speed, particularly with protected-mode operating systems such as Windows 9x and Windows 2000.
Typematic Rate Setting	When disabled, the following two items (Typematic Rate and Typematic Delay) are irrelevant. Keystrokes repeat at a rate determined by the keyboard controller in your system. When enabled, you can select a typematic rate and typematic delay.
Typematic Rate (Chars/Sec)	When the typematic rate setting is enabled, you can select a typematic rate (the rate at which characters repeat when you hold down a key) of 6, 8, 10, 12, 15, 20, 24, or 30 characters per second.
Typematic Delay (Msec)	When the typematic rate setting is enabled, you can select a typematic delay (the delay before key strokes begin to repeat) of 250, 500, 750, or 1,000 milliseconds.
Security Option	If you have set a password, select whether the password is required every time the system boots or only when you enter Setup.
PS/2 Mouse Function Control	If your system has a PS/2 (motherboard) mouse port and you install a serial or USB pointing device, select Disabled.
PCI/VGA Palette Snoop	Allows multimedia boards to read data from video RAM. Normally set to Disabled unless specifically instructed when installing a multimedia board.
HDD S.M.A.R.T. Capability	S.M.A.R.T. is an acronym for Self-Monitoring Analysis and Reporting Technology system. S.M.A.R.T. is a hard drive self-diagnostic feature available on some IDE hard drives. Enabling this option is recommended if you use diagnostic software that can monitor S.M.A.R.T.-compatible drives to warn you of impending failures.
Report No FDD For WIN 95	Select Yes to release IRQ6 when the system contains no floppy drive, for compatibility with Windows 95 logo certification. In the Integrated Peripherals screen, select Disabled for the Onboard FDC Controller field.
ROM Shadowing	ROM chips typically are very slow, around 150ns (nanoseconds), and operate only 8 bits at a time, whereas RAM runs 60ns or even 10ns or less and is either 32 bits or 64 bits wide in most systems. Shadowing is the copying of BIOS code from ROM into RAM, where the CPU can read the BIOS drivers at the higher speed of RAM.
Operating Frequency	Some motherboards enable you to select the FSB (front-side bus) and CPU clock multiplier speeds within the BIOS rather than through the normal motherboard-based DIP switches or jumper blocks. Select this option to enable customized settings for the CPU Clock Multiplier and CPU Frequency options.
CPU Frequency	This option enables you to vary the CPU FSB frequency from the default 66MHz, 100MHz, or 133MHz to higher values, enabling you to overclock your system.
CPU Clock Multiplier	This option enables you to vary the CPU clock multiplier from its default values to higher values **if** the CPU is not multiplier-locked. Recent and current Intel CPUs ignore nonstandard CPU clock multiplier settings, but AMD Athlon and Duron CPUs can be overclocked with this option.
CPU Vcore Setting	This option enables you to vary the core voltage of the CPU to improve the stability of your system during overclocking or to install CPUs not specifically supported by the default Automatic voltage settings.

Year 2000 BIOS Issues

All systems now in use should be compliant with twenty-first century dates, either through BIOS updates or through software or hardware patches. However, if you are returning stored systems built before 1999 to service, you might want to test them for Year 2000 compliance. For details, see *Upgrading and Repairing PCs, 12th Edition*, available in electronic form on the CD-ROM packaged with this book.

Plug and Play BIOS

Traditionally, installing and configuring devices in PCs has been a difficult process. During installation, the user is faced with the task of configuring the new card by selecting the IRQ, I/O ports, and DMA channel. In the past, users were required to move jumpers or set switches on the add-in cards to control these settings. They needed to know exactly which resources were already in use so they could find a set of resources that did not conflict with the devices already in the system. If a conflict exists, the system might not boot and the device might fail or cause the conflicting hardware to fail.

PnP is technology designed to prevent configuration problems and provide users with the capability to easily expand a PC. With PnP, the user simply plugs in the new card and the system configures it automatically for proper operation.

PnP is composed of three principal components:

- Plug and Play BIOS
- Extended System Configuration Data (ESCD)
- Plug and Play operating system

The PnP BIOS initiates the configuration of the PnP cards during the boot-up process. If the cards previously were installed, the BIOS reads the information from ESCD and initializes the cards and boots the system. During the installation of new PnP cards, the BIOS consults the ESCD to determine which system resources are available and needed for the add-in card. If the BIOS is capable of finding sufficient available resources, it configures the card. However, if the BIOS is incapable of locating sufficient available resources, the Plug and Play routines in the operating system complete the configuration process. During the configuration process, the configuration registers (in flash BIOS) on the card and the ESCD are updated with the new configuration data.

PnP Device IDs

All Plug and Play devices must contain a Plug and Play device ID to enable the operating system to uniquely recognize the device so it can load the appropriate driver software. Each device manufacturer is responsible for assigning the Plug and Play ID for each product and storing it in the hardware.

Each manufacturer of Plug and Play devices must be assigned an industry-unique, three-character vendor ID. Then, the device manufacturer is responsible for assigning a unique product ID to each individual product model. After an ID is assigned to a product model, it must not be assigned to any other product model manufactured by the same company (that is, one that uses the same vendor ID).

Note

For a comprehensive, printable list of PnP device IDs, see "PnP Device IDs" in the Technical Reference section of the CD accompanying this book.

ACPI

ACPI stands for Advanced Configuration and Power Interface, which defines a standard method for integrating power management as well as system configuration features throughout a PC, including the hardware, operating system, and application software. ACPI goes far beyond the previous standard, called Advanced Power Management (APM), which consisted mainly of processor, hard disk, and display control. ACPI not only controls power, but also all the Plug and Play hardware configuration throughout the system. With ACPI, system configuration (Plug and Play) as well as power management configuration is no longer controlled via the BIOS Setup; it is controlled entirely within the operating system instead.

ACPI enables the system to automatically turn peripherals on and off (such as CD-ROMs, network cards, hard disk drives, and printers), as well as external devices connected to the PC (such as VCRs, televisions, telephones, and stereos). ACPI technology also enables peripherals to turn on or activate the PC. For example, inserting a tape into a VCR can turn on the PC, which could then activate a large-screen television and high-fidelity sound system.

ACPI enables system designers to implement a range of power management features with various hardware designs while using the same operating system driver. ACPI also uses the Plug and Play BIOS data structures and takes control over the Plug and Play interface, providing an operating-system–independent interface for configuration and control. ACPI is supported in Windows 98/Me, Windows 2000, XP, and later versions.

During the system setup and boot process, Windows versions supporting ACPI perform a series of checks and tests to see whether the system hardware and BIOS supports ACPI. If support for ACPI is either not detected or found to be faulty, the system typically reverts to standard Advanced Power Management control, but problems can also cause a lockup with either a red or blue screen with an ACPI error code.

Red screens indicate that the problem is probably related to hardware or the BIOS. Blue screens indicate that the problem is probably related to software or is an obscure problem. The ACPI error codes are described in Table 5.33.

Table 5.33 ACPI Error Codes

Error Code	Description
1xxx -	Indicates an error during initialization phase of the ACPI driver and usually means the driver can't read one or more of the ACPI tables
2xxx -	Indicates an ACPI machine language (AML) interpreter error
3xxx -	Indicates an error within the ACPI driver event handler
4xxx -	Indicates thermal management errors
5xxx -	Indicates device power management errors

Virtually all these errors are the result of partial or incomplete ACPI implementations or incompatibilities in either the BIOS or device drivers. If you encounter any of these errors, contact your motherboard manufacturer for an updated BIOS or the device manufacturers for updated drivers.

Initializing a PnP Device

One responsibility of a Plug and Play BIOS during POST is to isolate and initialize all Plug and Play cards and assign them with a valid Card Select Number (CSN). After a CSN is assigned, the system BIOS can then designate resources to the cards. The BIOS is responsible only for the configuration of boot devices; all the remaining Plug and Play devices can be configured dynamically by the operating system software.

The following steps outline a typical flow of a Plug and Play BIOS during the POST:

1. Disable all configurable devices.
2. Identify all Plug and Play devices.
3. Construct a resource map of resources that are statically allocated to devices in the system.
4. Enable input and output devices.
5. Perform ISA ROM scan.
6. Configure the boot device.
7. Enable Plug and Play ISA and other configurable devices.
8. Start the bootstrap loader.

If the loaded operating system is Plug and Play compliant, it takes over management of the system resources. Any unconfigured Plug and Play devices are configured by the appropriate system software or the Plug and Play operating system.

At this point, the operating system is loaded and takes control over Plug and Play system resources. Using the Device Manager in the operating system such as Windows, the user can now control any Plug and Play devices.

BIOS Error Messages

When a PC system is first powered on, the system runs a POST. If errors are encountered during the POST, you usually see a text error message displayed onscreen. Errors that occur very early in the POST might happen before the video card is initialized. These types of errors can't be displayed, so the system uses two other alternatives for communicating the error message. One is beeping—the system beeps the speaker in a specific pattern that indicates which error has occurred.

The other alternative is to send a hexadecimal error code to I/O port address 80h, which can be read by a special card in one of the bus slots. When the ROM BIOS is performing the POST, in most systems the results of these tests are continuously sent to I/O Port 80h so they can be monitored by special diagnostics cards called POST cards (see Figure 5.7). These tests sometimes are called *manufacturing tests* because they were designed into the system for testing systems on the assembly line without a video display attached.

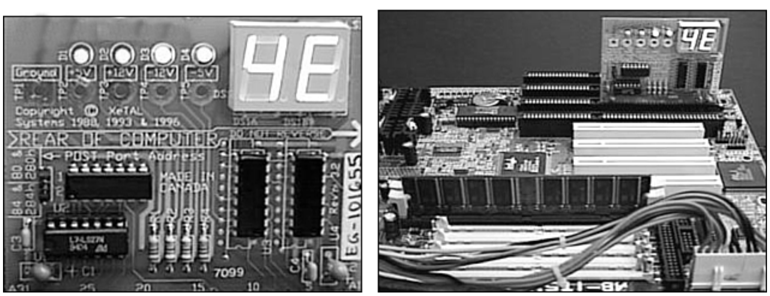

Figure 5.7 A typical POST card with two-digit hexadecimal code display (left) and a POST card in operation (right).

The POST cards have a two-digit hexadecimal display used to report the number of the currently executing test routine. Before executing each test, a hexadecimal numeric code is sent to the port, and then the test is run. If the test fails and locks up the machine, the hexadecimal code of the last test being executed remains on the card's display.

Many tests are executed in a system before the video display card is enabled, especially if the display is EGA or VGA. Therefore, many errors can occur that would lock up the system before the system could possibly display an error code through the video system. Because not all these errors generate beep codes, to most normal troubleshooting procedures, a system with this type of problem (such as a memory failure in Bank 0) would appear completely "dead." By using one of the commercially available POST cards, however, you can often diagnose the problem.

These codes are completely BIOS dependent because the card does nothing but display the codes sent to it. Some BIOSes have more detailed POST procedures and therefore send more informative codes. POST cards can be purchased from JDR Microdevices or other sources and are available in both ISA and PCI bus versions.

For simple but otherwise fatal errors that can't be displayed onscreen, most of the BIOS versions also send audio codes that can be used to help diagnose such problems. The audio codes are similar to POST codes, but they are read by listening to the speaker beep rather than by using a special card.

The following sections detail the text, beep, and I/O port 80h error codes for all the popular BIOS versions.

Note

The CD accompanying this book contains an exhaustive listing of BIOS error codes, error messages, and beep codes for BIOSes from Phoenix, AMI, Award, Microid Research, and IBM.

General BIOS Boot Text Error Messages

The ROM maps of most PCs are similar to the original IBM systems with which they are compatible—with the exception of the Cassette BASIC portion (also called ROM BASIC). It might come as a surprise to some PC users, but the original IBM PC actually had a jack on the rear of the system for connecting a cassette tape recorder. This was to be used for loading programs and data to or from a cassette tape. Tapes were used at the time because floppy drives were very costly, and hard disks were not even an option yet. Floppy drives came down in price quickly at the time, and the cassette port never appeared on any subsequent IBM systems. The cassette port also never appeared on any compatible systems.

The original PC came standard with only 16KB of memory in the base configuration. No floppy drives were included, so you could not load or save files from disks. Most computer users at the time would either write their own programs in the BASIC (beginner's all-purpose symbolic instruction code) language or run programs written by others. A BASIC language interpreter was built into the ROM BIOS of these early IBMs and was designed to access the cassette port on the back of the system.

What is really strange is that IBM kept this ROM BASIC relationship all the way into the early 1990s! I liken this to humans having an appendix. The ROM BASIC in those IBM systems is a sort of vestigial organ—a leftover that had some use in prehistoric ancestors but that has no function today.

You can catch a glimpse of this ROM BASIC on older IBM systems that have it by disabling all the disk drives in the system. In that case, with nothing to boot from, most IBM systems unceremoniously dump you into the strange (vintage 1981) ROM BASIC screen. When this occurs, the message looks like this:

```
The IBM Personal Computer Basic
Version C1.10 Copyright IBM Corp 1981
62940 Bytes free
Ok
```

Many people used to dread seeing this because it usually meant that your hard disk had failed to be recognized! Because no compatible systems ever had the Cassette BASIC interpreter in ROM, they had to come up with different messages to display for the same situations in which an IBM system would invoke this BASIC. Compatibles that have an AMI BIOS in fact display a confusing message, as follows:

```
NO ROM BASIC - SYSTEM HALTED
```

This message is a BIOS error message that is displayed by the AMI BIOS when the same situations occur that would cause an IBM system to dump into Cassette BASIC, which, of course, is not present in an AMI BIOS (or any other compatible BIOS, for that matter). Other BIOS versions display different messages. For example, under the same circumstances, a Compaq BIOS displays the following:

```
Non-System disk or disk error
replace and strike any key when ready
```

This is somewhat confusing on Compaq's part because this very same (or similar) error message is contained in the DOS Boot Sector and would normally be displayed if the system files were missing or corrupted.

In the same situations in which you would see Cassette BASIC on an IBM system, a system with an Award BIOS would display the following:

```
DISK BOOT FAILURE, INSERT SYSTEM DISK AND PRESS ENTER
```

Phoenix BIOS systems display either

```
No boot device available -
strike F1 to retry boot, F2 for setup utility
```

or

```
No boot sector on fixed disk -
strike F1 to retry boot, F2 for setup utility
```

The first or second Phoenix message displays depending on which error actually occurred.

Although the message displayed varies from BIOS to BIOS, the cause is the same for all of them. Two things can generally cause any of these messages to be displayed, and they both relate to specific bytes in the Master Boot Record, which is the first sector of a hard disk at the physical location Cylinder 0, Head 0, Sector 1.

The first problem relates to a disk that has either never been partitioned or that has had the Master Boot Sector corrupted. During the boot process, the BIOS checks the last two bytes in the Master Boot Record (the first sector of the drive) for a “signature” value of 55AAh. If the last two bytes are not 55AAh, an Interrupt 18h is invoked. This calls the subroutine that displays the message you received, and the others indicated, or on an IBM system invokes Cassette (ROM) BASIC.

The Master Boot Sector (including the signature bytes) is written to the hard disk by the DOS FDISK program. Immediately after you low-level format a hard disk, all the sectors are initialized with a pattern of bytes, and the first sector does not contain the 55AAh signature. In other words, these ROM error messages are exactly what you see if you attempt to boot from a hard disk that has been low-level formatted but has not yet been partitioned.

Now consider the second situation that can cause these messages. If the signature bytes are correct, the BIOS executes the Master Partition Boot Record code, which performs a test of the Boot Indicator Bytes in each of the four partition table entries. These bytes are at offset 446 (1BEh), 462 (1CEh), 478 (1DEh), and 494 (1EEh), respectively. They are used to indicate which of the four possible partition table entries contains an active (bootable) partition. A value of 80h in any of these byte offsets indicates that table contains the active partition, whereas all other values must be 00h. If more than one of these bytes is 80h (indicating multiple active partitions), or any of the byte values is anything other than 80h or 00h, you see the following error message:

```
Invalid partition table
```

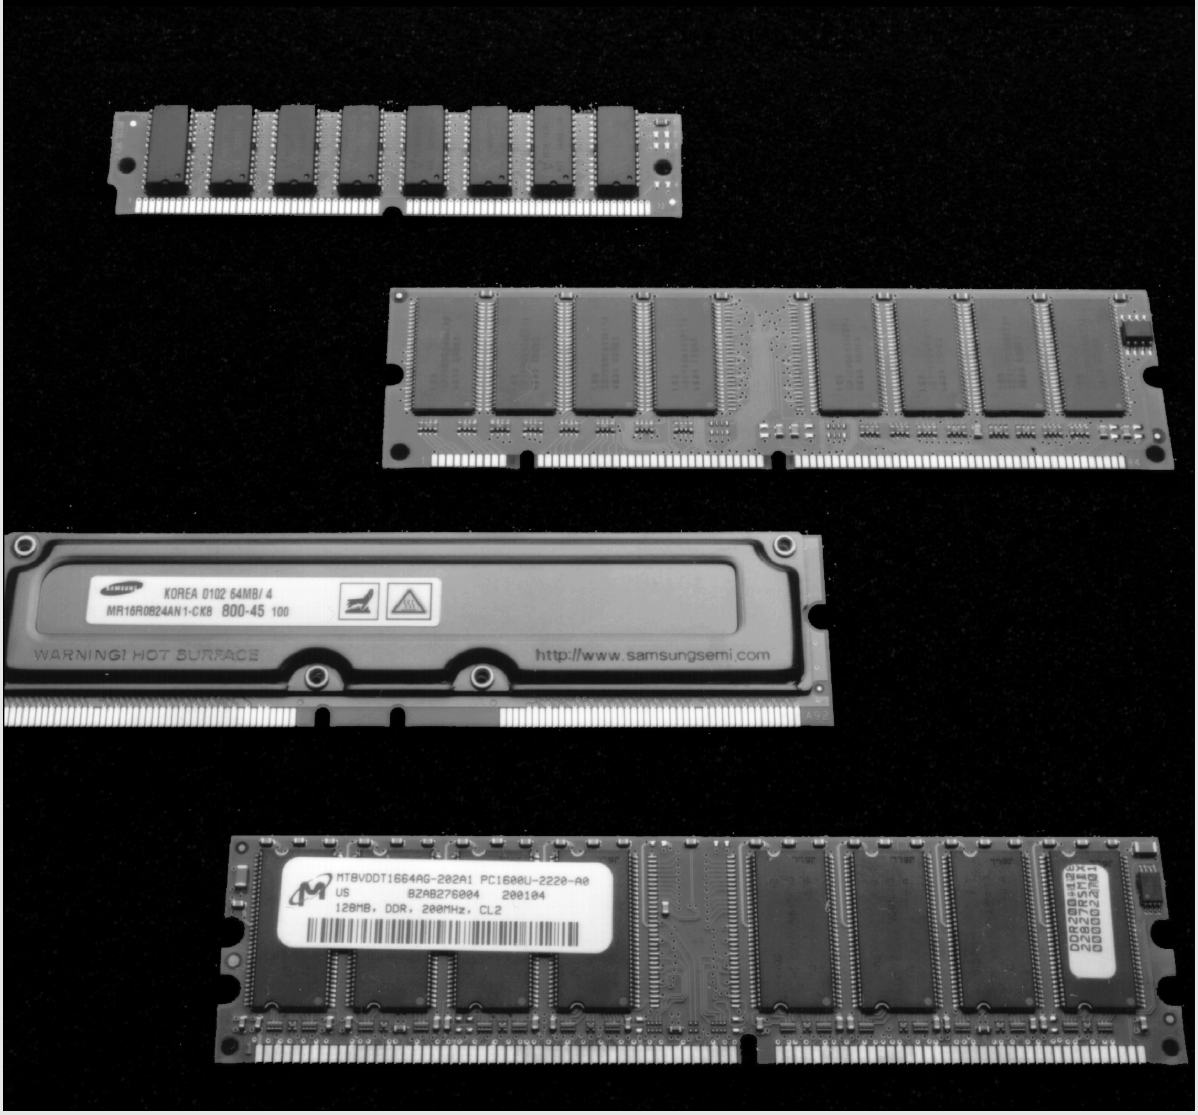
If all these four Boot Indicator Bytes are 00h, indicating no active (bootable) partitions, you also see Cassette BASIC on an IBM system or the other messages indicated earlier, depending on which BIOS you have. This is exactly what occurs if you were to remove the existing partitions from a drive using FDISK but had not created new partitions on the drive, or had failed to make one of the partitions Active (bootable) with FDISK before rebooting your system.

Unfortunately, no easy way exists to clear out the partition table on a system where it is damaged. You can try to use FDISK to remove damaged partitions, but FDISK doesn't always allow it. In that case, you must resort to something more powerful, such as the `DISKEDIT` command found in the Norton Utilities package by Symantec.

The third cause for these errors is tampering with the LBA mode translation in the system BIOS. LBA mode translates the actual disk geometry of the drive into a format that enables the entire disk to be used by DOS and Windows. If a drive is prepared with LBA mode enabled, and LBA mode is then disabled, the BIOS's boot loader will not be capable of locating the Master Boot Record and will display an error similar to those listed previously. Thus, if you see such errors on a system with a hard drive larger than 504MB (or 528 million bytes), be sure to check the LBA mode settings for the drive. On some of the older AMI BIOS Hi-Flex and WinBIOS (graphical) versions, the LBA mode setting is not on the same screen as the hard disk setup but is buried in the Advanced or Built-in Peripherals setup screens where it can be turned off by autoconfiguring BIOS setup options.

CHAPTER 6

Memory



Memory Basics

This chapter looks at memory from both a physical and logical point of view. First, you will look at what memory is, where it fits into the PC architecture, and how it works. Then I'll discuss the various types of memory, speeds, and packaging of the chips and memory modules you can buy and install.

This chapter also covers the logical layout of memory, defining the various areas and their uses from the system's point of view. Because the logical layout and uses are within the "mind" of the processor, memory mapping and logical layout remain perhaps the most difficult subjects to grasp in the PC universe. This chapter contains useful information that removes the mysteries associated with memory and enables you to get the most out of your system.

Memory is the workspace for the computer's processor. It is a temporary storage area where the programs and data being operated on by the processor must reside. Memory storage is considered temporary because the data and programs remain there only as long as the computer has electrical power or is not reset. Before being shut down or reset, any data that has been changed should be saved to a more permanent storage device of some type (usually a hard disk) so it can be reloaded into memory again in the future.

MMemory often is called *RAM*, for *random access memory*. Main memory is called RAM because you can randomly (as opposed to sequentially) access any location in memory. This designation is somewhat misleading and often misinterpreted. Read-only memory (ROM), for example, is also randomly accessible, yet usually is differentiated from the system RAM because it maintains data without power and can't normally be written to. Also, disk memory is randomly accessible, too, but we don't consider that RAM either.

Over the years, the definition of RAM has changed from a simple acronym to become something that means the primary memory workspace used by the processor to run programs, which usually is constructed of a type of chip called Dynamic RAM (DRAM). One of the characteristics of DRAM chips (and therefore RAM in general) is that they store data dynamically, which really has two meanings. One meaning is that the information can be written to RAM over and over again at any time. The other has to do with the fact that DRAM requires the data to be refreshed (essentially rewritten) every 15ms (milliseconds) or so. A type of RAM called Static RAM (SRAM) does not require the periodic refreshing. An important characteristic of RAM in general is that data is stored only as long as the memory has electrical power.

When we talk about a computer's memory, we usually mean the RAM or physical memory in the system, which is primarily the memory chips or modules used by the processor to store primary active programs and data. This often is confused with the term *storage*, which should be used when referring to things such as disk and tape drives (although they can be used as a form of RAM called virtual memory).

RAM can refer to both the physical chips that make up the memory in the system and the logical mapping and layout of that memory. *Logical mapping* and *layout* refer to how the memory addresses are mapped to actual chips and what address locations contain which types of system information.

People new to computers often confuse main memory (RAM) with disk storage because both have capacities that are expressed in similar megabyte or gigabyte terms. The best analogy to explain the relationship between memory and disk storage I've found is to think of an office with a desk and a file cabinet.

In this popular analogy, the file cabinet represents the system's hard disk, where both programs and data are stored for long-term safekeeping. The desk represents the system's main memory, which allows the person working at the desk (acting as the processor) direct access to any files placed on it. Files represent the programs and documents you can "load" into the memory. To work on a particular file, it must first be retrieved from the cabinet and placed on the desk. If the desk is large enough, you might be able to have several files open on it at one time; likewise, if your system has more memory, you can run more or larger programs and work on more or larger documents.

Adding hard disk space to a system is like putting a bigger file cabinet in the office; more files can be permanently stored. Adding more memory to a system is like getting a bigger desk; you can work on more programs and data at the same time.

One difference between this analogy and the way things really work in a computer is that when a file is loaded into memory, it is a copy of the file that is actually loaded; the original still resides on the hard disk. Note that because of the temporary nature of memory, any files that have been changed after being loaded into memory must then be saved back to the hard disk before the system is powered off and the memory subsequently cleared. If the changed file is not saved, the original copy of the file on the hard disk remains unaltered. This is like saying that any changes made to files left on the desktop are discarded when the office is closed, although the original files themselves are still in the cabinet.

Memory temporarily stores programs when they are running, along with the data being used by those programs. RAM chips are sometimes termed *volatile storage* because when you turn off your computer or an electrical outage occurs, whatever is stored in RAM is lost unless you saved it to your hard drive. Because of the volatile nature of RAM, many computer users make it a habit to save their work frequently. (Some software applications can do timed backups automatically.)

Launching a computer program brings files into RAM, and as long as they are running, computer programs reside in RAM. The CPU executes programmed instructions in RAM and also stores results in RAM. RAM stores your keystrokes when you use a word processor and also stores numbers used in calculations. Telling a program to save your data instructs the program to store RAM contents on your hard drive as a file.

Physically, the *main memory* in a system is a collection of chips or modules containing chips that are usually plugged into the motherboard. These chips or modules vary in their electrical and physical designs and must be compatible with the system into which they are being installed to function properly. In this chapter, I discuss the various types of chips and modules that can be installed in different systems.

Next to the processor, memory can be one of the more expensive components in a modern PC, although the total amount spent on memory for a typical system has declined over the past few years. Even after the price drops, you should still be spending more on the memory for your system than for your motherboard—in fact, up to twice as much. Before the memory price crash in mid-1996, memory had maintained a fairly consistent price for many years of about $40 per megabyte. A typical configuration back then of 16MB cost more than $600. In fact, memory was so expensive at that time that it was worth more than its weight in gold. These high prices caught the attention of criminals as memory module manufacturers were robbed at gunpoint in several large heists. These robberies were partially induced by the fact that memory was so valuable, the demand was high, and stolen chips or modules were virtually impossible to trace. After the rash of armed robberies and other thefts, memory module manufacturers began posting armed guards and implementing beefed-up security procedures.

By the end of 1996, memory prices had cooled considerably to about $4 per megabyte—a tenfold price drop in less than a year. Prices continued to fall after the major crash until they were at or below 50 cents per megabyte in 1997. All seemed well, until events in 1998 conspired to create a spike in memory prices, increasing them by four times their previous levels. The main culprits were Intel and Rambus, who had driven the industry to support a then-new type of memory called rambus DRAM (RDRAM) and then failed to deliver the supporting components on time. The industry was caught by shifting production to a memory type that nobody could use yet, and this created a shortage of the popular SDRAM memory. An earthquake in Taiwan that year served as the icing on the cake, furthering the spike in prices.

Since then, things have cooled somewhat, and even though prices haven't dropped to their lowest levels ever, they have come down to well below a dollar per megabyte.

Memory costs less now than a few years ago, but its useful life has become much shorter. New types of memory are being adopted more quickly than before, and any new systems you purchase now most likely will not accept the same memory as your existing ones. In an upgrade or a repair situation, that means you often have to change the memory if you change the motherboard. The chance that you can reuse the memory in an existing motherboard when upgrading to a new one is slim.

Because of this, you should understand all the various types of memory on the market today, so you can best determine which types are required by which systems, and thus more easily plan for future upgrades and repairs.

To better understand physical memory in a system, you should see where and how it fits into the system. Three main types of physical memory are used in modern PCs:

- *ROM*. Read-only memory
- *DRAM*. Dynamic random access memory
- *SRAM*. Static RAM

ROM

Read-only memory, or ROM, is a type of memory that can permanently or semipermanently hold data. It is called read-only because it is either impossible or difficult to write to. ROM also is often referred to as *nonvolatile memory* because any data stored in ROM remains there, even if the power is turned off. As such, ROM is an ideal place to put the PC's startup instructions—that is, the software that boots the system.

Note that ROM and RAM are not opposites, as some people seem to believe. Both are simply types of memory. In fact, ROM could be classified as technically a subset of the system's RAM. In other words, a portion of the system's random access memory address space is mapped into one or more ROM chips. This is necessary to contain the software that enables the PC to boot up; otherwise, the processor would have no program in memory to execute when it was powered on.

◀◀ For more information on ROM, see "Motherboard BIOS," p. 349.

The main ROM BIOS is contained in a ROM chip on the motherboard, but there are also adapter cards with ROMs on them as well. ROMs on adapter cards contain auxiliary BIOS routines and drivers needed by the particular card, especially for those cards that must be active early in the boot process, such as video cards. Cards that don't need drivers active at boot time typically don't have a ROM because those drivers can be loaded from the hard disk later in the boot process.

Most systems today use a type of ROM called electrically erasable programmable ROM (EEPROM), which is a form of Flash memory. Flash is a truly nonvolatile memory that is rewritable, enabling users to easily update the ROM or firmware in their motherboards or any other components (video cards, SCSI cards, peripherals, and so on).

DRAM

Dynamic RAM (DRAM) is the type of memory chip used for most of the main memory in a modern PC. The main advantages of DRAM are that it is very dense, meaning you can pack a lot of bits into a very small chip, and it is inexpensive, which makes purchasing large amounts of memory affordable.

The memory cells in a DRAM chip are tiny capacitors that retain a charge to indicate a bit. The problem with DRAM is that it is dynamic. Also, because of the design, it must be constantly refreshed; otherwise, the electrical charges in the individual memory capacitors will drain and the data will be lost. Refresh occurs when the system memory controller takes a tiny break and accesses all the rows of data in the memory chips. Most systems have a memory controller (normally built into the North Bridge portion of the motherboard chipset), which is set for an industry-standard refresh rate of 15µs (microseconds). This means that every 15µsec, all the rows in the memory are read to refresh the data.

◀◀ See "Chipsets," p. 225.

Refreshing the memory unfortunately takes processor time away from other tasks because each refresh cycle takes several CPU cycles to complete. In older systems, the refresh cycling could take up to 10% or more of the total CPU time, but with modern systems running in the hundreds of megahertz, refresh overhead is now on the order of a fraction of a percent or less of the total CPU time. Some systems allow you to alter the refresh timing parameters via the CMOS Setup, but be aware that increasing the time between refresh cycles to speed up your system can allow some of the memory cells to begin draining, which can cause random soft memory errors to appear. A *soft error* is a data error errors to appear. A soft error that is not caused by a defective chip. It is usually safer to stick with the recommended or default refresh timing. Because refresh consumes less than 1% of modern system overall bandwidth, altering the refresh rate has little effect on performance.

DRAMs use only one transistor and capacitor pair per bit, which makes them very dense, offering more memory capacity per chip than other types of memory. Currently, DRAM chips are available with densities of up to 256Mbits or more. This means that DRAM chips are available with 256 million or more transistors! Compare this to a Pentium 4, which has 42 million transistors, and it makes the processor look wimpy by comparison. The difference is that in a memory chip, the transistors and capacitors are all consistently arranged in a (normally square) grid of simple repetitive structures, unlike the processor, which is a much more complex circuit of different structures and elements interconnected in a highly irregular fashion. At least one manufacturer is working on chips, intended for the 2001–2002 timeframe, with 256-gigabit densities using circuit line widths of 0.05 micron, indicating that memory densities will continue to rise as they have for years.

The transistor for each DRAM bit cell reads the charge state of the adjacent capacitor. If the capacitor is charged, the cell is read to contain a 1; no charge indicates a 0. The charge in the tiny capacitors is constantly draining, which is why the memory must be refreshed constantly. Even a momentary power interruption, or anything that interferes with the refresh cycles, can cause a DRAM memory cell to lose the charge and therefore the data.

DRAM is used in PC systems because it is inexpensive and the chips can be densely packed, so a lot of memory capacity can fit in a small space. Unfortunately, DRAM is also slow, normally much slower than the processor. For this reason, many types of DRAM architectures have been developed to improve performance.

Cache Memory: SRAM

Another distinctly different type of memory exists that is significantly faster than most types of DRAM. SRAM stands for Static RAM, which is so named because it does not need the periodic refresh rates like DRAM. Because of SRAM's design, not only are refresh rates unnecessary, but SRAM is much faster than DRAM and fully capable of keeping pace with modern processors.

SRAM memory is available in access times of 2ns or less, so it can keep pace with processors running 500MHz or faster! This is because of the SRAM design, which calls for a cluster of six transistors for each bit of storage. The use of transistors but no capacitors means that refresh rates are not necessary because there are no capacitors to lose their charges over time. As long as there is power, SRAM remembers what is stored. With these attributes, why don't we use SRAM for all system memory? The answers are simple:

Type	Speed	Density	Cost
DRAM	Slow	High	Low
SRAM	Fast	Low	High

Compared to DRAM, SRAM is much faster but also much lower in density and much more expensive. The lower density means that SRAM chips are physically larger and store many fewer bits overall. The high number of transistors and the clustered design mean that SRAM chips are both physically larger and much more expensive to produce than DRAM chips. For example, a DRAM module might contain 64MB of RAM or more, whereas SRAM modules of the same approximate physical size would have room for only 2MB or so of data and would cost the same as the 64MB DRAM module. Basically, SRAM is up to 30 times larger physically and up to 30 times more expensive than DRAM. The high cost and physical constraints have prevented SRAM from being used as the main memory for PC systems.

Even though SRAM is too expensive for PC use as main memory, PC designers have found a way to use SRAM to dramatically improve PC performance. Rather than spend the money for all RAM to be SRAM memory, which can run fast enough to match the CPU, designing in a small amount of high-speed SRAM memory, called cache memory, is much more cost-effective. The cache runs at speeds close to or even equal to the processor and is the memory from which the processor usually directly reads from and writes to. During read operations, the data in the high-speed cache memory is resupplied from the lower-speed main memory or DRAM in advance. Up until recently, DRAM was limited to about 60ns (16MHz) in speed. To convert access time in nanoseconds to MHz, use the following formula:

$1 / \text{nanoseconds} \times 1000 = \text{MHz}$

Likewise, to convert from MHz to nanoseconds, use the following inverse formula:

$1 / \text{MHz} \times 1000 = \text{nanoseconds}$

When PC systems were running 16MHz and less, the DRAM could fully keep pace with the motherboard and system processor, and there was no need for cache. However, as soon as processors crossed the 16MHz barrier, DRAM could no longer keep pace, and that is exactly when SRAM began to enter PC system designs. This occurred back in 1986 and 1987 with the debut of systems with the 386 processor running at 16MHz and 20MHz. These were among the first PC systems to employ what's called *cache memory*, a high-speed buffer made up of SRAM that directly feeds the processor. Because the cache can run at the speed of the processor, the system is designed so that the cache controller anticipates the processor's memory needs and preloads the high-speed cache memory with that data. Then, as the processor calls for a memory address, the data can be retrieved from the high-speed cache rather than the much lower-speed main memory.

Cache effectiveness is expressed as a hit ratio. This is the ratio of cache hits to total memory accesses. A *hit* occurs when the data the processor needs has been preloaded into the cache from the main memory, meaning that the processor can read it from the cache. A *cache miss* is when the cache controller did not anticipate the the cache. A cache miss is when the cache controller did not anticipate theneed for a specific address; the desired data was not preloaded into the cache. Therefore, the processor must retrieve the data from the slower main memory, instead of the faster cache. Anytime the processor reads data from main memory, the processor must wait because the main memory cycles at a much slower rate than the processor. If the processor is running at 1000MHz, it is cycling at 1ns, whereas the main memory might be 7.5ns, which means it is running at only 133MHz. Therefore, every time the processor reads from main memory, it would effectively slow down to 133MHz! The slowdown is accomplished by having the processor execute what are called *wait states*, which are cycles in which nothing is done; the processor essentially cools its heels while waiting for the slower main memory to return the desired data. Obviously, you don't want your processors slowing down, so cache function and design become important as system speeds increase.

To minimize the processor being forced to read data from the slow main memory, two stages of cache usually exist in a modern system, called Level 1 (L1) and Level 2 (L2). The L1 cache is also called *integral* or *internal cache* because it is directly built into the processor and is actually a part of the processor die (raw chip). Because of this, L1 cache always runs at the full speed of the processor core and is the fastest cache in any system. All 486 and higher processors incorporate integral L1 cache, making them significantly faster than their predecessors. L2 cache is also called *external cache* because it is external to the processor chip. Originally, this meant it was installed on the motherboard, as was the case with all 386, 486, and Pentium systems. In those systems, the L2 cache runs at motherboard speed because it is installed on the motherboard. You typically can find the L2 cache directly next to the processor socket in Pentium and earlier systems.

◀◀ See "How Cache Works," p. 62.

In the interest of improved performance, later processor designs from Intel and AMD have included the L2 cache as a part of the processor. In all the processors since late 1999 (and some earlier models), the L2 cache was directly incorporated as a part of the processor die just like the L1 cache. In chips with on-die L2, the cache runs at the full core speed of the processor and is much more efficient. By contrast, most processors from 1999 and earlier had L2 cache in separate chips that were external to the main processor core. The L2 cache in many of these older chips ran at only half or one-third the processor core speed. Prior to the inclusion of L2 cache in the processor, the L2 was on the motherboard, where it ran even more slowly. Cache speed is very important, so systems having L2 cache on the motherboard were the slowest. Including L2 inside the processor made it faster, and including it directly on the processor die (rather than as chips external to the die) is the fastest yet. Any chip that has on-die full core speed L2 cache has a distinct performance advantage over any chip that doesn't.

Processors with built-in L2 cache, whether it's on-die or not, still run the cache more quickly than any fo*und on the motherboard. Thus, most motherboards designed for processors with built-in cache don't have any cache on the board; all the cache is contained in the processor module instead.

The new Itanium processor from Intel has three levels of cache within the processor module for even greater performance. More cache and more levels of cache help mitigate the speed differential between the fast processor core and the relatively slow motherboard and main memory.

The key to understanding both cache and main memory is to see where they fit in the overall system architecture.

Figure 6.1 shows the system architecture for a typical Pentium system with an Intel chipset.

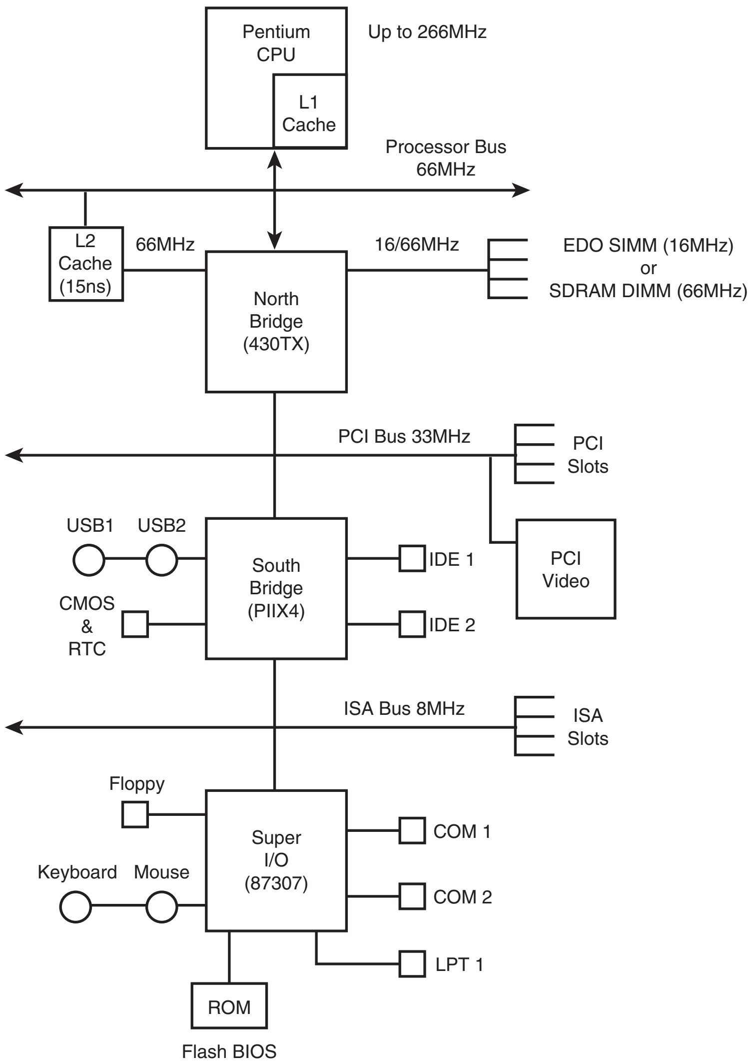


Figure 6.1 System architecture: Pentium system with an Intel chipset.

See Chapter 4, "Motherboards and Buses," for a diagram showing a typical Pentium III system with integrated L2 cache.

Table 6.1 illustrates the need for and function of L1 (internal) and L2 (external) cache in modern systems.

Cache designs were originallyCache designs originally were *asynchronous*, meaning they ran at a clock speed that was not identical or in sync with the processor bus. Starting with the 430FX chipset released in early 1995, a new type of synchronous cache design was supported. It required that the chips now run in sync or at the same identical clock timing as the processor bus, further improving speed and performance. Also added at that time was a feature called *pipeline burst mode*, which reduces overall cache latency (wait states) by allowing single-cycle accesses for multiple transfers after the first one. Because both synchronous and pipeline burst capability came at the same time in new modules, specifying one usually implies the other. Synchronous pipeline burst cache allowed for about a 20% improvement in overall system performance, which was a significant jump.

The cache controller for a modern system is contained in either the North Bridge of the chipset, as with Pentium and lesser systems, or within the processor, as with the Pentium Pro/II and newer systems. The capabilities of the cache controller dictate the cache's performance and capabilities. One important thing to note is that most cache controllers have a limitation on the amount of memory that can be cached. Often, this limit can be quite low, as with the 430TX chipset-based Pentium systems. The 430TX chipset can cache data only within the first 64MB of system RAM. If you have more memory than that, you will see a noticeable slowdown in system performance because all data outside the first 64MB is never cached and is always accessed with all the wait states required by the slower DRAM. Depending on what software you use and where data is stored in memory, this can be significant. For example, 32-bit operating systems, such as Windows 9x and NT, load from the top down, so if you had 96MB of RAM, the operating system and applications would load directly into the upper 32MB (past 64MB), which is not cached. This results in a dramatic slowdown in overall system use. Removing the additional memory to bring the system total down to the cacheable limit of 64MB is the solution. In short, it is unwise to install more main RAM memory than your system (chipset) can cache. Consult your system documentation or the chipset section in Chapter 4 for more information.

Table 6.1 The Relationship Between L1 (Internal) and L2 (External) Cache in Modern Systems

CPU Type	486 DX4	Pentium	Pentium Pro	Pentium II	Pentium II	AMD K6-2	AMD K6-3
CPU speed	100MHz	233MHz	200MHz	333MHz	450MHz	550MHz	450MHz
L1 cache speed	10ns (100MHz)	4.3ns (233MHz)	5.0ns (200MHz)	3.0ns (333MHz)	2.2ns (450MHz)	1.8ns (550MHz)	2.2ns (450MHz)
L1 cache size	16K	16K	32K	32K	32K	64K	64K
L2 cache location	Motherboard	Motherboard	Chip	Chip	Chip	Motherboard	On-die
L2 core/ cache ratio	-	-	1/1	1/2	1/2	-	1/1
L2 cache speed	30ns (33MHz)	15ns (66MHz)	5ns (200MHz)	6ns (166MHz)	4.4ns (225MHz)	10ns (100MHz)	2.2ns (450MHz)
L2 cache size	varies[1]	varies[1]	256K[2]	512K	512K	varies[1]	256K
Motherboard speed	33MHz	66MHz	66MHz	66MHz	100MHz	100MHz	100MHz
SIMM/DIMM speed	60ns (16MHz)	60ns (16MHz)	60ns (16MHz)	15ns (66MHz)	10ns (100MHz)	10ns (100MHz)	10ns (100MHz)

1. The L2 cache is on the motherboard, and the amount depends on which board is chosen and how much is installed.

2. The Pentium Pro also was available with 512KB and 1024KB L2 cache.

3. The Athlon uses a 200MHz bus between the CPU and North Bridge; however, the board and main memory still run at 100MHz.

RAM Memory Types

The speed and performance issue with memory is confusing to some because memory speed is usually expressed in ns (nanoseconds), and processor speed has always been expressed in MHz (megahertz). Recently, however, some newer and faster types of memory have speeds expressed in MHz, adding to the confusion. Let's see if we can come up with a way to translate one to the other.

A *nanosecond* is defined as one billionth of a second—a very short time indeed. To put some perspective on that, the speed of light is 186,282 miles (299,792 kilometers) per second in a vacuum. In one billionth of a second, a beam of light travels a mere 11.80 inches or 29.98 centimeters—less than the length of a typical ruler!

Chip and system speed has been expressed in megahertz (MHz), which is millions of cycles per second. Some systems today have processors running up to and beyond 2000MHz (2GHz or two billion cycles per second), and we should see processors approaching 3GHz or 4GHz by next year.

Because it is confusing to speak in these different terms for speeds, I thought it would be interesting to see how they compare. Table 6.2 shows the relationship between nanoseconds (ns) and megahertz (MHz) for the speeds associated with PCs from yesterday to today and tomorrow.

	Pentium III	AMD Athlon	AMD Athlon	AMD Duron	AMD Athlon (Thunderbird)	Celeron	Pentium III (Coppermine)	Pentium 4
	600MHz	800MHz	1,000MHz	800MHz	1,000MHz	800MHz	1,000MHz	1.7GHz
	1.6ns (600MHz)	1.3ns (800MHz)	1ns (1,000MHz)	1.3ns (800MHz)	1ns (1,000MHz)	1.3ns (800MHz)	1ns (1,000MHz)	0.6ns (1.7GHz)
	32K	128K	128K	128K	128K	32K	32K	20K
	Chip	Chip	Chip	on-die	On-die	On-die	On-die	On-die
	1/2	2/5	1/3	1/1	1/1	1/1	1/1	1/1
	3.3ns (300MHz)	3.1ns (320MHz)	3ns (333MHz)	1.3ns (800MHz)	1ns (1,000MHz)	1.3ns (800MHz)	1ns (1,000MHz)	0.6ns (1.7GHz)
	512K	512K	512K	64K	256K	128K	256K	256K
	100MHz	100MHz[3]	100MHz[3]	100MHz[3]	266MHz	100MHz	133MHz	400MHz
	10ns (100MHz)	10ns (100MHz)	10ns (100MHz)	10ns (100MHz)	3.8ns (266MHz)	10ns (100MHz)	7.5ns (133MHz)4	2.5ns (400MHz)

4. These systems also can support PC800 RDRAM RIMM memory, which has about twice the bandwidth of PC100 and 1.5 times that of PC133.

5. Katmai is the codename for the first-generation Pentium III.

6. Coppermine is the codename for the second-generation Pentium III (0.18 micron, on-die L2 cache).

7. Thunderbird is the codename for the third-generation (Model 4) Athlon (0.18 micron, on-die L2 cache).

Table 6.2 The Relationship Between Megahertz (MHz) and Cycle Times in Nanoseconds (ns)

Clock Speed	Cycle Time	Clock Speed	Cycle Time	Clock Speed	Cycle Time
4.77MHz	210ns	225MHz	4.4ns	750MHz	1.33ns
6MHz	167ns	233MHz	4.3ns	766MHz	1.31ns

16MHz	63ns	333MHz	3.0ns	866MHz	1.15ns
20MHz	50ns	350MHz	2.9ns	900MHz	1.11ns
25MHz	40ns	366MHz	2.7ns	933MHz	1.07ns
33MHz	30ns	400MHz	2.5ns	950MHz	1.05ns
40MHz	25ns	433MHz	2.3ns	966MHz	1.04ns
50MHz	20ns	450MHz	2.2ns	1,000MHz	1.00ns

Table 6.2 Continued

Clock Speed	Cycle Time	Clock Speed	Cycle Time	Clock Speed	Cycle Time
60MHz	17ns	466MHz	2.1ns	1,100MHz	0.91ns
66MHz	15ns	500MHz	2.0ns	1,133MHz	0.88ns
75MHz	13ns	533MHz	1.88ns	1,200MHz	0.83ns
80MHz	13ns	550MHz	1.82ns	1,300MHz	0.77ns
100MHz	10ns	566MHz	1.77ns	1,400MHz	0.71ns
120MHz	8.3ns	600MHz	1.67ns	1,500MHz	0.67ns
133MHz	7.5ns	633MHz	1.58ns	1,600MHz	0.63ns
150MHz	6.7ns	650MHz	1.54ns	1,700MHz	0.59ns
166MHz	6.0ns	666MHz	1.50ns	1,800MHz	0.56ns
180MHz	5.6ns	700MHz	1.43ns	1,900MHz	0.53ns
200MHz	5.0ns	733MHz	1.36ns	2,000MHz	0.50ns

As you can see from this table, as clock speeds increase, cycle time decreases proportionately.

If you examine Table 6.2, you can clearly see that the 60ns DRAM memory used in the typical PC for many years is totally inadequate when compared to processor speeds of 400MHz and higher. Up until 1998, most DRAM memory used in PCs had been rated at an access time of 60ns or higher, which works out to be 16.7MHz or slower! This super-slow 16MHz memory had been installed in systems running up to 300MHz or faster, and you can see what a mismatch has existed between processor and main memory performance. The dominant standard in 2000 was to have 100MHz and even 133MHz memory, called PC100 and PC133, respectively. Starting in early 2001, double data rate (DDR) memory of 200MHz and 266MHz become popular, along with 800MHz RDRAM.

System memory timing is a little more involved than simply converting nanoseconds to megahertz. The transistors for each bit in a memory chip are most efficiently arranged in a grid, using a row and column scheme to access each transistor. All memory accesses involve selecting a row address and then a column address, and then transferring the data. The initial setup for a memory transfer where the row and column addresses are selected is a necessary overhead normally referred to as *latency*. The access time for memory is the cycle time plus latency for selecting the row and column addresses. For example, SDRAM memory rated at 133MHz (7.5ns) typically takes five cycles to set up and complete the first transfer ($5 \times 7.5\text{ns} = 37.5\text{ns}$) and then perform three additional transfers with no additional setup. Thus, four transfers take a total eight cycles, or an average of about two cycles per transfer.

What happens when a 1GHz processor is trying to read multiple bytes of data from 133MHz memory? A lot of wait states! A wait state is an additional “do nothing” cycle that the processor must execute while waiting for the data to become ready. With memory cycling every 7.5ns (133MHz) and a processor cycling every 1ns (1GHz), the processor must execute approximately six wait states before the data is ready on the seventh cycle. Adding wait states in this fashion effectively slows the processing speed to that of the memory, or 133MHz in this example. To reduce the number of wait states required, several types of faster memory and cache are available, all of which are discussed in this chapter.

Over the development life of the PC, memory has had a difficult time keeping up with the processor, requiring several levels of high-speed cache memory to intercept processor requests for the slower main memory. Table 6.3 shows the progress and relationship between system board (motherboard) speeds in PCs and the various types and speeds of main memory or RAM used and how these changes have affected total bandwidth.

Table 6.3 Memory Bus Bandwidth

Memory Bus Type	Memory Bus Width (bytes)	Memory Bus Speed (MHz)	Data Cycles per Clock	Bandwidth (MB/sec)
FPM DRAM	8	22	1	177
EDO DRAM	8	33	1	266
PC66 SDRAM	8	66	1	533
PC100 SDRAM	8	100	1	800
PC133 SDRAM	8	133	1	1,066
PC1600 DDR-SDRAM	8	100	2	1,600
PC2100 DDR-SDRAM	8	133	2	2,133
PC600 RDRAM	2	300	2	1,200
PC700 RDRAM	2	350	2	1,400
PC800 RDRAM	2	400	2	1,600
PC800 RDRAM Dual Channel	4	400	2	3,200

Generally, things work best when the throughput of the memory bus matches the throughput of the processor bus. Compare the memory bus speeds to the speeds of the processor bus (in Table 6.4), and you'll see that some of the memory bus speeds match that of some of the processor bus speeds. In most cases the type of memory that matches the CPU bus throughput is the best type of memory for systems with that type of processor.

Table 6.4 shows the relative speeds of the various processor buses according to bandwidth.

Table 6.4 Processor Bus Bandwidth

CPU Bus Type	CPU Bus Width (bytes)	CPU Bus Speed (MHz)	Data Cycles per Clock	Bandwidth (MB/sec)
33MHz 486 CPU FSB	32	33	1	133
66MHz 64-bit CPU FSB	64	66	1	533
100MHz 64-bit CPU FSB	64	100	1	800
133MHz 64-bit CPU FSB	64	133	1	1,066
200MHz 64-bit CPU FSB	64	100	2	1,600
266MHz 64-bit CPU FSB	64	133	2	2,133
400MHz 64-bit CPU FSB	64	100	4	3,200

FSB = Front Side Bus

Because the processor is fairly well insulated from directly dealing with main memory by the L1 and L2 cache, memory performance has often lagged behind the performance of the processor bus. More recently, however, systems using SDRAM, DDR SDRAM, and RDRAM have memory bus performance equaling that of the processor bus. When the speed of the memory bus equals the speed of the processor bus, memory performance is optimum for that system.

Fast Page Mode DRAM

Standard DRAM is accessed through a technique called *paging*. Normal memory access requires that a row and column address be selected, which takes time. Paging enables faster access to all the data within a given row of memory by keeping the row address the same and changing only the column.

Memory that uses this technique is called *Page Mode* or *Fast Page Mode* memory. Other variations on Page Mode were called *Static Column* or *Nibble Mode* memory.

Paged memory is a simple scheme for improving memory performance that divides memory into pages ranging from 512 bytes to a few kilobytes long. The paging circuitry then enables memory locations in a page to be accessed with fewer wait states. If the desired memory location is outside the current page, one or more wait states are added while the system selects the new page.

To improve further on memory access speeds, systems have evolved to enable faster access to DRAM. One important change was the implementation of burst mode access in the 486 and later processors. Burst mode cycling takes advantage of the consecutive nature of most memory accesses. After setting up the row and column addresses for a given access, using burst mode, you can then access the next three adjacent addresses with no additional latency or wait states. A burst access usually is limited to four total accesses. To describe this, we often refer to the timing in the number of cycles for each access. A typical burst mode access of standard DRAM is expressed as x-y-y-y; *x* is the time for the first access (latency plus cycle time), and *y* represents the number of cycles required for each consecutive access.

Standard 60ns DRAM normally runs 5-3-3-3 burst mode timing. This means the first access takes a total of five cycles (on a 66MHz system bus, this is about 75ns total or 5×15ns cycles), and the consecutive cycles take three cycles each (3×15ns = 45ns). As you can see, the actual system timing is somewhat less than the memory is technically rated for. Without the bursting technique, memory access would be 5-5-5-5 because the full latency is necessary for each memory transfer.

DRAM memory that supports paging and this bursting technique is called *Fast Page Mode (FPM)* memory. The term comes from the capability of memory accesses to data on the same page to be done with less latency. Most 486 and Pentium systems from 1995 and earlier use FPM memory.

Another technique for speeding up FPM memory was a technique called *interleaving*. In this design, two separate banks of memory are used together, alternating access from one to the other as even and odd bytes. While one is being accessed, the other is being precharged, when the row and column addresses are being selected. Then, by the time the first bank in the pair is finished returning data, the second bank in the pair is finished with the latency part of the cycle and is now ready to return data. While the second bank is returning data, the first bank is being precharged, selecting the row and column address of the next access. This overlapping of accesses in two banks reduces the effect of the latency or precharge cycles and allows for faster overall data retrieval. The only problem is that to use interleaving, you must install identical pairs of banks together, doubling the amount of SIMMs or DIMMs required. This method was popular on 32-bit wide memory systems on 486 processors but fell out of favor on Pentiums because of their 64-bit wide memory widths. To perform interleaving on a Pentium machine, you would need to install memory 128 bits at a time, meaning four 72-pin SIMMs or two DIMMs at a time.

Extended Data Out RAM

In 1995, aA newer type of memory called extended data out (EDO) RAM became available for Pentium systems. EDO, a modified form of FPM memory, is sometimes referred to as *Hyper Page mode*. EDO was invented and patented by Micron Technology, although Micron licensed production to many other memory manufacturers. EDO memory consists of specially manufactured chips that allow a timing overlap between successive accesses. The name *extended data out* refers specifically to the fact that unlike FPM, the data output drivers on the chip are not turned off when the memory controller removes the column address to begin the next cycle. This enables the next cycle to overlap the previous one, saving approximately 10ns per cycle.

The effect of EDO is that cycle times are improved by enabling the memory controller to begin a new column address instruction while it is reading data at the current address. This is almost identical to what was achieved in older systems by interleaving banks of memory, but unlike interleaving, with EDO you didn't need to install two identical banks of memory in the system at a time.

EDO RAM allows for burst mode cycling of 5-2-2-2, compared to the 5-3-3-3 of standard fast page mode memory. To do four memory transfers, then, EDO would require 11 total system cycles, compared to 14 total cycles for FPM. This is a 22% improvement in overall cycling time, but in actual testing, EDO typically increases overall system benchmark speed by about 5%. Even though the overall system improvement might seem small, the important thing about EDO was that it used the same basic DRAM chip design as FPM, meaning that there was practically no additional cost over FPM. In fact, in its heyday, EDO cost less than FPM and yet offered higher performance.

EDO RAM generally comes in 72-pin SIMM form. Figure 6.4 (later in this chapter) shows the physical characteristics of these SIMMs.

To actually use EDO memory, your motherboard chipset must support it. Most motherboard chipsets—starting in 1995 with the Intel 430FX (Triton) and through 1997—offered support for EDO. Because EDO memory chips cost the same to manufacture as standard chips, combined with Intel's support of EDO in all its chipsets, the PC market jumped on the EDO bandwagon full force.

◂◂ See "Fifth-Generation (P5 Pentium Class) Chipsets," p. 234, and "Sixth-Generation (P6 Pentium Pro/Pentium II/III Class) Chipsets," p. 246.

EDO RAM is ideal for systems with bus speeds of up to 66MHz, which fit perfectly with the PC market up through 1997. However, since 1998, the market for EDO has rapidly declined as the newer and faster SDRAM architecture has become the standard for new PC system memory.

Burst EDO

A variation of EDO is burst extended data out dynamic random access memory (BEDO DRAM). *BEDO* is basically EDO memory with special burst features for even speedier data transfers than standard EDO. Unfortunately, only one chipset (Intel 440FX Natoma) ever supported it, and it was quickly overshadowed by SDRAM, which seemed to be favored among PC system chipset and system designers. As such, BEDO never really saw the light of production, and to my knowledge no systems ever really used it.

SDRAM

Synchronous DRAM (SDRAM) is for Synchronous DRAM, a type of DRAM that runs in synchronization with the memory bus. SDRAM delivers information in very high-speed bursts using a high-speed, clocked interface. SDRAM removes most of the latency involved in asynchronous DRAM because the signals are already in synchronization with the motherboard clock.

Like EDO RAM, your chipset must support this type of memory for it to be usable in your system. Starting in 1997 with the 430VX and 430TX, most of Intel's chipsets began to support SDRAM, making it the most popular type of memory for new systems through 2000 and even into 2001.

SDRAM's performance is dramatically improved over FPM or EDO RAM. Because SDRAM is still a type of DRAM, the initial latency is the same, but overall cycle times are much faster than with FPM or EDO. SDRAM timing for a burst access would be 5-1-1-1, meaning that four memory reads would complete in only eight system bus cycles, compared to eleven cycles for EDO and fourteen cycles for FPM. This makes SDRAM almost 20% faster than EDO.

Besides being capable of working in fewer cycles, SDRAM is also capable of supporting up to 133MHz (7.5ns) system bus cycling. As such, most new PC systems sold in 1998, and through 2000, have included SDRAM memory.

SDRAM is sold in DIMM form and often is rated by megahertz speed rather than nanosecond cycling time, which can be kind of confusing. Figure 6.5 (later in this chapter) shows the physical characteristics of DIMMs.

To meet the stringent timing demands of its chipsets, Intel created specifications for SDRAM called PC66, PC100, and PC133. To meet the PC100 specification, 8ns chips usually are required. Normally, you would think 10ns would be considered the proper rating for 100MHz operation, but the PC100 specification calls for faster memory to ensure all timing parameters are met.

In May of 1999, the Joint Electron Device Engineering Council (JEDEC), an organization that creates most of the memory specifications used in the industry, created the PC133. They achieved this 33MHz speed increase by taking the PC100 specification and tightening up the timing and capacitance parameters. The faster PC133 quickly caught on as the most popular version of SDRAM for any systems running a 133MHz processor bus.

Table 6.5 shows the timing, actual speed, and rated speed for various SDRAM DIMMs.

Table 6.5 SDRAM Timing, Actual Speed, and Rated Speed

Timing	Actual Speed	Rated Speed
15ns	66MHz	PC66
10ns	100MHz	PC66
8ns	125MHz	PC100
7.5ns	133MHz	PC133

▶▶ See "SIMMs, DIMMs, and RIMMs," p. 421.

DDR SDRAM

Double data rate (DDR) SDRAM memory is an evolutionary design of standard SDRAM in which data is transferred twice as quickly. Instead of doubling the actual clock rate, DDR memory achieves the doubling in performance by transferring twice per transfer cycle: once at the leading (falling) edge and once at the trailing (rising) edge of the cycle (see Figure 6.2). This is similar to the way RDRAM operates and effectively doubles the transfer rate, even though the same overall clock and timing signals are used.

DDR, which found most of its initial support in the graphics card market, is also supported in many of the newest motherboard chipsets, including those for server use. It seems the server market is more comfortable with DDR SDRAM—which is almost identical to previous SDRAM, except for the double clocking—than it is with the more radical RDRAM. As such, DDR SDRAM is supported by processor companies, including Intel, AMD, and Cyrix, and chipset manufacturers, including Intel, VIA Technologies, ALi (Acer Labs, Inc.), and SiS (Silicon Integrated Systems). The DDR Consortium, an industry panel consisting of Fujitsu, Ltd.; Hitachi, Ltd.; Hyundai Electronics Industries Co.; Mitsubishi Electric Corp.; NEC Corp.; Samsung Electronics Co.; Texas Instruments, Inc.; and Toshiba Corp. undertook official standardization of DDR.

DDR SDRAM came to market during 2000, but it didn't really catch on until the advent of mainstream motherboards and chipsets supporting it during 2001.

DDR SDRAM uses a new DIMM module design with 184 pins. Figure 6.6 (later in this chapter) shows the DDR SDRAM DIMM.

DDR DIMMs are rated for either PC1600 (200MHz × 8) or PC2100 (266MHz × 8) operation and normally run on 2.5 volts. They are basically an extension of the PC100 and PC133 DIMMs redesigned to support double clocking, where data is sent on each clock transition (twice per cycle) rather than once per cycle as with standard SDRAM.

RDRAM

Rambus DRAM (RDRAM) is a fairly radical memory design found in high-end PC systems starting in late 1999. Intel signed a contract with Rambus in 1996 ensuring they would support RDRAM into 2001.

Rambus developed what is essentially a chip-to-chip memory bus, with specialized devices that communicate at very high rates of speed. What might be interesting to some is that this technology was first developed for game systems and first made popular by the Nintendo 64 game system and subsequently was used in the Sony Playstation 2.

Conventional memory systems that use FPM/EDO or SDRAM are known as *wide-channel systems*. They have memory channels as wide as the processor's data bus, which for the Pentium and up is 64 bits. The dual inline memory module (DIMM) is a 64-bit wide device, meaning data can be transferred to it 64 bits (or 8 bytes) at a time.

RDRAMs, on the other hand, are narrow-channel devices. They transfer data only 16 bits (2 bytes) at a time (plus 2 optional parity bits), but at much faster speeds.

RIMMs typically run 800MHz, so the overall throughput is 800 × 2, or 1.6GB per second for a single channel—the same as PC1600 DDR SDRAM. The RDRAM design features less latency between transfers because they all run synchronously in a looped system and in only one direction. For further increases in speed, you can use two or four RDRAM channels simultaneously, increasing memory throughput to 3.2GB/sec or 6.4GB/sec if necessary. Currently, motherboards exist that use dual-channel RDRAM designs. Dual-channel PC800 RDRAM is also currently the fastest type of PC memory, followed by PC2100 DDR SDRAM. Whether your board supports (requires) dual-channel RDRAM is dictated by the motherboard chipset; currently, the Intel 840 and 850 chipsets support dual-channel RDRAM.

A single Rambus memory channel can support up to 32 individual RDRAM devices (the RDRAM chips), more if buffers are used. Each individual chip is serially connected to the next on a package called a Rambus inline memory module (RIMM), but all memory transfers are done between the memory controller and a single device, not between devices. The individual RDRAM chips are contained on RIMMs, and a single channel normally has three RIMM sockets. The RDRAM memory bus is a continuous path through each device and module on the bus, with each module having input and output pins on opposite ends. Therefore, any RIMM sockets not containing a RIMM must then be filled with a continuity module to ensure that the path is completed. The signals that reach the end of the bus are terminated on the motherboard.

Each RDRAM on a RIMM essentially operates as a standalone module sitting on the 16-bit data bus. Internally, each RDRAM chip has a core that operates on a 128-bit wide bus split into eight 16-bit banks running at 100MHz. In other words, every 10ns (100MHz), each RDRAM chip can transfer 16 bytes to and from the core. This internally wide, yet externally narrow, high-speed interface is the key to RDRAM.

Other improvements to the design include separating control and data signals on the bus. There are independent control and address buses split into two groups of pins for row and column commands, while data is transferred across the 2-byte wide data bus. The actual memory bus clock runs at

400MHz; however, data is transferred on both the falling and rising edges of the clock signal, or twice per clock pulse. The falling edge is called an *even cycle*, and the rising edge is called an *odd cycle*. Complete memory bus synchronization is achieved by sending packets of data beginning on an even cycle interval. The overall wait before a memory transfer can begin (latency) is only one cycle, or 2.5ns maximum.

Figure 6.2 shows the relationship between clock and data cycles; you can see five total clock cycles (each with a falling and a rising edge) and 10 data cycles in the same time. An RDRAM data packet always begins on an even (falling) transition for synchronization purposes.

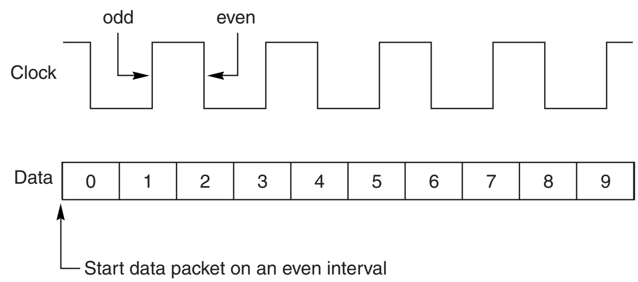

Figure 6.2 RDRAM clock and data cycle relationship.

The architecture also supports multiple, simultaneous interleaved transactions in multiple separate time domains. Therefore, before a transfer has even completed, another can begin.

Another important feature of RDRAM is that it is a low-power memory system. The RIMMs themselves as well as the RDRAM devices run on only 2.5 volts and use low-voltage signal swings from 1.0v to 1.8v, a swing of only 0.8v total. RDRAMs also have four power-down modes and can automatically transition into standby mode at the end of a transaction, which offers further power savings.

As discussed, RDRAM chips are installed in modules called RIMMs. A RIMM (shown in Figure 6.3, later in this chapter) is similar in size and physical form to current DIMMs, but they are not interchangeable. RIMMs are available in 64MB, 128MB, and 256MB capacities. They can be added to a system one at a time because each individual RIMM technically represents multiple banks to a system.

An RDRAM memory controller with a single Rambus channel supports up to three RIMM modules according to the design. However, most motherboards implement only two modules per channel to avoid problems with signal noise.

With Intel throwing its weight behind the Rambus memory, it seemed to be a sure thing for success. Unfortunately, delays in the chipsets due to technical difficulties with RDRAM memory designs have caused the RIMM modules to be priced three or more times that of a comparatively sized DIMM. Although the performance of RDRAM seems good, DDR SDRAM actually performs better in most systems and at significantly less cost. Unfortunately for the memory chip manufacturers, it seems that Rambus has claimed patents that cover both standard and DDR SDRAM designs, so regardless of whether these companies manufacture SDRAM, DDR, or RDRAM, they must pay royalties to Rambus. Several court cases are ongoing with companies challenging these patents, and a lot is riding on the outcome.

Memory Modules

The CPU and motherboard architecture (chipset) dictates a particular computer's physical memory capacity and the types and forms of memory that can be installed. Over the years, two main changes have occurred in computer memory—it has gradually become faster and wider. The CPU and the memory controller circuitry indicate the speed and width requirements. The memory controller in a modern PC resides in the motherboard chipset. Even though a system might physically support a given amount of memory, the type of software you run could dictate whether all the memory can be used.

The 8088 and 8086, with 20 address lines, can use as much as 1MB (1,024KB) of RAM. The 286 and 386SX CPUs have 24 address lines and can keep track of as much as 16MB of memory. The 386DX, 486, Pentium, Pentium-MMX, and Pentium Pro CPUs have a full set of 32 address lines, so they can keep track of 4GB of memory; the Pentium II/III and 4, as well as the AMD Athlon and Duron, have 36 address lines and can manage an impressive 64GB. The new Itanium processor, on the other hand, has 44-bit addressing, which allows for up to 16TB (terabytes) of physical RAM!

◀◀ See "Processor Specifications," p. 42.

When the 286 and higher chips emulate the 8088 chip (as they do when running 16-bit software, such as DOS or Windows 3.x), they implement a hardware operating mode called *real mode*. Real mode is the only mode available on the 8086 and 8088 chips used in PC and XT systems. In real mode, all Intel processors—even the mighty Pentium—are restricted to using only 1MB of memory, just as their 8086 and 8088 ancestors were, and the system design reserves 384KB of that amount. Only in protected mode can the 286 or better chips use their maximum potentials for memory addressing.

◀◀ See "Processor Modes," p. 67.

P5 class systems can address as much as 4GB of memory, and P6/P7 class systems can address up to 64GB. To put these memory-addressing capabilities into perspective, 64GB (65,536MB) of memory would cost about $70,000! Even if you could afford all this memory, some of the largest memory modules available today are 1GB DIMMs. To install 64GB of RAM would require 64 of the largest 1GB DIMMs available, and most systems today support up to only four DIMM sockets.

Most motherboards have a maximum of only three to six DIMM sockets, which allows a maximum of .75GB–1.5GB if all the sockets are filled. These limitations are from the chipset, not the processor. Although some processors can address 64GB, there isn't a chipset on the market that will allow that! Most of the chipsets today are limited to 1GB of memory, although some handle up to 4GB or more.

Some systems have even more limitations. P5 class systems have been available since 1993, but only those built in 1997 or later use a motherboard chipset that supports SDRAM DIMMs. Even those using the most recent P5 class chipset from Intel, such as the 430TX, do not support more than 256MB of total memory and should not have more than 64MB actually installed because of memory-caching limitations. Don't install more than 64MB of RAM in one of these systems unless you are sure the motherboard and chipset will allow the L2 cache to function with the additional memory.

Note

See the "Chipsets" section in Chapter 4 for the maximum cacheable limits on all the Intel and other motherboard chipsets.

SIMMs, DIMMs, and RIMMs

Originally, systems had memory installed via individual chips. They are often referred to as *dual inline package (DIP)* chips because of their designs. The original IBM XT and AT had 36 sockets on the motherboard for these individual chips, and then more of them were installed on the memory cards plugged into the bus slots. I remember spending hours populating boards with these chips, which was a tedious job.

Besides being a time-consuming and labor-intensive way to deal with memory, DIP chips had one notorious problem—they crept out of their sockets over time as the system went through thermal cycles. Every day, when you powered the system on and off, the system heated and cooled, and the chips gradually walked their way out of the sockets. Eventually, good contact was lost and memory errors resulted. Fortunately, reseating all the chips back in their sockets usually rectified the problem, but that method was labor intensive if you had a lot of systems to support.

The alternative to this at the time was to have the memory soldered into either the motherboard or an expansion card. This prevented the chips from creeping and made the connections more permanent, but that caused another problem. If a chip did go bad, you had to attempt desoldering the old one and resoldering a new one or resort to scrapping the motherboard or memory card on which the chip was installed. This was expensive and made memory troubleshooting difficult.

What was necessary was a chip that was both soldered and removable, and that is exactly what was found in the module called a *SIMM*. For memory storage, most modern systems have adopted the single inline memory module (SIMM), dual inline memory module (DIMM), or RIMM as an alternative to individual memory chips. These small boards plug into special connectors on a motherboard or memory card. The individual memory chips are soldered to the module, so removing and replacing them is impossible. Instead, you must replace the entire module if any part of it fails. The module is treated as though it were one large memory chip.

There are two main types of SIMMs, two main types of DIMMs, and so far one type of RIMM used in desktop systems. The various types are often described by their pin count, memory row width, or memory type.

SIMMs, for example, were available in two main physical types—30-pin (8 bits plus an option for 1 additional parity bit) and 72-pin (32 bits plus an option for 4 additional parity bits)—with various capacities and other specifications. The 30-pin SIMMs are physically smaller than the 72-pin versions, and either version can have chips on one or both sides.

DIMMs are also available in two types. DIMMs usually hold standard SDRAM or DDR SDRAM chips, and they are distinguished by different physical characteristics. Standard DIMMs have 168 pins, one notch on either side, and two notches along the contact area. DDR DIMMs, on the other hand, have 184 pins, two notches on each side, and only one notch along the contact area. All DIMMs are either 64-bits (nonparity) or 72-bits (parity or error correcting code [ECC]) wide (data paths). The main physical difference between SIMMs and DIMMs is that DIMMs have different signal pins on each side of the module. That is why they are called *dual* inline memory modules, and why with only an inch of additional length, they have many more pins than a SIMM.

RIMMs are also double-sided. Only one type of RIMM is available, which has 184 pins, one notch on either side, and two notches centrally located in the contact area. All RIMMs are either 16-bits wide or 18-bits wide (data path) for non-ECC and ECC versions, respectively.

Figures 6.3–6.7 show a typical 30-pin (8-bit) SIMM, 72-pin (32-bit) SIMM, 168-pin SDRAM DIMM, 184-pin DDR SDRAM (64-bit) DIMM, and 184-pin RIMM, respectively. The pins are numbered from left to right and are connected through to both sides of the module on the SIMMs. The pins on the DIMM are different on each side, but on a SIMM, each side is the same as the other and the connections carry through. Note that all dimensions are in both inches and millimeters (in parentheses).

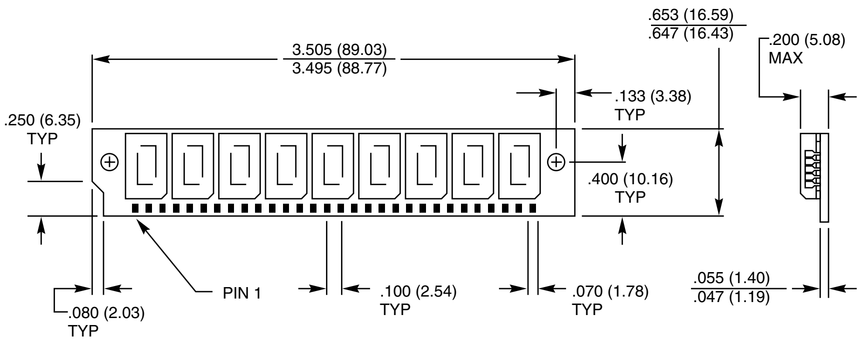

Figure 6.3 A typical 30-pin SIMM. The one shown here is 9-bit, although the dimensions would be the same for 8-bit.

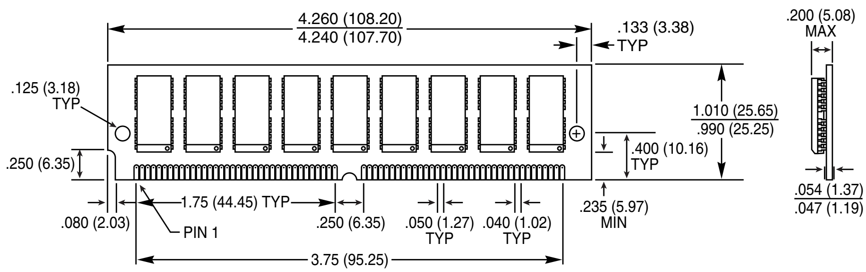

Figure 6.4 A typical 72-pin SIMM. The version shown here is 36-bit, although the dimensions would be the same for 32-bit.

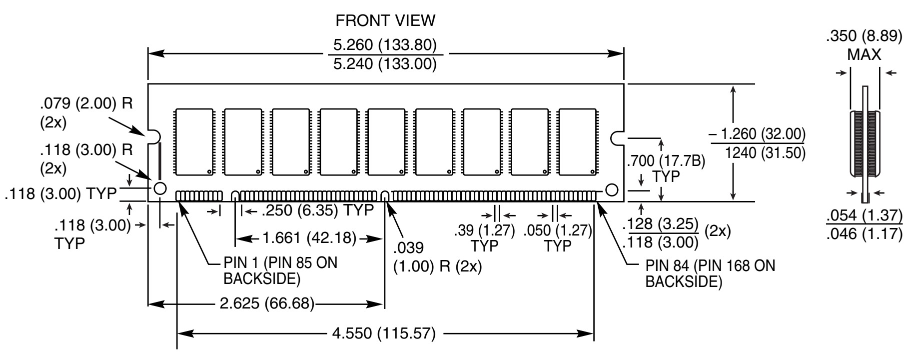

Figure 6.5 A typical 168-pin SDRAM DIMM. The one shown here is 72-bit, although the dimensions would be the same for 64-bit.

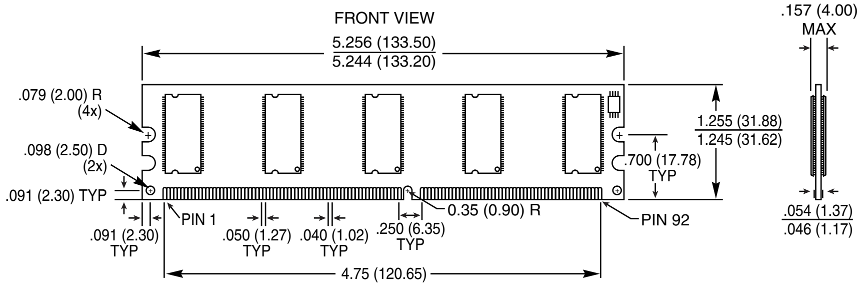

Figure 6.6 A typical 184-pin DDR DIMM. The one shown here is 72-bit, although the dimensions would be the same for 64-bit.

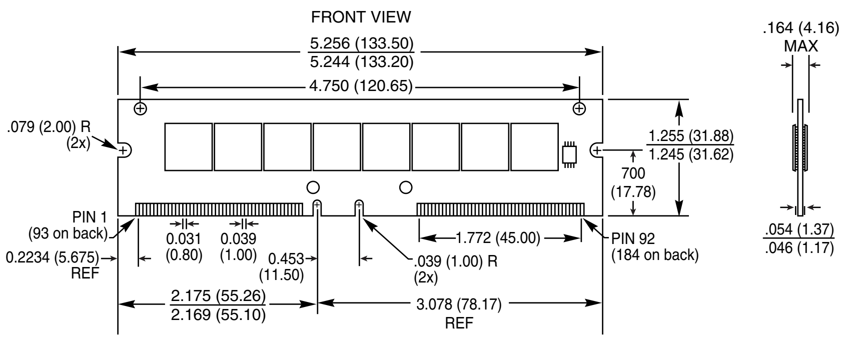

Figure 6.7 A typical 184-pin RIMM. The one shown here is 18-bit, although the dimensions would be the same for 16-bit.

These memory modules are extremely compact, considering the amount of memory they hold, and are available in several capacities and speeds. Table 6.6 lists the various capacities available for SIMMs, DIMMs, and RIMMs.

Table 6.6 SIMM, DIMM, and RIMM Capacities

	30-Pin SIMM Capacities	
Capacity	**Parity SIMM**	**Nonparity SIMM**
256KB	256KB×9	256KB×8
1MB	1MB×9	1MB×8
4MB	4MB×9	4MB×8
16MB	16MB×9	16MB×8
	72-Pin SIMM Capacities	
Capacity	**Parity/ECC SIMM**	**Nonparity SIMM**
1MB	256KB×36	256KB×32
2MB	512KB×36	512KB×32
4MB	1MB×36	1MB×32

Table 6.6 Continued

72-Pin SIMM Capacities		
Capacity	**Parity/ECC SIMM**	**Nonparity SIMM**
8MB	2MB×36	2MB×32
16MB	4MB×36	4MB×32
32MB	8MB×36	8MB×32
64MB	16MB×36	16MB×32
128MB	32MB×36	32MB×32
168/184-Pin DIMM/DDR DIMM Capacities		
Capacity	**Parity/ECC DIMM**	**Nonparity DIMM**
8MB	1MB×72	1MB×64
16MB	2MB×72	2MB×64
32MB	4MB×72	4MB×64
64MB	8MB×72	8MB×64
128MB	16MB×72	16MB×64
256MB	32MB×72	32MB×64
512MB	64MB×72	64MB×64
1024MB	128MB×72	128MB×64
184-Pin RIMM Capacities		
Capacity	**Parity/ECC RIMM**	**Nonparity RIMM**
64MB	32MB×18	32MB×16
128MB	64MB×18	64MB×16
256MB	128MB×18	128MB×16

DRAM SIMMs, DIMMs, and RIMMs of each type and capacity are available in various speed ratings. SIMMs have been available in many speed ratings, ranging from 120ns for some of the slowest to 50ns for some of the fastest available. DIMMs are available in speeds of PC66 (66MHz), PC100 (100MHz), and PC133 (133MHz), whereas the DDR DIMMs are available in PC1600 (1,600MB/sec) and PC2100 (2,100MB/sec) versions.

If a system requires a specific speed, you can almost always substitute faster speeds if the one specified is not available. Generally, no problems occur in mixing module speeds, as long as you use modules equal to or faster than what the system requires. Because there's little price difference between the various speed versions, I often buy faster modules than are necessary for a particular application. This might make them more usable in a future system that could require the faster speed.

Because DIMMs and RIMMs have an onboard ROM that reports their speed and timing parameters to the system, most systems run the memory controller and memory bus at the speed matching the slowest DIMM/RIMM installed. Most DIMMs are SDRAM memory, which means they deliver data in very high-speed bursts using a clocked interface. DDR DIMMs are also SDRAM, but they transfer data two times per clock cycle and thus are twice as fast. SDRAM supports bus speeds of up to 133MHz, whereas DDR DIMMs support speeds of up to 266MHz.

Note

A *bank* is the smallest amount of memory needed to form a single row of memory addressable by the processor. It is the minimum amount of physical memory that is read or written by the processor at one time and usually corresponds to the data bus width of the processor. If a processor has a 64-bit data bus, a bank of memory also is 64-bits wide. If the memory is interleaved or runs dual-channel, a virtual bank is formed that is twice the absolute data bus width of the processor.

You can't always replace a module with a higher capacity unit and expect it to work. Systems might have specific design limitations for the maximum capacity of module they can take. A larger-capacity module works only if the motherboard is designed to accept it in the first place. Consult your system documentation to determine the correct capacity and speed to use.

SIMM Pinouts

Table 6.7 shows the interface connector pinouts for standard 72-pin SIMMs. They also include a special presence detect table that shows the configuration of the presence detect pins on various 72-pin SIMMs. The presence detect pins are used by the motherboard to detect exactly what size and speed SIMM is installed. Industry-standard 30-pin SIMMs do not have a presence detect feature, but IBM did add this capability to its modified 30-pin configuration. Note that all SIMMs have the same pins on both sides of the module.

Table 6.7 Standard 72-Pin SIMM Pinout

Pin	SIMM Signal Name	Pin	SIMM Signal Name	Pin	SIMM Signal Name	Pin	SIMM Signal Name
1	Ground	19	Address Bit 10	37	Parity Data Bit 1	55	Data Bit 11
2	Data Bit 0	20	Data Bit 4	38	Parity Data Bit 3	56	Data Bit 27
3	Data Bit 16	21	Data Bit 20	39	Ground	57	Data Bit 12
4	Data Bit 1	22	Data Bit 5	40	Column Address Strobe 0	58	Data Bit 28
5	Data Bit 17	23	Data Bit 21	41	Column Address Strobe 2	59	+5 Vdc
6	Data Bit 2	24	Data Bit 6	42	Column Address Strobe 3	60	Data Bit 29
7	Data Bit 18	25	Data Bit 22	43	Column Address Strobe 1	61	Data Bit 13
8	Data Bit 3	26	Data Bit 7	44	Row Address Strobe 0	62	Data Bit 30
9	Data Bit 19	27	Data Bit 23	45	Row Address Strobe 1	63	Data Bit 14
10	+5 Vdc	28	Address Bit 7	46	Reserved	64	Data Bit 31
11	Presence Detect 5	29	Address Bit 11	47	Write Enable	65	Data Bit 15
12	Address Bit 0	30	+5 Vdc	48	ECC Optimized	66	EDO
13	Address Bit 1	31	Address Bit 8	49	Data Bit 8	67	Presence Detect 1
14	Address Bit 2	32	Address Bit 9	50	Data Bit 24	68	Presence Detect 2
15	Address Bit 3	33	Address Bit 12	51	Data Bit 9	69	Presence Detect 3
16	Address Bit 4	34	Address Bit 13	52	Data Bit 25	70	Presence Detect 4
17	Address Bit 5	35	Parity Data Bit 2	53	Data Bit 10	71	Reserved
18	Address Bit 6	36	Parity Data Bit 0	54	Data Bit 26	72	Ground

Notice that the 72-pin SIMMs use a set of four or five pins to indicate the type of SIMM to the motherboard. These presence detect pins are either grounded or not connected to indicate the type of SIMM to the motherboard. Presence detect outputs must be tied to the ground through a zero-ohm resistor or jumper on the SIMM—to generate a high logic level when the pin is open or a low logic level when the pin is grounded by the motherboard. This produces signals that can be decoded by the memory interface logic. If the motherboard uses presence detect signals, a POST (power on self test) procedure can determine the size and speed of the installed SIMMs and adjust control and addressing signals automatically. This enables the memory size and speed to be autodetected.

Note

In many ways, the presence detect pin function is similar to the industry-standard DX coding used on modern 35mm film rolls to indicate the ASA (speed) rating of the film to the camera. When you drop the film into the camera, electrical contacts can read the film's speed rating via an industry-standard configuration.

Table 6.8 shows the Joint Electronic Devices Engineering Council (JEDEC) industry-standard presence detect configuration listing for the 72-pin SIMM family. JEDEC is an organization of U.S. semiconductor manufacturers and users that sets package outline dimension and other standards for chip and module packages.

Table 6.8 Presence Detect Pin Configurations for 72-Pin SIMMs

Size	Speed	Pin 67	Pin 68	Pin 69	Pin 70	Pin 11

16MB	70ns	Gnd	—	Gnd	—	Gnd
16MB	60ns	Gnd	—	—	—	Gnd
16MB	50ns	Gnd	—	Gnd	Gnd	Gnd
32MB	80ns	—	Gnd	—	Gnd	Gnd

Table 6.8 Continued

Size	Speed	Pin 67	Pin 68	Pin 69	Pin 70	Pin 11
32MB	70ns	—	Gnd	Gnd	—	Gnd
32MB	60ns	—	Gnd	—	—	Gnd
32MB	50ns	—	Gnd	Gnd	Gnd	Gnd

— = No connection (open)
Gnd = Ground
Pin 67 = Presence detect 1
Pin 68 = Presence detect 2
Pin 69 = Presence detect 3
Pin 70 = Presence detect 4
Pin 11 = Presence detect 5

Unfortunately, unlike the film industry, not everybody in the computer industry follows established standards. As such, presence detect signaling is not a standard throughout the PC industry. Different system manufacturers sometimes use different configurations for what is expected on these four pins. Compaq, IBM (mainly PS/2 systems), and Hewlett-Packard are notorious for this type of behavior. Many of the systems from these vendors require special SIMMs that are basically the same as standard 72-pin SIMMs, except for special presence detect requirements. Table 6.9 shows how IBM defines these pins.

Table 6.9 72-Pin SIMM Presence Detect Pins

67	68	69	70	SIMM Type	IBM Part Number
—	—	—	—	Not a valid SIMM	n/a
Gnd	—	—	—	1MB 120ns	n/a
—	Gnd	—	—	2MB 120ns	n/a
Gnd	Gnd	—	—	2MB 70ns	92F0102
—	—	Gnd	—	8MB 70ns	64F3606
Gnd	—	Gnd	—	Reserved	n/a

Gnd = Ground *SPD = Serial presence detect* *NC = No connection*

The DIMM uses a completely different type of presence detect called *serial presence detect (SPD)*. It consists of a small EEPROM or Flash memory chip on the DIMM that contains specially formatted data indicating the DIMM's features. This serial data can be read via the serial data pins on the DIMM, and it enables the motherboard to autoconfigure to the exact type of DIMM installed.

DIMMs can come in several varieties, including unbuffered or buffered and 3.3V or 5V. Buffered DIMMs have additional buffer chips on them to interface to the motherboard. Unfortunately, these buffer chips slow down the DIMM and are not effective at higher speeds. For this reason, all PC systems use unbuffered DIMMs. The voltage is simple—DIMM designs for PCs are almost universally 3.3V. If you install a 5V DIMM in a 3.3V socket, it would be damaged, but fortunately, keying in the socket and on the DIMM prevents that.

Modern PC systems use only unbuffered 3.3V DIMMs. Apple and other nonPC systems can use the buffered 5V versions. Fortunately, the key notches along the connector edge of a DIMM are spaced differently for buffered/unbuffered or 3.3V/5V DIMMs, as shown in Figure 6.8. This prevents inserting a DIMM of the wrong type into a given socket.

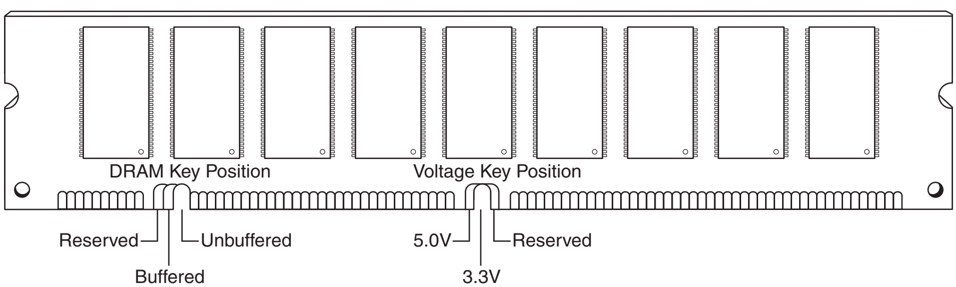

Figure 6.8 168-pin DRAM DIMM notch key definitions.

DDR DIMM Pinouts

Table 6.11 shows the pinout configuration of a 184-pin DDR SDRAM DIMM. Note again that the pins on each side of the DIMM are different.

Table 6.11 184-Pin DDR DIMM Pinouts

DDR DIMMs use a single key notch to indicate voltage, as shown in Figure 6.9.

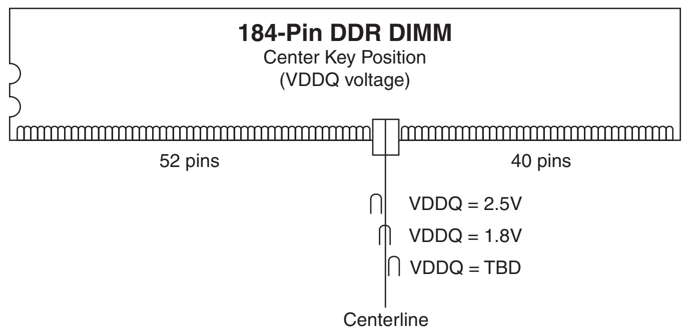

Figure 6.9 184-pin DDR SDRAM DIMM keying.

184-pin DDR DIMMs use two notches on each side to enable compatibility with both low- and high-profile latched sockets. Note that the key position is offset with respect to the center of the DIMM to prevent inserting it backward in the socket. The key notch is positioned to the left, centered, or to the right of the area between pins 52 and 53. This is used to indicate the I/O voltage for the DDR DIMM and to prevent installing the wrong type into a socket that might damage the DIMM.

RIMM Pinouts

RIMM modules and sockets are gold-plated and designed for 25 insertion/removal cycles. Each RIMM has 184 pins, split into two groups of 92 pins on opposite ends and sides of the module. The pinout of the RIMM is shown in Table 6.12.

Note

RIMMs are designed for only 25 insertion and removal cycles, so if you are installing and removing them more times than that, you can compromise the gold plating on the module or connector. It is not likely that anybody would install or remove memory that many times, but it is worth noting.

RIMMs are keyed with two notches in the center. This prevents a backward insertion and prevents the wrong type (voltage) RIMM from being used in a system. Currently, all RIMMs run on 2.5V, but future versions might run on less. To allow for these new types of RIMMs, three keying options are possible in the design (see Figure 6.10). The left key (indicated as “DATUM A” in Figure 6.8) is fixed in position, but the center key can be in three different positions spaced 1mm or 2mm to the right, indicating different types of RIMMs. The current default is option A, as shown in Figure 6.10 and Table 6.13, which corresponds to 2.5V operation.

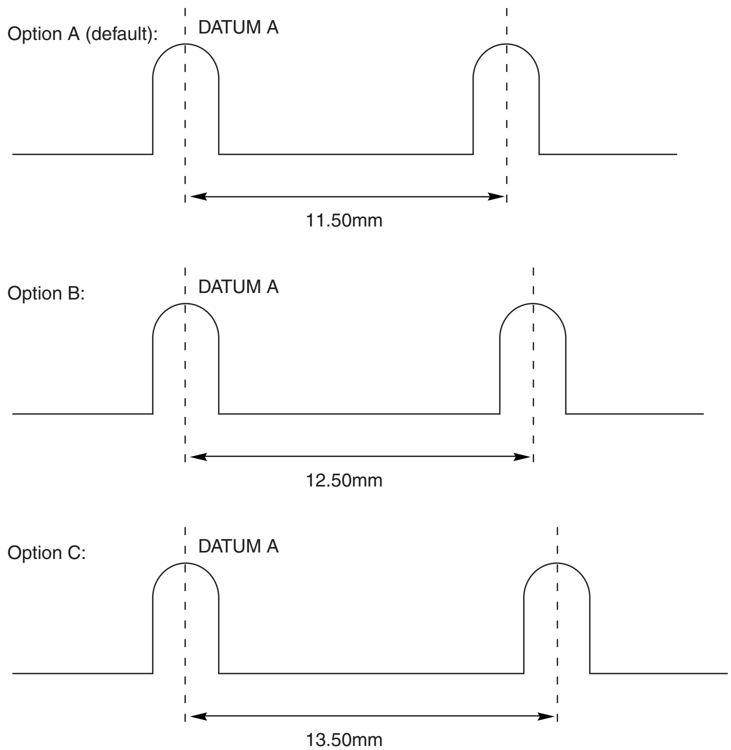

Figure 6.10 RIMM keying options.

Table 6.13 Possible Keying Options for RIMMs

Option	Notch Separation	Description
A	11.5mm	2.5V RIMM
B	12.5mm	Reserved
C	13.5mm	Reserved

RIMMs incorporate an SPD device, which is essentially a Flash ROM onboard. This ROM contains information about the RIMM's size and type, including detailed timing information for the memory controller. The memory controller automatically reads the data from the SPD ROM to configure the system to match the RIMMs installed.

Figure 6.11 shows a typical PC RIMM installation. The RDRAM controller and clock generator are typically in the motherboard chipset North Bridge component. As you can see, the Rambus memory channel flows from the memory controller through each of up to three RIMM modules in series. Each module contains 4, 8, 16, or more RDRAM devices (chips), also wired in series, with an onboard SPD ROM for system configuration. Any RIMM sockets without a RIMM installed must have a continuity module, shown in the last socket in Figure 6.11. This enables the memory bus to remain continuous from the controller through each module (and, therefore, each RDRAM device on the module) until the bus finally terminates on the motherboard. Note how the bus loops from one module to another. For timing purposes, the first RIMM socket must be 6 inches or less from the memory controller, and the entire length of the bus must not be more than it would take for a signal to go from one end to another in four data clocks, or about 5ns.

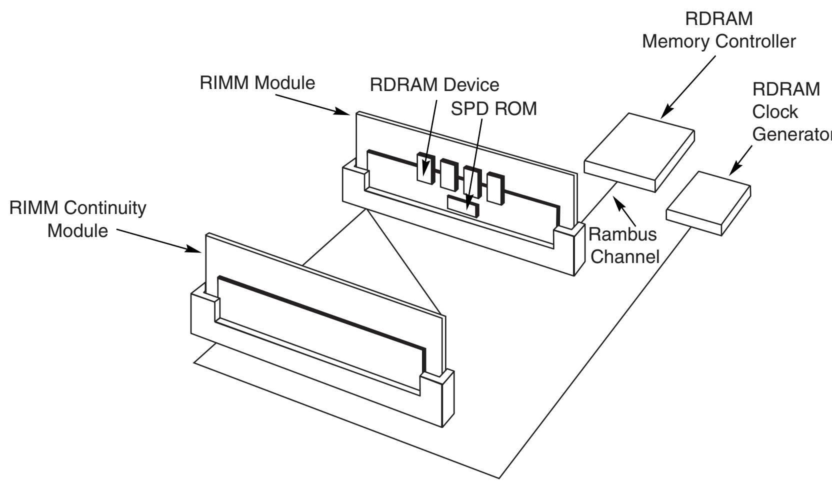

Figure 6.11 Typical RDRAM bus layout showing a RIMM and one continuity module.

Interestingly, Rambus does not manufacture the RDRAM devices (the chips) or the RIMMs; that is left to other companies. Rambus is merely a design company, and it has no chip fabs or manufacturing facilities of its own. It licenses its technology to other companies who then manufacture the devices and modules.

Physical RAM Capacity and Organization

Several types of memory chips have been used in PC system motherboards. Most of these chips are single-bit–wide chips, available in several capacities.

Note that chip capacity normally goes up by factors of four because the dies that make up the chips are square. When they increase capacity, this normally results in four times more transistors and four times more capacity. Most modern SIMMs and DIMMs use 16Mbit–256Mbit chips onboard.

Figure 6.12 shows the markings on a typical memory chip from Micron Technologies, one of the most popular chip and module manufacturers. Many memory manufacturers use similar schemes for numbering their chips; however, if you are really trying to identify a particular chip, it is best to consult the manufacturer catalog for more information.

The -75 marking corresponds to the chip speed in nanoseconds, in this case a 7.5 nanosecond or 133MHz designation.

The part number usually contains a clue about the chip's type and capacity. The chip here is MT48LC8M8A2TG-75L. This decodes as

MT = Micron Technologies

48 = SDRAM

LC = 3.3V CMOS

8M8 = 8 million rows deep × 8 bits wide

A2 = Device version

TG = TSOP (thin small outline package)

-75 = 7.5 ns (133MHz) rating

L = Low power

Note

Markings vary from manufacturer to manufacturer. The example shown here is for illustrative purposes only.

Because this chip is 8 bits wide, I'd expect to see either 8 or 16 of them on a DIMM to make up the 64 bits of width for the complete DIMM. If 16 chips were used, this would be known as a *double-sided* DIMM, and the chips would be arranged in a logically stacked form where the two banks of 8MB×8 chips work together as if they were a single bank of 16MB×8 chips. If 8 of these chips were on a DIMM, it would be 8MB×64 bits, which is the same as saying 8MB×8 bytes, which is the same as calling it a 64MB DIMM. If there were 16 of these chips, it would be a 128MB double-sided DIMM, and if there were either 9 or 18 of these chips, it would be a 72-bit wide DIMM with parity/ECC support.

Most chips also feature a four-digit number separate from the part number, which indicates the date of manufacture by week and day. For example, 0021 indicates the chip was made in the 21st week of 2000. To further decode the chip, contact the manufacturer or chip vendor for its catalog information.

SIMMs and DIMMs also have part numbers that can be difficult to decode. Unfortunately, no industry standard exists for numbering these modules, so you must contact the manufacturer if you want to decode the numbers.

Sometimes you can't find any writing on the SIMM or DIMM that tells you the capacity or other information. In that case, just look up the chip part numbers on the chip manufacturer's Web site, and from there you should be able to figure out what it is (see Figure 6.13).

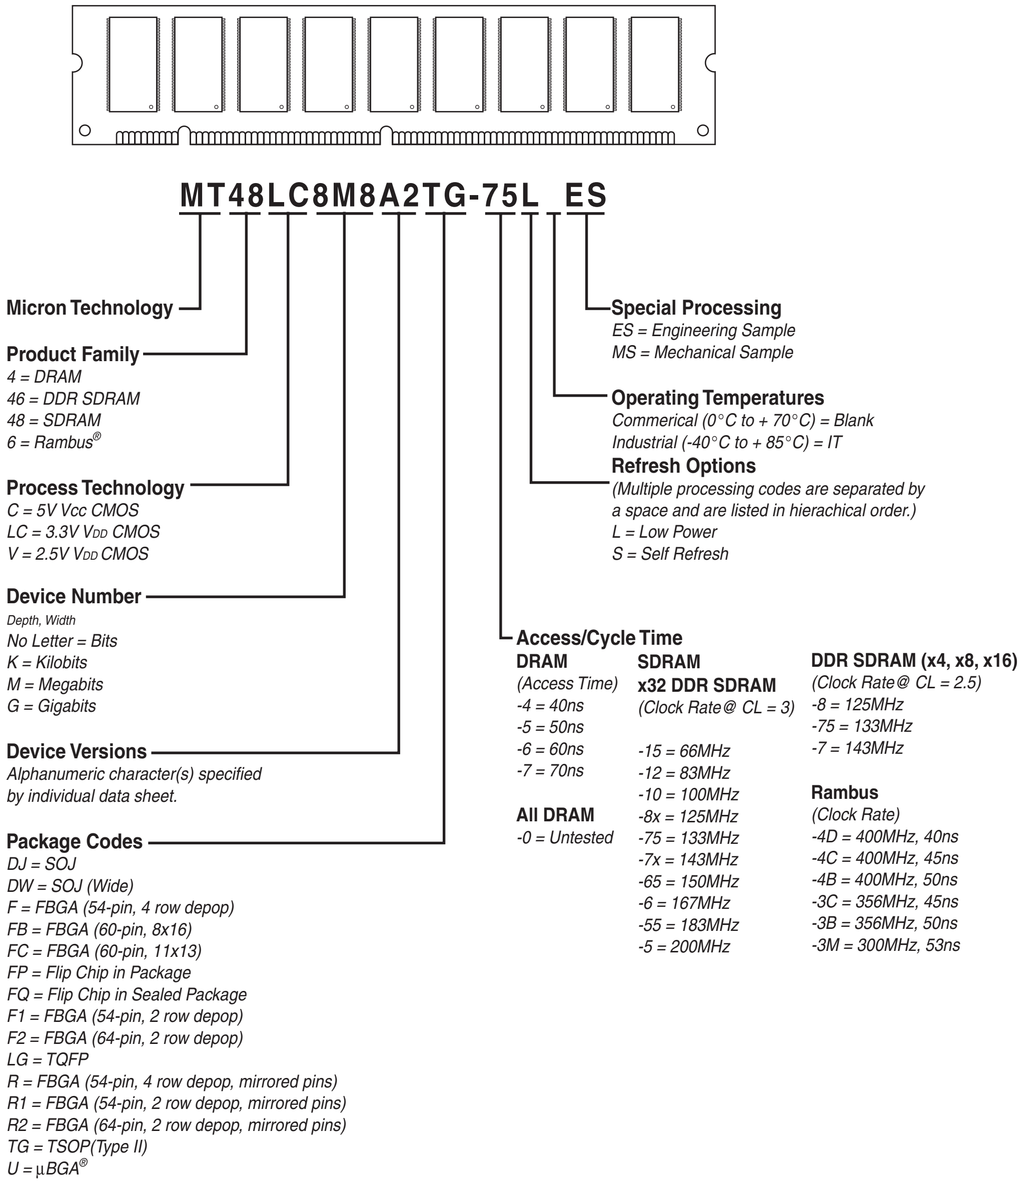

Figure 6.12 The markings on a typical memory chip (Micron shown).

The fact that I can't decipher the information on the stickers about the DIMM is not a problem, as long as I can read the chip part numbers.

The chips carry the Hyundai (HY) logo, with a part number of HY57V651620-TC10. I found the data sheet for these chips at the Hyundai Memory Web site. I can't tell who made the actual DIMM; at first I suspected Hyundai might have made it because of the HY-3U1606 number on the left side, but I can't find any corresponding information in the Hyundai catalog that matches this designation. No matter; I can still deduce all the information I need about this module by looking at the chip information.

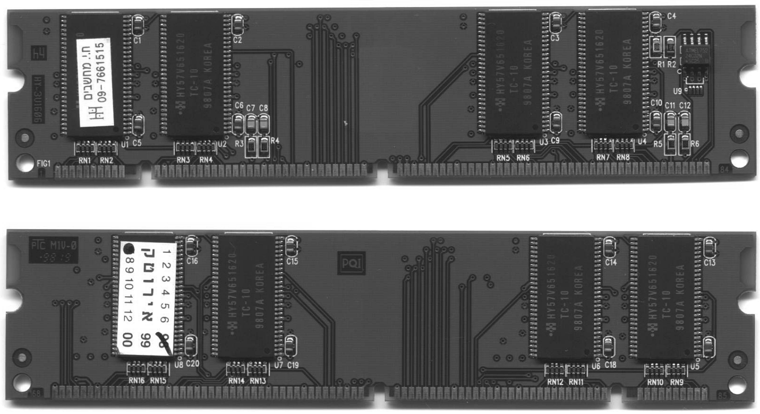

Figure 6.13 DIMM front/rear view with indecipherable markings indicating part number, capacity, or speed.

According to the data sheet for the chips on this DIMM, these are 10ns chips, which, although technically rated 100MHz, would classify this as a 66MHz SDRAM DIMM (PC66). If they were 8ns (125MHz) chips, this would be a PC100 DIMM, and if 7.5ns, this would be a PC133 DIMM. These are 64Mbit chips, organized as 4MB×16 (rows by columns). There are four chips on one side, resulting in a full 64-bit wide bank of 4MB×64 bits (4MB×8 bytes or 32MB total). The other side contains the same number of chips, which would be electronically or logically "stacked" to double the depth (number of rows). This is because DIMMs can be only 64 bits wide, resulting in a total of 8MB×64 bits, which is 8MB×8 bytes, which is 64MB total. The additional tiny Atmel brand chip on the right side is the serial EPROM, which contains the data about this DIMM that can be read by the motherboard to configure the chipset memory controllers. Because there are no additional memory chips, this DIMM lacks the additional 8 bits of width to make it a 72-bit wide ECC DIMM.

So, by deciphering the chip part numbers and adding things up, I have figured out that this is a 64MB, double-sided, non-ECC, PC66 SDRAM DIMM.

Memory Banks

Memory chips (DIPs, SIMMs, SIPPs, and DIMMs) are organized in banks on motherboards and memory cards. You should know the memory bank layout and position on the motherboard and memory cards.

You need to know the bank layout when adding memory to the system. In addition, memory diagnostics report error locations by byte and bit addresses, and you must use these numbers to locate which bank in your system contains the problem.

The banks usually correspond to the data bus capacity of the system's microprocessor. Table 6.14 shows the widths of individual banks based on the type of PC.

Table 6.14 Memory Bank Widths on Various Systems

Processor	Data Bus	Memory Bank Size (No Parity)	Memory Bank Size (Parity)	30-Pin SIMMs per Bank	72-Pin SIMMs per Bank	168-Pin DIMMs per Bank
8088	8-bit	8 bits	9 bits	1	n/a	n/a
8086	16-bit	16 bits	18 bits	2	n/a	n/a
286	16-bit	16 bits	18 bits	2	n/a	n/a
386SX, SL, SLC	16-bit	16 bits	18 bits	2	n/a	n/a
486SLC, SLC2	16-bit	16 bits	18 bits	2	n/a	n/a
386DX	32-bit	32 bits	36 bits	4	1	n/a
486SX, DX, DX2, DX4, 5x86	32-bit	32 bits	36 bits	4	1	n/a
Pentium, K6 series	64-bit	64 bits	72 bits	8	2	1
PPro, PII, Celeron, PIII, P4, Athlon/Duron	64-bit	64 bits	72 bits	8	2	1

The number of bits for each bank can be made up of single chips, SIMMs, or DIMMs. Modern systems don't use individual chips; instead, they use only SIMMs or DIMMs. If the system has a 16-bit processor, such as a 386SX, it probably uses 30-pin SIMMs and has two SIMMs per bank. All the SIMMs in a single bank must be the same size and type.

A 486 system requires four 30-pin SIMMs or one 72-pin SIMM to make up a bank. A single 72-pin SIMM is 32 bits wide, or 36 bits wide if it supports parity. You can often tell whether a SIMM supports parity by counting its chips. To make a 32-bit SIMM, you could use 32 individual 1-bit–wide chips, or you could use eight individual 4-bit–wide chips to make up the data bits. If the system uses parity, four extra bits are required (36 bits total), so you would see one more 4-bit–wide or four individual 1-bit–wide chips added to the bank for the parity bits.

As you might imagine, 30-pin SIMMs are less than ideal for 32-bit or 64-bit systems (that is, 486 or Pentium) because you must use them in increments of four or eight per bank! Because these SIMMs are available in 1MB, 4MB, and 16MB capacities today, this means that a single bank of 30-pin SIMMs in a 486 system would be 4MB, 16MB, or 64MB; for a Pentium system, this would be 8MB, 32MB, or 128MB of memory, with no in-between amounts. Using 30-pin SIMMs in 32- and 64-bit systems artificially constrains memory configurations, and such systems are not recommended. If a 32-bit system (such as any PC with a 486 processor) uses 72-pin SIMMs, each SIMM represents a separate bank, and the SIMMs can be added or removed on an individual basis rather than in groups of four, as would be required with 30-pin SIMMs. This makes memory configuration much easier and more flexible. In modern 64-bit systems that use SIMMs, two 72-pin SIMMs are required per bank.

DIMMs are ideal for Pentium and higher systems because the 64-bit width of the DIMM exactly matches the 64-bit width of the Pentium processor data bus. This means that each DIMM represents an individual bank, and they can be added or removed one at a time.

The physical orientation and numbering of the SIMMs or DIMMs used on a motherboard is arbitrary and determined by the board's designers, so documentation covering your system or card comes in handy. You can determine the layout of a motherboard or an adapter card through testing, but that takes time and might be difficult, particularly after you have a problem with a system.

Memory Module Speed

When you replace a failed memory module or install a new module as an upgrade, you typically must install a module of the same type and speed as the others in the system. You can substitute a module with a different (faster) speed but only if the replacement module's speed is equal to or faster than that of the other modules in the system.

Some people have had problems when "mixing" modules of different speeds. With the wide variety of motherboards, chipsets, and memory types, few ironclad rules exist. When in doubt as to which speed module to install in your system, consult the motherboard documentation for more information.

Substituting faster memory of the same type doesn't result in improved performance if the system still operates the memory at the same speed. Systems that use DIMMs or RIMMs can read the speed and timing features of the module from a special SPD ROM installed on the module and then set chipset (memory controller) timing accordingly. In these systems, you might see an increase in performance by installing faster modules, to the limit of what the chipset will support.

To place more emphasis on timing and reliability, there are Intel and JEDEC standards governing memory types that require certain levels of performance. Intel, for example, has created the PC66, PC100, and PC133 standards supported by many newer chipsets. These are standards for certifying that memory modules perform within Intel's timing and performance guidelines. At 100MHz or higher, there is not much "forgiveness" or slop allowed in memory timing.

The same common symptoms result when the system memory has failed or is simply not fast enough for the system's timing. The usual symptoms are frequent parity check errors or a system that does not operate at all. The POST might report errors, too. If you're unsure of which chips to buy for your system, contact the system manufacturer or a reputable chip supplier.

▶▶ See "Parity Checking," p. 445.

Gold Versus Tin

Many people don't understand the importance of the memory module electrical contacts in a computer system. Modules (SIMMs, DIMMs, and RIMMs) are available in gold- or tin-plated contact form. I initially thought that gold contact modules were the best way to go for reliability in all situations, but that is not true. To have the most reliable system, you must install modules with gold-plated contacts into gold-plated sockets and modules with tin-plated contacts into only tin-plated sockets.

If you don't heed this warning and install memory with gold-plated contacts into tin sockets or vice versa, you will have problems with memory errors and reliability in the long run. In my experiences, they occur six months to one year after installation. I have encountered this problem several times in my own systems and in several systems I have serviced. I have even been asked to assist one customer in a lawsuit as an expert witness. The customer had bought several hundred machines from a vendor, and severe memory failures began appearing in most of the machines approximately a year after delivery. The cause was traced to dissimilar metals between the memory modules and sockets (gold-plated contact SIMMs in tin-plated contact sockets, in this case). The vendor refused to replace the SIMMs with tin-plated versions, hence the lawsuit.

Most systems using 72-pin SIMMs have tin-plated sockets, so they must have tin-plated SIMM memory installed. Studies done by the connector manufacturers, such as AMP, show that a type of corrosion called *fretting* occurs when tin comes in pressure contact with gold or any other metal. With fretting corrosion, tin oxide transfers to the harder gold surface, eventually causing a high-resistance connection. This happens whenever gold comes into contact with tin, no matter how thick or thin the gold coating is. Over time, depending on the environment, fretting corrosion can and will cause high resistance at the contact point and thus cause memory errors.

You might think tin makes a poor connector material because it readily oxidizes. Even so, electrical contact is easily made between two tin surfaces under pressure because the oxides on the softer tin surfaces bend and break, ensuring contact. In most memory modules, the contacts are under fairly high pressure when the modules are installed.

When tin and gold come into contact, because one surface is hard, the oxidation builds up and does not break easily under pressure. Increased contact resistance ultimately results in memory failures.

The connector manufacturer AMP has published several documents from the AMP Contact Physics Research Department that discuss this issue, but two are the most applicable. One is titled "Golden Rules: Guidelines for the Use of Gold on Connector Contacts," and the other is called "The Tin Commandments: Guidelines for the Use of Tin on Connector Contacts." Both can be downloaded in PDF form from the AMP Web site. Commandment Number Seven from the Tin Commandments specifically states "7. Mating of tin-coated contacts to gold-coated contacts is not recommended." For further technical details, you can contact Intel or AMP.

Certainly, the best type of arrangement is having gold-plated modules installed in gold-plated sockets. Most systems using DIMMs or RIMMs are designed this way.

If you have mixed metals in your memory now, the correct solution is to replace the memory modules with the appropriate contact type to match the socket. Another much less desirable solution is to wait until problems appear (about six months to a year, in my experience), and then remove the modules, clean the contacts, reinstall, and repeat the cycle. This is probably fine if you are an individual with one or two systems, but it is not fine if you are maintaining hundreds of systems. If your system does not feature parity or ECC memory (most systems sold today do not), when the problems do occur, you might not be able to immediately identify them as memory related (General Protection Faults, crashes, file and data corruption, and so on).

One problem with cleaning is that the hard tin oxide deposits that form on the gold surface are difficult to remove and often require abrasive cleaning (by using an eraser or a crocus cloth, for example). This should never be done dry because it generates static discharges that can damage the chips. Instead, use a contact cleaner to lubricate the contacts; wet contacts minimize the potential for static discharge damage when rubbing the eraser or other abrasive on the surface.

To further prevent this problem from occurring, I highly recommend using a liquid contact enhancer and lubricant called Stabilant 22 from D.W. Electrochemicals when installing SIMMs or DIMMs. Its Web site has a detailed application note on this subject if you are interested in more technical details; see the Vendor List on the CD-ROM.

Some people have accused me of being too picky by insisting that the memory match the socket. On several occasions, I have returned either memory or motherboards because the vendor putting them together did not have a clue that this is a problem. When I tell some people about it, they tell me they have a lot of PCs with mixed metal contacts that run fine and have been doing so for many years.

Of course, that is certainly a poor argument against sound engineering practices. Many people are running SCSI buses that are way too long, with improper termination, and they say it runs "fine." Parallel port cables are by the spec limited to 10 feet, yet I see many have longer cables, which they claim work "fine." The IDE cable limit is 18 inches; that spec is violated and people get away with it, saying their drive runs just "fine." I see cheap, crummy power supplies that put out noise, ripple, and loosely regulated voltages, and I have even measured up to 69 volts AC of ground leakage, and yet the systems appeared to be running "fine." I have encountered numerous systems without proper CPU heatsinks, or in which the active heatsink (fan) was seized, and the system ran "fine." This reminds me of when Johnny Carson would interview 100-year-old people and often got them to admit that they drank heavily and smoked cigarettes every day, as if those are good practices that ensure longevity!

The truth is I am often amazed at how poorly designed or implemented some systems are, and yet they do seem to work…for the most part. The occasional lockup or crash is just written off by the user as “that’s they way they all are.” All except my systems, of course. In my systems, I adhere to proper design and engineering practices. In fact, I am often guilty of engineering or specifying overkill into things. Although it adds to the cost, they do seem to run better because of it.

In other words, what one individual can “get away” with does not change the laws of physics. It does not change the fact that for those supporting many systems or selling systems where the maximum in reliability and service life is desired, the gold/tin issue does matter.

Another issue that was brought to my attention was the thickness of the gold on the contacts; people are afraid that it is so thin, it will wear off after one or two insertions. Certainly, the choice of gold coating thickness depends on the durability required by the application; because of gold’s high cost, it is prudent to keep the gold coating thickness as low as is appropriate for the durability requirements.

To improve durability, a small amount of cobalt or nickel added to the gold usually hardens the gold coatings. Such coatings are defined as “hard gold” and produce coatings with a low coefficient of friction and excellent durability characteristics. Hard gold-coated contacts can generally withstand hundreds to thousands of durability cycles without failing. Using an underlayer with a hardness value greater than that of gold alone that provides additional mechanical support can enhance the durability of hard gold coatings. Nickel is generally recommended as an underlayer for this purpose. Special electronic contact lubricants or enhancers, such as Stabilant 22 from D.W. Electrochemicals, are also effective at increasing the durability of gold coatings. Generally, lubrication can increase the durability of a gold contact by an order of magnitude. These and other chemicals are discussed in more detail in Chapter 24, “PC Diagnostics, Testing, and Maintenance.”

Increasing the thickness of a hard gold coating increases durability. The following laboratory results were obtained by AMP for the wear-through of a hard gold coating to the 1.3 micron (50 microinch) thick nickel underplate. The following data is for a 0.635cm. (0.250 in.) diameter ball wiped a distance of 1.27cm. (0.500 in.) under a normal force of 100 grams for each cycle.

Thickness Microns	Thickness Microinch	Cycles to Failure
0.4	15	200
0.8	30	1000
1.3	50	2000

As you can see from this table, an 0.8 micron (30 microinches) coating of hard gold results in durability that is more than adequate for most connector applications because it allows 1,000 insertion and removal cycles before wearing through. I studied the specification sheets for DIMM and SIMM sockets produced by AMP and found that its gold-plated sockets come mostly as .000030 (30 microinches) thick gold over .000050 (50 microinches) thick nickel in the contact area. As far as I can determine, the coating on virtually all memory module contacts would be similar in thickness, allowing for the same durability.

AMP also has a few gold-plated sockets with specifications of .001020-thick (1,020 microinches) gold over .001270-thick (1,270 microinches) nickel. I’d guess that the latter sockets were for devices such as SIMM testers, in which many insertions were expected over the life of the equipment. They could also be used in high-vibration or high-humidity environments.

For reference, all its tin-contact SIMM and DIMM sockets have the following connector plating specifications: .000030 (30 microinches) minimum thick tin on mating edge over .000050 (50 microinches) minimum thick nickel on entire contact.

The bottom line is that the thickness of the coating in current module sockets and modules is not an issue for the expected use of these devices. The thickness of the plating used is also not relevant to the tin versus gold matability issue. The only drawback to a thinner gold plating is that it will wear after fewer insertion/removal cycles, exposing the nickel underneath and allowing the onset of fretting corrosion.

In my opinion, this tin/gold issue is even more important for those using DIMMs and RIMMs, for two reasons. With SIMMs, you really have two connections for each pin (one on each side of the module), so if one of them goes high resistance, it will not matter; there is a built-in redundancy. With DIMMs and RIMMs, you have many, many more connections (168 or 184 versus 72) and no redundant connections. The chance for failure is much greater. Also, DIMMs and RIMMs run much faster, at speeds of up to 800MHz, where the timing is down in the single-digit nanosecond range. At these speeds, the slightest additional resistance in the connection causes problems.

Bottom line: Definitely don't mix metal types, but for the utmost in reliability for systems using DIMMs or RIMMs, be sure both the motherboard sockets as well as the modules themselves have gold-plated contacts. You usually can tell easily because tin is silver-colored, whereas gold is, well, gold-colored.

Parity and ECC

Part of the nature of memory is that it inevitably fails. These failures are usually classified as two basic types: hard fails and soft errors.

The best understood are *hard fails*, in which the chip is working and then, because of some flaw, physical damage, or other event, becomes damaged and experiences a permanent failure. Fixing this type of failure normally requires replacing some part of the memory hardware, such as the chip, SIMM, or DIMM. Hard error rates are known as *HERs*.

The other more insidious type of failure is the *soft error*, which is a nonpermanent failure that might never recur or could occur only at infrequent intervals. (Soft fails are effectively "fixed" by powering the system off and back on.) Soft error rates are known as *SERs*.

About 20 years ago, Intel made a discovery about soft errors that shook the memory industry. It found that alpha particles were causing an unacceptably high rate of soft errors or single event upsets (SEUs, as they are sometimes called) in the 16KB DRAMs that were available at the time. Because alpha particles are low-energy particles that can be stopped by something as thin and light as a sheet of paper, it became clear that for alpha particles to cause a DRAM soft error, they would have to be coming from within the semiconductor material. Testing showed trace elements of thorium and uranium in the plastic and ceramic chip packaging materials used at the time. This discovery forced all the memory manufacturers to evaluate their manufacturing process to produce materials free from contamination.

Today, memory manufacturers have all but totally eliminated the alpha-particle source of soft errors. Many people believed that was justification for the industry trend to drop parity checking. The argument is that, for example, a 16MB memory subsystem built with 4MB technology would experience a soft error caused by alpha particles only about once every 16 years! The real problem with this thinking is that it is seriously flawed, and many system manufacturers and vendors were coddled into removing parity and other memory fault-tolerant techniques from their systems even though soft errors continue to be an ongoing problem. More recent discoveries prove that alpha particles are now only a small fraction of the cause of DRAM soft errors!

As it turns out, the biggest cause of soft errors today are cosmic rays. IBM researchers began investigating the potential of terrestrial cosmic rays in causing soft errors similar to alpha particles. The difference is that cosmic rays are very high-energy particles and can't be stopped by sheets of paper or other more powerful types of shielding. The leader in this line of investigation was Dr. J.F. Ziegler of the IBM Watson Research Center in Yorktown Heights, New York. He has produced landmark research into understanding cosmic rays and their influence on soft errors in memory.

One example of the magnitude of the cosmic ray soft-error phenomenon demonstrated that with a certain sample of non-IBM DRAMs, the SER at sea level was measured at 5950 FIT (failures in time, which is measured at one billion hours) per chip. This was measured under real-life conditions with the benefit of millions of device hours of testing. In an average system, this would result in a soft error occurring every six months or less. In power-user or server systems with a larger amount of memory, it could mean one or more errors per month! When the exact same test setup and DRAMs were moved to an underground vault shielded by more than 50 feet of rock, thus eliminating all cosmic rays, absolutely no soft errors were recorded. This not only demonstrates how troublesome cosmic rays can be, but it also proves that the packaging contamination and alpha-particle problem has indeed been solved.

Cosmic-ray–induced errors are even more of a problem in SRAMs than DRAMS because the amount of charge required to flip a bit in an SRAM cell is less than is required to flip a DRAM cell capacitor. Cosmic rays are also more of a problem for higher-density memory. As chip density increases, it becomes easier for a stray particle to flip a bit. It has been predicted by some that the soft error rate of a 64MB DRAM will be double that of a 16MB chip, and a 256MB DRAM will have a rate four times higher.

Unfortunately, the PC industry has largely failed to recognize this cause of memory errors. Electrostatic discharge, power surges, or unstable software can much more easily explain away the random and intermittent nature of a soft error, especially right after a new release of an operating system or major application.

Studies have shown that the soft error rate for ECC systems is on the order of 30 times greater than the hard error rate. This is not surprising to those familiar with the full effects of cosmic ray–generated soft errors. There is now data suggesting that some 16MB DRAM chip designs will actually experience soft errors numbering in the 24,000 FIT range. This would result in a soft error about once a month for most systems today!

Although cosmic rays and other radiation events are the biggest cause of soft errors, others can be caused by the following:

- *Power glitches or noise on the line*. This can be caused by a defective power supply in the system or by defective power at the outlet.
- *Incorrect type or speed rating*. The memory must be the correct type for the chipset and match the system access speed.
- *RF (radio frequency) interference*. Caused by radio transmitters in close proximity to the system, which can generate electrical signals in system wiring and circuits.
- *Static discharges*. Causes momentary power spikes, which alter data.
- *Timing glitches*. Data doesn't arrive at the proper place at the proper time, causing errors. Often caused by improper settings in the BIOS Setup, by memory that is rated slower than the system requires, or by overclocked processors and other system components.

Most of these problems don't cause chips to permanently fail (although bad power or static can damage chips permanently), but they can cause momentary problems with data.

How can you deal with these errors? Just ignoring them is certainly not the best way to deal with them, but unfortunately that is what many system manufacturers and vendors are doing today. The best way to deal with this problem is to increase the system's fault tolerance. This means implementing ways of detecting and possibly correcting errors in PC systems. Three basic levels and techniques are used for fault tolerance in modern PCs:

- Nonparity
- Parity
- ECC

Nonparity systems have no fault tolerance at all. The only reason they are used is because they have the lowest inherent cost. No additional memory is necessary, as is the case with parity or ECC techniques. Because a parity-type data byte has 9 bits versus 8 for nonparity, memory cost is 12.5% higher. Also, the nonparity memory controller is simplified because it does not need the logic gates to calculate parity or ECC check bits. Portable systems that place a premium on minimizing power might benefit from the reduction in memory power resulting from fewer DRAM chips. Finally, the memory system data bus is narrower, which reduces the amount of data buffers. The statistical probability of memory failures in a modern office desktop computer is now estimated at about one error every few months. Errors will be more or less frequent depending on how much memory you have.

This error rate might be tolerable for low-end systems that are not used for mission-critical applications. In this case, their extreme market cost sensitivity probably can't justify the extra cost of parity or ECC memory, and such errors then must be tolerated.

At any rate, having no fault tolerance in a system is simply gambling that memory errors are unlikely. You further gamble that if they do occur, memory errors will result in an inherent cost less than the additional hardware necessary for error detection. However, the risk is that these memory errors can lead to serious problems. A memory error in a calculation could cause the wrong value to go into a bank check. In a server, a memory error could force a system to hang and bring down all LAN-resident client systems with subsequent loss of productivity. Finally, with a nonparity or non-ECC memory system, tracing the problem is difficult, which is not the case with parity or ECC. These techniques at least isolate a memory source as the culprit, thus reducing both the time and cost of resolving the problem.

Parity Checking

One standard IBM set for the industry is that the memory chips in a bank of nine each handle 1 bit of data: 8 bits per character plus 1 extra bit called the *parity bit*. The parity bit enables memory-control circuitry to keep tabs on the other 8 bits—a built-in cross-check for the integrity of each byte in the system. If the circuitry detects an error, the computer stops and displays a message informing you of the malfunction. If you are running a GUI operating system, such as Windows or OS/2, a parity error generally manifests itself as a locked system. When you reboot, the BIOS should detect the error and display the appropriate error message.

SIMMs and DIMMs are available both with and without parity bits. Originally, all PC systems used parity-checked memory to ensure accuracy. Starting in 1994, a disturbing trend developed in the PC-compatible marketplace. Most vendors began shipping systems without parity checking or any other means of detecting or correcting errors! These systems can use cheaper nonparity SIMMs, which saves about 10%–15% on memory costs for a system. Parity memory results in increased initial system cost, primarily because of the additional memory bits involved. Parity can't correct system errors, but because parity can detect errors, it can make the user aware of memory errors when they happen. This has two basic benefits:

- Parity guards against the consequences of faulty calculations based on incorrect data.
- Parity pinpoints the source of errors, which helps with problem resolution, thus improving system serviceability.

PC systems can easily be designed to function using either parity or nonparity memory. The cost of implementing parity as an option on a motherboard is virtually nothing; the only cost is in actually purchasing the parity SIMMs or DIMMs, which are about 10%–15% more expensive than nonparity versions. This enables a system manufacturer to offer its system purchasers the choice of parity if the purchasers feel the additional cost is justified for their particular applications.

Unfortunately, several of the big names began selling systems without parity to reduce their prices, and they did not make it well known that the lower cost meant parity memory was no longer included as standard. This began happening mostly in 1994 and 1995, and has continued until recently, with few people understanding the full implications. After one or two major vendors did this, most of the others were forced to follow to remain price-competitive.

Because nobody wanted to announce this information, it remained sort of a dirty little secret within the industry. Originally, when this happened, you could still specify parity memory when you ordered a system, even though the default configurations no longer included it. There was a 10%–15% surcharge on the memory, but those who wanted reliable, trustworthy systems could at least get them, provided they knew to ask, of course. Then a major bomb hit the industry, in the form of the Intel Triton 430FX Pentium chipset, which was the first major chipset on the market that did not support parity checking at all! It also became the most popular chipset of its time and was found in practically all Pentium motherboards sold in the 1995 timeframe. This set a disturbing trend for the next few years. All but one of Intel's Pentium processor chipsets after the 430FX did not support parity-checked memory; the only one that did was the 430HX Triton II.

Since then, Intel and other chipset manufacturers have put support for parity and ECC memory in most of their chipsets (especially so in their higher-end models). The low-end chipsets, however, typically do lack support for either parity or ECC. If more reliability is important to you, make sure the systems you purchase have this support.

Let's look at how parity checking works, and then examine in more detail the successor to parity checking, called ECC, which can not only detect but correct memory errors on-the-fly.

IBM originally established the odd parity standard for error checking. The following explanation might help you understand what is meant by odd parity. As the 8 individual bits in a byte are stored in memory, a parity generator/checker, which is either part of the CPU or located in a special chip on the motherboard, evaluates the data bits by adding up the number of 1s in the byte. If an even number of 1s is found, the parity generator/checker then creates a 1 and stores it as the ninth bit (parity bit) in the parity memory chip. That makes the sum for all 9 bits (including the parity bit) an odd number. If the original sum of the 8 data bits is an odd number, the parity bit created would be a 0, keeping the sum for all 9 bits an odd number. The basic rule is that the value of the parity bit is always chosen so that the sum of all 9 bits (8 data bits plus 1 parity bit) is stored as an odd number. If the system used even parity, the example would be the same except the parity bit would be created to ensure an even sum. It doesn't matter whether even or odd parity is used; the system uses one or the other, and it is completely transparent to the memory chips involved. Remember that the 8 data bits in a byte are numbered 0 1 2 3 4 5 6 7. The following examples might make it easier to understand:

```
Data bit number:     0 1 2 3 4 5 6 7     Parity bit
Data bit value:      1 0 1 1 0 0 1 1     0
```

In this example, because the total number of data bits with a value of 1 is an odd number (5), the parity bit must have a value of 0 to ensure an odd sum for all 9 bits.

Here is another example:

```
Data bit number:     0 1 2 3 4 5 6 7     Parity bit
Data bit value:      1 1 1 1 0 0 1 1     1
```

In this example, because the total number of data bits with a value of 1 is an even number (6), the parity bit must have a value of 1 to create an odd sum for all 9 bits.

When the system reads memory back from storage, it checks the parity information. If a (9-bit) byte has an even number of bits with a parity bit value of 1, that byte must have an error. The system can't tell which bit has changed or whether only a single bit has changed. If 3 bits changed, for example, the byte still flags a parity-check error; if 2 bits changed, however, the bad byte could pass unnoticed. Because multiple bit errors (in a single byte) are rare, this scheme gives you a reasonable and inexpensive ongoing indication that memory is good or bad.

The following examples show parity-check messages for three types of older systems:

```
For the IBM PC:                       PARITY CHECK x
For the IBM XT:                       PARITY CHECK x     yyyyy (z)
For the IBM AT and late model XT:     PARITY CHECK x     yyyyy
```

Where `x` is `1` or `2`:

`1` = Error occurred on the motherboard

`2` = Error occurred in an expansion slot

In this example, *yyyyy* represents a number from 00000 through FFFFF that indicates, in hexadecimal notation, the byte in which the error has occurred.

Where `(z)` is `(S)` or `(E)`:

`(S)` = Parity error occurred in the system unit

`(E)` = Parity error occurred in an optional expansion chassis

Note

An expansion chassis was an option IBM sold for the original PC and XT systems to add more expansion slots. This unit consisted of a backplane motherboard with eight slots; one slot contained a special extender/receiver card cabled to a similar extender/receiver card placed in the main system. Because of the extender/receiver cards in the main system and the expansion chassis, the net gain was six slots. Although the IBM version has long since been discontinued, other companies have since produced 8-bit and 16-bit ISA expansion chassis, enabling more ISA slots to be added to a system.

When a parity-check error is detected, the motherboard parity-checking circuits generate a *nonmaskable interrupt (NMI)*, which halts processing and diverts the system's attention to the error. The NMI causes a routine in the ROM to be executed. The routine clears the screen and then displays a message in the screen's upper-left corner. The message differs depending on the type of computer system. On some older IBM systems, the ROM parity-check routine halts the CPU. In such a case, the system locks up, and you must perform a hardware reset or a power-off/power-on cycle to restart the system. Unfortunately, all unsaved work is lost in the process.

Most systems do not halt the CPU when a parity error is detected; instead, they offer you the choice of rebooting the system or continuing as though nothing happened. Additionally, these systems might display the parity error message in a different format from IBM, although the information presented is basically the same. For example, most systems with a Phoenix BIOS display one of these messages:

```
Memory parity interrupt at xxxx:xxxx
Type (S)hut off NMI, Type (R)eboot, other keys to continue
```

or

```
I/O card parity interrupt at xxxx:xxxx
Type (S)hut off NMI, Type (R)eboot, other keys to continue
```

The first of these two messages indicates a motherboard parity error (Parity Check 1), and the second indicates an expansion-slot parity error (Parity Check 2). Notice that the address given in the form *xxxx:xxxx* for the memory error is in a segment:offset form rather than a straight linear address, such as with IBM's error messages. The segment:offset address form still gives you the location of the error to a resolution of a single byte.

You have three ways to proceed after viewing this error message:

- You can press S, which shuts off parity checking and resumes system operation at the point where the parity check first occurred.
- You can press R to force the system to reboot, losing any unsaved work.
- You can press any other key to cause the system to resume operation with parity checking still enabled.

If the problem occurs, it is likely to cause another parity-check interruption. It's usually prudent to press S, which disables the parity checking so you can then save your work. In this case, it's best to save your work to a floppy disk to prevent the possible corruption of the hard disk. You should also avoid overwriting any previous (still good) versions of whatever file you are saving because you could be saving a bad file caused by the memory corruption. Because parity checking is now disabled, your save operations will not be interrupted. Then, you should power the system off, restart it, and run whatever memory diagnostics software you have to try to track down the error. In some cases, the POST finds the error on the next restart, but you usually need to run a more sophisticated diagnostics program—perhaps in a continuous mode—to locate the error.

Systems with an AMI BIOS display the parity error messages in the following forms:

```
ON BOARD PARITY ERROR ADDR (HEX) = (xxxxx)
```

or

```
OFF BOARD PARITY ERROR ADDR (HEX) = (xxxxx)
```

These messages indicate that an error in memory has occurred during the POST, and the failure is located at the address indicated. The first one indicates that the error occurred on the motherboard, and the second message indicates an error in an expansion slot adapter card. The AMI BIOS can also display memory errors in the following manners:

```
Memory Parity Error at xxxxx
```

or

```
I/O Card Parity Error at xxxxx
```

These messages indicate that an error in memory has occurred at the indicated address during normal operation. The first one indicates a motherboard memory error, and the second indicates an expansion slot adapter memory error.

Although many systems enable you to continue processing after a parity error and even allow disabling further parity checking, continuing to use your system after a parity error is detected can be dangerous. The idea behind letting you continue using either method is to give you time to save any unsaved work before you diagnose and service the computer, but be careful how you do this.

Note that these messages can vary depending not only on the ROM BIOS but also on your operating system. Protected mode operating systems, such as most versions of Windows, trap these errors and run their own handler program that displays a message different from what the ROM would have displayed. The message might be associated with a blue screen or might be a trap error, but it usually indicates that it is memory or parity related. For example, Windows 98 displays a message indicating `Memory parity error detected. System halted.` when such an error has occurred.

Caution

When you are notified of a memory parity error, remember the parity check is telling you that memory has been corrupted. Do you want to save potentially corrupted data over the good file from the last time you saved? Definitely not! Be sure you save your work with a different filename. In addition, after a parity error, save only to a floppy disk if possible and avoid writing to the hard disk; there is a slight chance that the hard drive could become corrupted if you save the contents of corrupted memory.

After saving your work, determine the cause of the parity error and repair the system. You might be tempted to use an option to shut off further parity checking and simply continue using the system as though nothing were wrong. Doing so is like unscrewing the oil pressure warning indicator bulb on a car with an oil leak so the oil pressure light won't bother you anymore!

A few years ago, when memory was more expensive, a few companies were marketing SIMMs with bogus parity chips. Instead of actually having the extra memory chips needed to store the parity bits, these "logic parity" or parity "emulation" SIMMs used an onboard parity generator chip. This chip ignored any parity the system was trying to store on the SIMM, but when data was retrieved, it always ensured that the correct parity was returned, thus making the system believe all was well even though there might be a problem.

These bogus parity modules were used because memory was much more expensive, and a company could offer a "parity" SIMM for only a few dollars more with the fake chip. Unfortunately, identifying them can be difficult. The bogus parity generator doesn't look like a memory chip, and has different markings from the other memory chips on the SIMM. Most of them had a "GSM" logo, which indicated the original manufacturer of the parity logic device, not necessarily the SIMM itself.

One way to positively identify these bogus fake parity SIMMs is by using a hardware SIMM test machine, such as those by Darkhorse Systems or Aristo. Of course, I don't recommend using bogus parity SIMMs. Fortunately, the problem has mostly subsided because honest-to-gosh memory is much cheaper these days.

Error Correcting Code

ECC goes a big step beyond simple parity-error detection. Instead of just detecting an error, ECC allows a single bit error to be corrected, which means the system can continue without interruption and without corrupting data. ECC, as implemented in most PCs, can only detect, not correct, double-bit errors. Because studies have indicated that approximately 98% of memory errors are the single-bit variety, the most commonly used type of ECC is one in which the attendant memory controller detects and corrects single-bit errors in an accessed data word (double-bit errors can be detected, but not corrected). This type of ECC is known as *single-bit error-correction double-bit error detection (SEC-DED)* and requires an additional 7 check bits over 32 bits in a 4-byte system and an additional 8 check bits over 64 bits in an 8-byte system. ECC in a 4-byte (32-bit, such as a 486) system obviously costs more than non-parity or parity, but in an 8-byte wide bus (64-bit, such as Pentium/Athlon) system, ECC and parity costs are equal because the same number of extra bits (8) is required for either parity or ECC. Because of this, you can purchase parity SIMMs (36-bit), DIMMs (72-bit), or RIMMs

(18-bit) for 32-bit systems and use them in an ECC mode if the chipset supports ECC functionality. If the system uses SIMMs, two 36-bit (parity) SIMMs are added for each bank (for a total of 72-bits), and ECC is done at the bank level. If the system uses DIMMs, a single parity/ECC 72-bit DIMM is used as a bank and provides the additional bits. RIMMs are installed in singles or pairs, depending on the chipset and motherboard. They must be 18-bit versions if parity/ECC is desired.

ECC entails the memory controller calculating the check bits on a memory-write operation, performing a compare between the read and calculated check-bits on a read operation, and, if necessary, correcting bad bits. The additional ECC logic in the memory controller is not very significant in this age of inexpensive, high-performance VLSI logic, but ECC actually affects memory performance on writes. This is because the operation must be timed to wait for the calculation of check bits and, when the system waits for corrected data, reads. On a partial-word write, the entire word must first be read, the affected byte(s) rewritten, and then new check bits calculated. This turns partial-word write operations into slower read-modify writes. Fortunately, this performance hit is very small, on the order of a few percent at maximum, so the tradeoff for increased reliability is a good one.

Most memory errors are of a single-bit nature, which can be corrected by ECC. Incorporating this fault-tolerant technique provides high system reliability and attendant availability. An ECC-based system is a good choice for servers, workstations, or mission-critical applications in which the cost of a potential memory error outweighs the additional memory and system cost to correct it, along with ensuring that it does not detract from system reliability. If you value your data and use your system for important (to you) tasks, you'll want ECC memory. No self-respecting manager would build or run a network server, even a lower-end one, without ECC memory.

By designing a system that allows the user to make the choice of ECC, parity, or nonparity, users can choose the level of fault tolerance desired, as well as how much they want to gamble with their data.

Installing RAM Upgrades

Adding memory to a system is one of the most useful upgrades you can perform, and also one of the least expensive—especially when you consider the increased capabilities of Windows 9x, Windows NT, Windows 2000, and OS/2 when you give them access to more memory. In some cases, doubling the memory can practically double the speed of a computer.

The following sections discuss adding memory, including selecting memory chips, installing memory chips, and testing the installation.

Upgrade Options and Strategies

Adding memory can be an inexpensive solution; at this writing, the cost of memory has fallen to about $1 per megabyte or less. A small dose can give your computer's performance a big boost.

How do you add memory to your PC? You have two options, listed in order of convenience and cost:

- Adding memory in vacant slots on your motherboard
- Replacing your current motherboard's memory with higher-capacity memory

If you decide to upgrade to a more powerful computer system or motherboard, you normally can't salvage the memory from your previous system. Most of the time it is best to plan on equipping a new board with the optimum type of memory that it supports.

Be sure to carefully weigh your future needs for computing speed and a multitasking operating system (OS/2, Windows 9x, Windows NT, Windows 2000, or Linux, for example) against the amount of money you spend to upgrade current equipment.

Before you add RAM to a system (or replace defective RAM chips), you must determine the memory chips required for your system. Your system documentation has this information.

If you need to replace a defective memory module and do not have the system documentation, you can determine the correct module for your system by inspecting the ones that are already installed. Each module has markings that indicate the module's capacity and speed. RAM capacity and speed are discussed in detail earlier in this chapter.

If you do not have the documentation for your system and the manufacturer does not offer technical support, open your system case and carefully write down the markings that appear on your memory chips. Then contact a local computer store or module vendor, such as Kingston, Micron (Crucial), PNY, or others, for help in determining the proper RAM chips for your system. Adding the wrong modules to a system can make it as unreliable as leaving a defective module installed and trying to use the system in that condition.

Note

Before upgrading an older Pentium (P5 class) system beyond 64MB of RAM, be sure that your chipset supports caching more than 64MB. Adding RAM beyond the amount supported by your L2 cache slows performance rather than increases it. See the section "Cache Memory: SRAM," earlier in this chapter, and the discussion of chipsets in Chapter 4 for a more complete explanation of this common system limitation. This limitation was mostly with Pentium (P5) class chipsets. Pentium II and later processors, including the AMD Athlon and Duron, have the L2 cache controller integrated in the processor (not the chipset), which supports caching up to 1GB, or 4GB on most newer models.

Selecting and Installing Memory

If you are upgrading a motherboard by adding memory, follow the manufacturer's guidelines on which memory chips or modules to buy. As you learned earlier, memory comes in various form factors, including SIMMs, DIMMs, and RIMMs.

No matter which type of memory modules you have, the chips are installed in memory banks. A *memory bank* is a collection of memory chips that make up a complete row of memory. Your processor reads each row of memory in one pass. A memory bank does not work unless the entire row is filled with memory chips. (Banks are discussed in more detail earlier in this chapter in the section "Memory Banks.")

Installing extra memory on your motherboard is an easy way to add memory to your computer. Most systems have at least one vacant memory bank where you can install extra memory at a later time and speed up your computer.

Replacing Modules with Higher-Capacity Versions

If all the memory module slots on your motherboard are occupied, your best option is to remove an existing bank of memory and replace it with higher-capacity modules. For example, if you have a motherboard that supports two DIMM modules (each representing one bank on a processor with a 64-bit data bus), you could remove one of them and replace it with a higher-capacity version. For example, if you have two 64MB modules giving a total of 128MB, you could remove one of the 64MB modules and replace it with a 128MB unit, in which case you'd then have a total of 192MB of RAM.

However, just because higher-capacity modules are available that are the correct pin count to plug into your motherboard, don't automatically assume the higher-capacity memory will work. Your system's chipset and BIOS set limits on the capacity of the memory you can use. Check your system or motherboard documentation to see which size modules work with it before purchasing the new RAM. You should make sure you have the latest BIOS when installing new memory.

Installing Memory

This section discusses installing memory—specifically, new SIMM or DIMM modules. It also covers the problems you are most likely to encounter and how to avoid them. You also get information on configuring your system to use new memory.

When you install or remove memory, you are most likely to encounter the following problems:

- Electrostatic discharge
- Improperly seated modules
- Incorrect memory configuration settings in the BIOS Setup

To prevent electrostatic discharge (ESD) when you install sensitive memory chips or boards, do not wear synthetic-fiber clothing or leather-soled shoes. Remove any static charge you are carrying by touching the system chassis before you begin, or better yet, wear a good commercial grounding strap on your wrist. You can order one from an electronics parts store or mail-order house. A grounding strap consists of a conductive wristband grounded at the other end by a wire clipped to the system chassis. Leave the system unit plugged in—but turned off—to keep it grounded.

Caution

Be sure to use a properly designed commercial grounding strap; do not make one yourself. Commercial units have a one-meg ohm resistor that serves as protection if you accidentally touch live power. The resistor ensures that you do not become the path of least resistance to the ground and therefore become electrocuted. An improperly designed strap can cause the power to conduct through you to the ground, possibly killing you.

Each memory chip or module must be installed in a specific orientation. Interference fit notches and tangs are designed to prevent improper installation of the module into the socket. As long as you are observant and don't try to force anything, the proper orientation should be fairly easy to figure out. As you insert the module, be sure the notches align with the appropriate tangs on the socket.

I would hope it goes without saying, but before installing memory, be sure the system power is off! You should make sure the system is unplugged just to be sure. If you were to install memory while the power was on (even if the system was in a sleep mode), you would probably fry not only the memory but possibly the entire motherboard as well.

You remove SIMMs and DIMMs by releasing the locking tabs and either pulling or rolling them out of their sockets. The installation is exactly the opposite.

After adding the memory and putting the system back together, you might have to run the BIOS Setup and resave with the new amount of memory being reported. Most newer systems automatically detect the new amount of memory and reconfigure the BIOS Setup settings for you. Most newer systems also don't require setting any jumpers or switches on the motherboard to configure them for your new memory.

Note

Information on installing memory on older memory expansion cards can be found in Chapter 7 of *Upgrading and Repairing PCs, 6th Edition*, which is included in its entirety on the CD accompanying this book.

After configuring your system to work properly with the additional memory, you might want to run a memory-diagnostics program to ensure that the new memory works properly. Some are run automatically for you. At least two and sometimes three memory-diagnostic programs are available for all systems. In order of accuracy, these programs are as follows:

- POST (power on self test)
- Disk-based advanced diagnostics software

The POST is used every time you power up the system.

Many additional diagnostics programs are available from aftermarket utility software companies. More information on aftermarket testing facilities can be found in Chapter 24.

Installing SIMMs

SIMM memory is oriented by a notch on one side of the module that is not present on the other side, as shown in Figure 6.14. The socket has a protrusion that must fit into this notched area on one side of the module. This protrusion makes installing a SIMM backward impossible unless you break the connector or the module. Figure 6.15 details the notch and the locking clip.

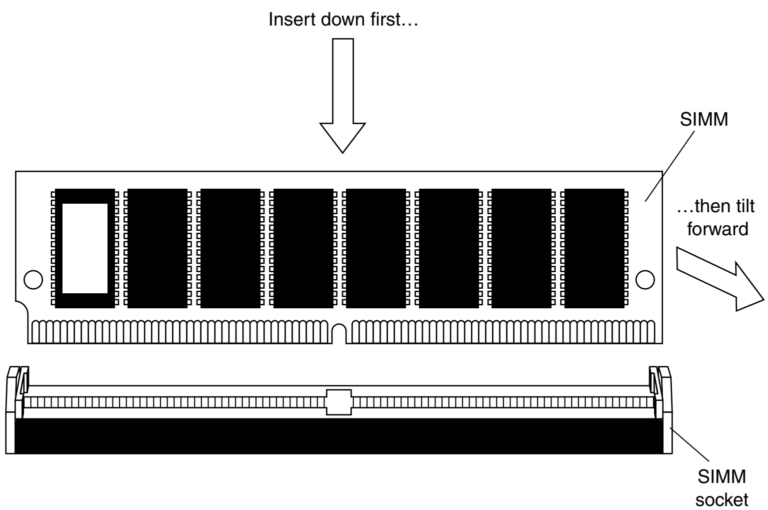

Figure 6.14 The notch on this SIMM is shown on the left side. Insert the SIMM at a 45° angle and then tilt it forward until the locking clips snap into place.

Installing DIMMs and RIMMs

Similarly, DIMMs and RIMMs are keyed by notches along the bottom connector edge that are offset from the center so they can be inserted in only one direction, as shown in Figure 6.16.

The DIMM/RIMM ejector tab locks into place in the notch on the side of the DIMM when it is fully inserted. Some DIMM sockets have ejector tabs on both ends. Take care not to force the module into the socket. If the module does not slip easily into the slot and then snap into place, there is a good chance the module is not oriented or aligned correctly. Forcing the module could break the module or the socket. If the retaining clips on the socket break, the memory isn't held firmly in place, and you likely will get random memory errors because the module can't make consistent electrical contact if it is loose.

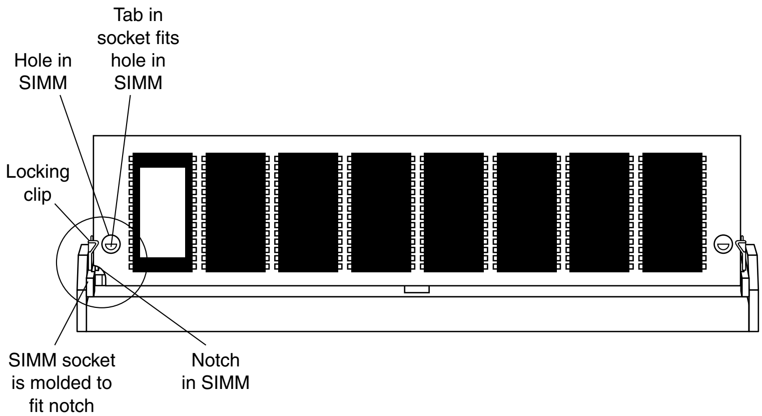

Figure 6.15 This figure shows the SIMM inserted in the socket with the notch aligned, the locking clip locked, and the hole in the SIMM aligned with the tab in the socket.

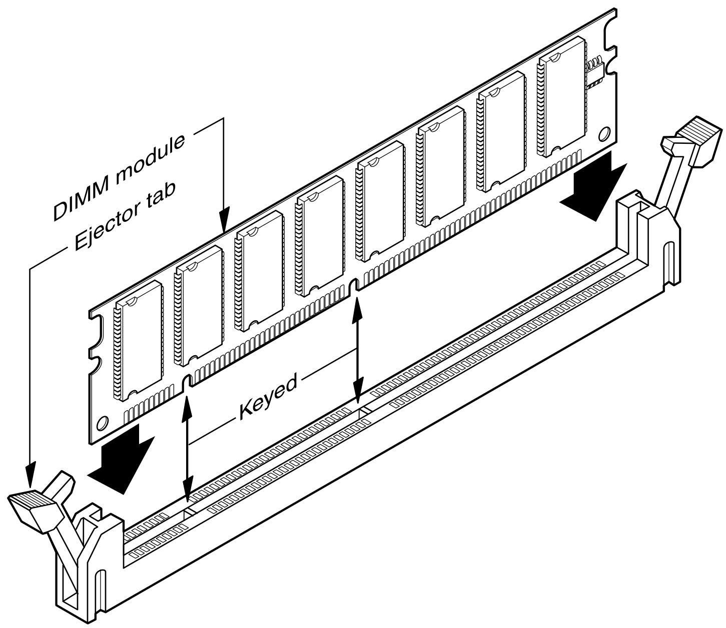

Figure 6.16 DIMM keys match the protrusions in the DIMM sockets. DDR DIMM and RIMM keys are similar but not exactly the same.

Installing RIMMs

RIMMs install in exactly the same manner as DIMMs, although in different sockets. The ejector tabs on the sides are similar, and they go in at a straight 90° angle just like DIMMs. The key notches on the RIMM prevent backwards installation and aid alignment when inserting them.

You'll also need to fill any empty RIMM sockets with a continuity module. Refer to Figure 6.11 for details on adding this module.

Troubleshooting Memory

Memory problems can be difficult to troubleshoot. For one thing, computer memory is still mysterious to people because it is a kind of "virtual" thing that can be hard to grasp. The other difficulty is that memory problems can be intermittent and often look like problems with other areas of the system, even software. This section shows simple troubleshooting steps you can perform if you suspect you are having a memory problem.

To troubleshoot memory, you first need some memory-diagnostics testing programs. You already have several, and might not know it! Every motherboard BIOS has a memory diagnostic in the POST that runs when you first turn on the system. In most cases, you also received a memory diagnostic on a utility disk that came with your system. Finally, a commercial program called Check-It is included on the CD-ROM with this book. Many other commercial diagnostics programs are on the market, and almost all of them include memory tests.

When the POST runs, it not only tests memory, but also counts it. The count is compared to the amount counted the last time BIOS Setup was run; if it is different, an error message is issued. As the POST runs, it writes a pattern of data to all the memory locations in the system and reads that pattern back to verify that the memory works. If any failure is detected, you see or hear a message. Audio messages (beeping) are used for critical or "fatal" errors that occur in areas important for the system's operation. If the system can access enough memory to at least allow video to function, you see error messages instead of hearing beep codes.

See the CD accompanying this book for detailed listings of the BIOS beep and other error codes, which are specific to the type of BIOS you have. These BIOS codes are found in the Technical Reference section of the CD in printable PDF format for your convenience. For example, most Intel motherboards use the Phoenix BIOS. Several beep codes are used in that BIOS to indicate fatal memory errors.

If your system makes it through the POST with no memory error indications, there might not be a hardware memory problem, or the POST might not be able to detect the problem. Intermittent memory errors are often not detected during the POST, and other subtle hardware defects can be hard for the POST to catch. The POST is designed to run quickly, so the testing is not nearly as thorough as it could be. That is why you often have to boot from a DOS or diagnostic disk and run a true hardware diagnostic to do more extensive memory testing. These types of tests can be run continuously, and left running for days if necessary to hunt down an elusive intermittent defect.

Still, even these programs do only pass/fail type testing; that is, all they can do is write patterns to memory and read them back. They can't determine how close the memory is to failing—only that it worked or not. For the highest level of testing, the best thing to have is a dedicated memory test machine, usually called a *SIMM/DIMM tester*. These devices enable you to insert a module and test it thoroughly at a variety of speeds, voltages, and timings to let you know for certain whether the memory is good or bad. I have defective SIMMs, for example, that work in some systems (slower ones) but not others. What I mean is that the *same* memory test program fails the SIMM in one machine but passes it in another. In the SIMM tester, it is always identified as bad right down to the individual bit, and it even tells me the actual speed of the device, not just its rating. Several companies that offer SIMM/DIMM testers are included in the Vendor List, including Darkhorse Systems and Aristo. They can be expensive, but for a professional in the PC repair business, using one of these SIMM/DIMM testers is the only way to go.

After your operating system is running, memory errors can still occur, typically identified by error messages you might receive. These are the most common:

- *Parity errors*. Indicates that the parity-checking circuitry on the motherboard has detected a change in memory since the data was originally stored. (See the "Parity Checking" section earlier in this chapter.)
- *General or global protection faults*. A general-purpose error indicating that a program has been corrupted in memory, usually resulting in immediate termination of the application. This can also be caused by buggy or faulty programs.
- *Fatal exception errors*. Error codes returned by a program when an illegal instruction has been encountered, invalid data or code has been accessed, or the privilege level of an operation is invalid.
- *Divide error.* A general-purpose error indicating that a division by 0 was attempted or the result of an operation does not fit in the destination register.

If you are encountering these errors, they could be caused by defective or improperly configured memory, but they can also be caused by software bugs (especially drivers), bad power supplies, static discharges, close proximity radio transmitters, timing problems, and more.

If you suspect the problems are caused by memory, there are ways to test the memory to determine whether that is the problem. Most of this testing involves running one or more memory test programs.

I am amazed that most people make a critical mistake when they run memory test software. The biggest problem I see is that people run memory tests with the system caches enabled. This effectively invalidates memory testing because most systems have what is called a *write-back cache*. This means that data written to main memory is first written to the cache. Because a memory test program first writes data and then immediately reads it back, the data is read back from the cache, not the main memory. It makes the memory test program run very quickly, but all you tested was the cache. The bottom line is that if you test memory with the cache enabled, you aren't really writing to the SIMM/DIMMs, but only to the cache. Before you run any memory test programs, be sure your cache is disabled. The system will run very slowly when you do this, and the memory test will take much longer to complete, but you will be testing your actual RAM, not the cache.

The following steps enable you to effectively test and troubleshoot your system RAM. Figure 6.17 provides a boiled-down procedure to help you step through the process quickly.

First, let's cover the memory testing and troubleshooting procedures.

1. Power up the system and observe the POST. If the POST completes with no errors, basic memory functionality has been tested. If errors are encountered, go to the defect isolation procedures.
2. Restart the system, and enter your BIOS (or CMOS) Setup. In most systems, this is done by pressing the F2 key during the POST but before the boot process begins. Once in BIOS Setup, verify that the memory count is equal to the amount that has been installed. If the count does not match what has been installed, go to the defect isolation procedures.
3. Find the BIOS Setup options for cache, and set all cache options to disabled. Save the settings and reboot to a DOS-formatted system disk (floppy) containing the diagnostics program of your choice. If your system came with a diagnostics disk, you can use that, or you can use one of the many commercial PC diagnostics programs on the market, such as PC-Technician by Windsor Technologies (which comes in self-booting form), the Norton Utilities by Symantec, or others.

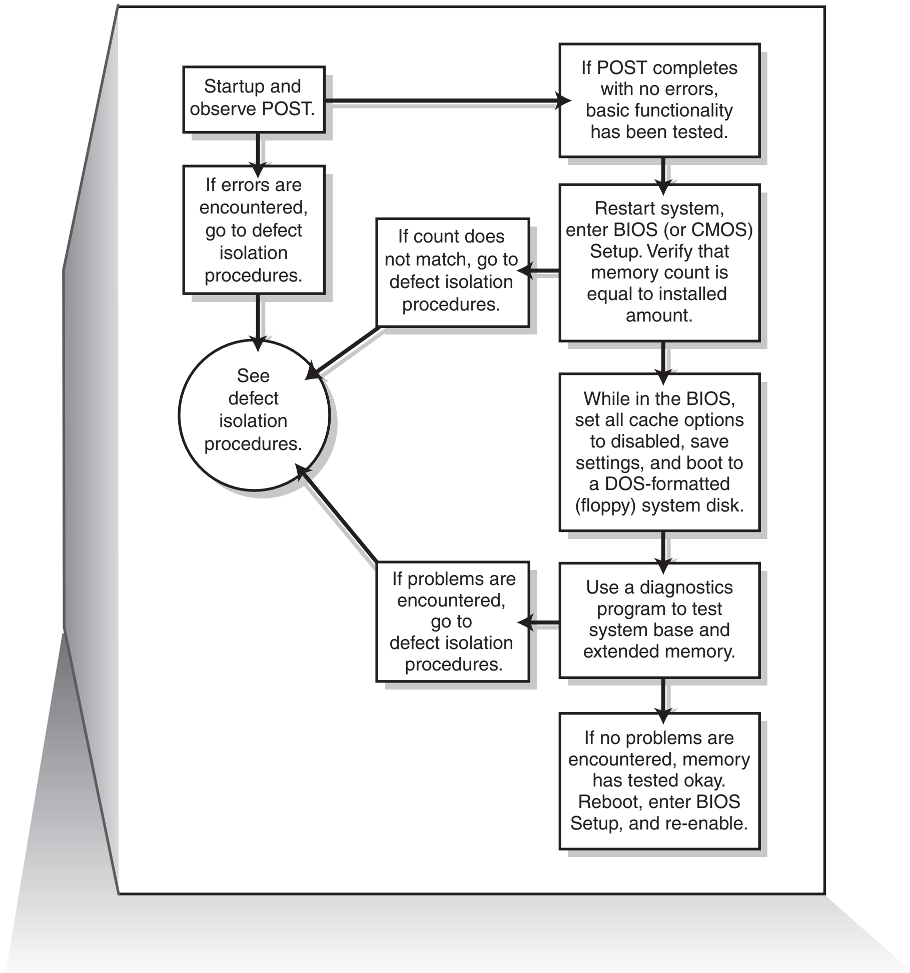

Figure 6.17 Testing and troubleshooting memory.

4. Follow the instructions that came with your diagnostic program to have it test the system base and extended memory. Most programs have a mode that enables them to loop the test—that is, to run it continuously, which is great for finding intermittent problems. If the program encounters a memory error, proceed to the defect isolation procedures.
5. If no errors are encountered in the POST or in the more comprehensive memory diagnostic, your memory has tested okay in hardware. Be sure at this point to reboot the system, enter the BIOS Setup, and reenable the cache. The system will run very slowly until the cache is turned back on.
6. If you are having memory problems yet the memory still tests okay, you might have a problem undetectable by simple pass/fail testing, or your problems could be caused by software or one of many other defects or problems in your system. You might want to bring the memory to a SIMM/DIMM tester for a more accurate analysis. Most PC repair shops have such a tester. I would also check the software (especially drivers, which might need updating), power supply, and system environment for problems such as static, radio transmitters, and so forth.

Memory Defect Isolation Procedures

To use these steps, I am assuming you have identified an actual memory problem that is being reported by the POST or disk-based memory diagnostics. If this is the case, see the following steps and Figure 6.18 for the steps to identify or isolate which SIMM or DIMM in the system is causing the problem.

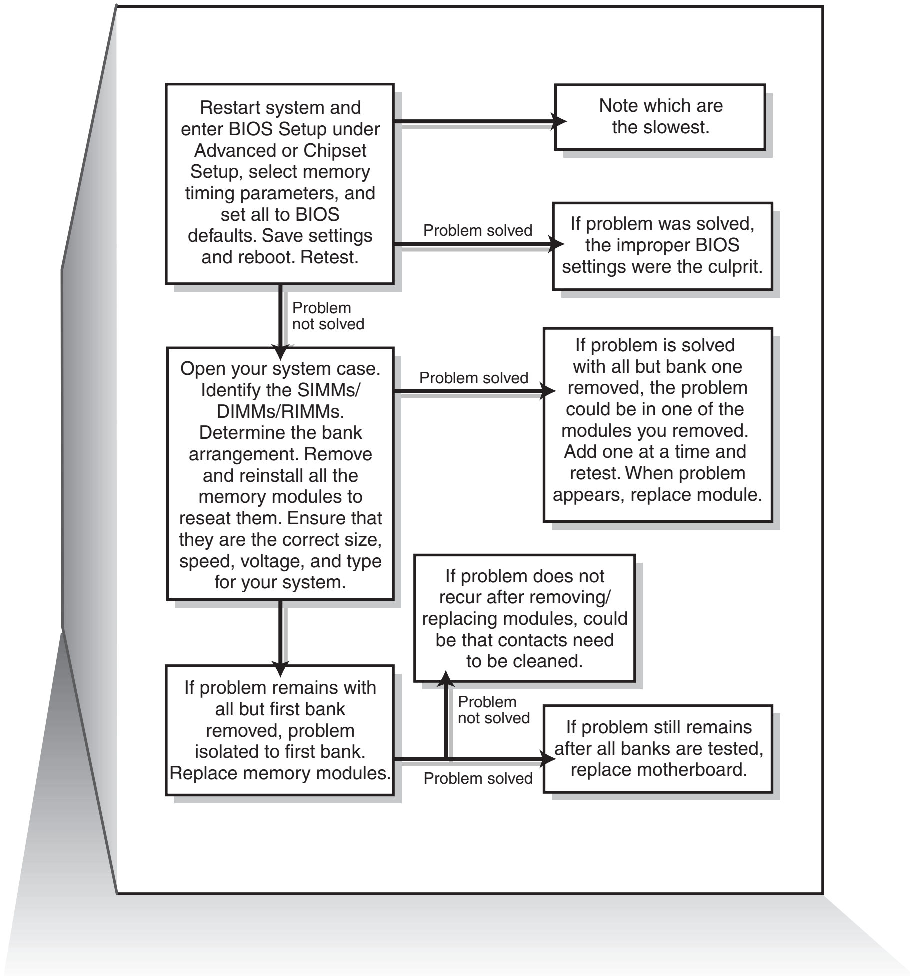

Figure 6.18 Follow these steps if you are still encountering memory errors after completing the steps in Figure 6.17.

1. Restart the system and enter the BIOS Setup. Under a menu usually called Advanced or Chipset Setup might be memory timing parameters. Select BIOS or Setup defaults, which are usually the slowest settings. Save the settings, reboot, and retest using the testing and troubleshooting procedures listed earlier. If the problem has been solved, improper BIOS settings were the problem. If the problem remains, you likely do have defective memory, so continue to the next step.

2. Open the system for physical access to the SIMM/DIMMs on the motherboard. Identify the bank arrangement in the system. For example, Pentium systems use 64-bit banks, which means two 72-pin SIMMs or one 168-pin DIMM per bank. Using the manual or the legend silk-screened on the motherboard, identify which SIMMs or DIMM correspond to which bank. Most Pentium boards that use SIMMs have four, six, or eight total SIMMs installed in two, three, or four banks. Most boards using DIMMs have two, three, or four total DIMMs, each of which represents a single bank.
3. Remove all the memory except the first bank, and retest using the troubleshooting and testing procedures listed earlier. If the problem remains with all but the first bank removed, the problem has been isolated to the first bank, which must be replaced.
4. Replace the memory in the first bank, preferably with known good spare modules, but you can also swap in others that you have removed and retest. If the problem *still* remains after testing all the memory banks (and finding them all to be working properly), it is likely the motherboard itself is bad (probably one of the memory sockets). Replace the motherboard and retest.
5. At this point, the first (or previous) bank has tested good, so the problem must be in the remaining modules that have been temporarily removed. Install the next bank of memory and retest. If the problem resurfaces now, the memory in that bank is defective. Continue testing each bank until you find the defective module.
6. Repeat the preceding step until all remaining banks of memory are installed and have been tested. If the problem has not resurfaced after removing and reinstalling all the memory, the problem was likely intermittent or caused by poor conduction on the memory contacts. Often simply removing and replacing memory can resolve problems because of the self-cleaning action between the SIMM/DIMM and the socket during removal and reinstallation.

The System Logical Memory Layout

The original PC had a total of 1MB of addressable memory, and the top 384KB of that was reserved for use by the system. Placing this reserved space at the top (between 640KB and 1024KB instead of at the bottom, between 0KB and 640KB) led to what is often called the *conventional memory barrier*. The constant pressures on system and peripheral manufacturers to maintain compatibility by never breaking from the original memory scheme of the first PC has resulted in a system memory structure that is (to put it kindly) a mess. Almost two decades after the first PC was introduced, even the newest Pentium 4–based systems are limited in many important ways by the memory map of the first PCs.

What we end up with is a PC with a split personality. There are two primary modes of operation that are very different from each other. The original PC used an Intel 8088 processor that could run only 16-bit instructions or code, which ran in what was called the real mode of the processor. These early processors had only enough address lines to access up to 1MB of memory, and the last 384KB of that was reserved for use by the video card as video RAM, other adapters (for on-card ROM BIOS), and finally the motherboard ROM BIOS.

The 286 processor brought more address lines, enough to allow up to 16MB of RAM to be used, and a new mode called *protected mode* that you had to be in to use it. Unfortunately, all the operating systems software at the time was designed to run only within the first 1MB, so extender programs were added and other tricks performed to eventually allow DOS and Windows 3.x access up to the first 16MB. One area of confusion was that RAM was now noncontiguous; that is, the operating system could use the first 640KB and the last 15MB, but not the 384KB of system reserved area that sat in between.

When the first 32-bit processor was released by Intel in 1985 (the 386DX), the memory architecture of the system changed dramatically. There were now enough address lines for the processor to use 4GB of memory, but this was accessible only in a new 32-bit *protected mode* in which only 32-bit instructions or code could run. This mode was designed for newer, more advanced operating systems, such as Windows 9x, NT, 2000, OS/2, Linux, Unix, and so forth. With the 386 came a whole new memory architecture in which this new 32-bit software could run. Unfortunately, it took 10 years for the mainstream user to upgrade to 32-bit operating systems and applications, which shows how stubborn we are! From a software instruction perspective, all the 32-bit processors since the 386 are really just faster versions of the same. Other than the more recent additions of MMX and SSE (or AMD's 3DNow) instructions to the processor, for all intents and purposes, a Pentium 4 or Athlon is just a "turbo" 386.

The real problem now is that the 32-bit processors have two distinctly different modes, with different memory architectures in each. For backward compatibility, you could still run the 32-bit processors in real mode, but only 16-bit software could run in that mode, and such software could access only the first 1MB or 16MB, depending on how it was written. For example, 16-bit drivers could load into and access only the first 1MB. Also, it is worth noting that the system ROM BIOS, including the POST, BIOS configuration, boot code, and all the internal drivers, is virtually all 16-bit software. This is because all Intel-compatible PC processors begin operation in 16-bit real mode when they are powered on. When a 32-bit operating system loads, it is that operating system code that instructs the processor to switch into 32-bit protected mode.

When an operating system such as Windows is loaded, the processor is switched into 32-bit protected mode early in the loading sequence. Then, 32-bit drivers for all the hardware can be loaded, and then the rest of the operating system can load. In 32-bit protected mode, the operating systems and applications can access all the memory in the system, up to the maximum limit of the processor (64TB for most of the Pentium II and later chips).

Unfortunately, one problem with protected mode is just that: It is protected. The name comes from the fact that only driver programs are allowed to talk directly to the hardware in this mode; programs loaded by the operating system, such as by clicking an icon in Windows, are not allowed to access memory or other hardware directly. This protection is provided so that a single program can't crash the machine by doing something illegal. You might have seen the error message in Windows indicating this, and that the program will be shut down.

Diagnostics software by nature must talk to the hardware directly. This means that little intensive diagnostics testing can be done while a protected mode operating system such as Windows 9x, NT, 2000, Linux, and so forth is running. For system testing, you usually have to boot from a DOS floppy or interrupt the loading of Windows (press the F8 key when "Starting Windows" appears during the boot process) and select Command Prompt Only, which boots you into DOS. In Windows 9x (but not Me), you can execute a shutdown and select Restart the Computer in MS-DOS Mode. Many of the higher-end hardware diagnostics programs include their own special limited 16-bit operating systems so they can more easily access memory areas even DOS would use.

For example, when you boot from a Windows 9x startup disk, you are running 16-bit DOS, and if you want to access your CD-ROM drive to install Windows, you must load a 16-bit CD-ROM driver program from that disk as well. In this mode, you can do things such as partition and format your hard disk, install Windows, or test the system completely.

The point of all this is that although you might not be running DOS very much these days, at least for system configuration and installation, as well as for high-level hardware diagnostics testing, data recovery, and so forth, you still must boot a 16-bit OS occasionally. When you are in that mode, the system's architecture changes, less memory is accessible, and some of the software you are running (16-bit drivers and most application code) must fight over the first 1MB or even 640KB for space.

The system memory areas discussed in this chapter, including the 384KB at the top of the first megabyte, which is used for video, adapter BIOS, and motherboard BIOS, as well as the remaining extended memory, are all part of the PC hardware design. They exist whether you are running 16-bit or 32-bit software; however, the limitations on their use in 16-bit (real) mode are much more severe. Because most people run 32-bit operating systems, such as Windows 9x, 2000, Linux, and so on, these operating systems automatically manage the use of RAM, meaning you don't have to interact with and manage this memory yourself as you often did with the 16-bit operating systems.

The following sections are intended to give you an understanding of the PC hardware memory layout, which is consistent no matter which operating system you use. The only things that change are how your operating system uses these areas and how they are managed by the OS.

The following sections detail the various types of memory installed on a modern PC. The kinds of memory covered in the following sections include

- Conventional (base) memory
- Upper memory area (UMA)
- High memory area (HMA)
- Extended memory (XMS)
- Expanded memory (obsolete)
- Video RAM memory (part of UMA)
- Adapter ROM and special-purpose RAM (part of UMA)
- Motherboard ROM BIOS (part of UMA)

Figure 6.19 shows the logical address locations for a 16-bit or higher system. If the processor is running in real mode, only the first megabyte is accessible. If the processor is in protected mode, the full 16MB, 4,096MB, or 65,536MB are accessible. Each symbol is equal to 1KB of memory, and each line or segment is 64KB. This map shows the first two megabytes of system memory.

◄◄ See "Processor Modes," p. 67.

Note

To save space, this map stops after the end of the second megabyte. In reality, this map continues to the maximum of addressable memory.

Conventional (Base) Memory

The original PC/XT-type system was designed to use 1MB of RAM. This 1MB of RAM is divided into several sections, some of which have special uses. DOS can read and write to the entire megabyte but can manage the loading of programs only in the portion of RAM space called *conventional memory*, which was 512KB at the time the first PC was introduced. The other 512KB was reserved for use by the system, including the motherboard and adapter boards plugged into the system slots.

After introducing the system, IBM decided that only 384KB was needed for these reserved uses, and the company began marketing PCs with 640KB of user memory. Therefore, 640KB became the standard for memory that can be used by DOS for running programs and often is termed the 640KB memory barrier. The remaining memory after 640KB was reserved for use by the graphics boards, other adapters, and the motherboard ROM BIOS.

```
. = Program-accessible memory (standard RAM)
G = Graphics Mode Video RAM
M = Monochrome Text Mode Video RAM
C = Color Text Mode Video RAM
V = Video ROM BIOS (would be "a" in PS/2)
a = Adapter board ROM and special-purpose RAM (free UMA space)
r = Additional PS/2 Motherboard ROM BIOS (free UMA in non-PS/2 systems)
R = Motherboard ROM BIOS
b = IBM Cassette BASIC ROM (would be "R" in IBM compatibles)
h = High Memory Area (HMA), if HIMEM.SYS is loaded.

```

Figure 6.19 The logical memory map of the first 2MB.

This barrier largely affects 16-bit software, such as DOS and Windows 3.1, and is much less of a factor with 32-bit software and operating systems, such as Windows 9x, NT/2000, and so on.

Upper Memory Area

The term *Upper Memory Area (UMA)* describes the reserved 384KB at the top of the first megabyte of system memory on a PC/XT and the first megabyte on an AT-type system. This memory has the addresses from A0000 through FFFFF. The way the 384KB of upper memory is used breaks down as follows:

- *The first 128KB after conventional memory is called video RAM*. It is reserved for use by video adapters. When text and graphics are displayed onscreen, the data bits that make up those images reside in this space. Video RAM is allotted the address range A0000–BFFFF.
- *The next 128KB is reserved for the adapter BIOS that resides in read-only memory chips on some adapter boards plugged into the bus slots*. Most VGA-compatible video adapters use the first 32KB of this area for their onboard BIOSes. Any other adapters installed can use the rest. Many network adapters also use this area for special-purpose RAM called *shared memory*. Adapter ROM and special-purpose RAM is allotted the address range C0000–DFFFF.
- *The last 128KB of memory is reserved for motherboard BIOS (the basic input/output system, which is stored in read-only RAM chips or ROM)*. The POST and bootstrap loader, which handles your system at boot-up until the operating system takes over, also reside in this space. Most systems use only the last 64KB (or less) of this space, leaving the first 64KB or more free for remapping with memory managers. Some systems also include the CMOS Setup program in this area. The motherboard BIOS is allotted the address range E0000–FFFFF.

Not all the 384KB of reserved memory is fully used on most 16-bit and higher systems. For example, according to the PC standard, reserved video RAM begins at address A0000, which is right at the 640KB boundary. Normally, it is used for VGA graphics modes, whereas the monochrome and color text modes use B0000–B7FFF and B8000–BFFFF, respectively. Older non-VGA adapters used memory only in the B0000 segment. Different video adapters use varying amounts of RAM for their operations, depending mainly on the mode they are in. To the processor, however, it always appears as the same 128KB area, no matter how much RAM is really on the video card. This is managed by bank switching areas of memory on the card in and out of the A0000–BFFFF segments.

Although the top 384KB of the first megabyte was originally termed *reserved memory*, it is possible to use previously unused regions of this memory to load 16-bit device drivers (such as the ANSI.SYS screen driver that comes with DOS) and memory-resident programs (such as MOUSE.COM, the DOS mouse driver), which frees up the conventional memory they would otherwise require. Note that this does not affect 32-bit device drivers such as those used with Windows 9x, NT/2000, and so forth because they load into extended memory with no restrictions. The amount of free UMA space varies from system to system, depending mostly on the adapter cards installed on the system. For example, most video adapters, SCSI adapters, and some network adapters require some of this area for built-in ROMs or special-purpose RAM use.

Segment Addresses and Linear Addresses

See the Technical Reference section of the CD accompanying this book for a discussion of segment and linear addressing.

Video RAM Memory

A video adapter installed in your system uses a portion of your system's first megabyte of memory to hold graphics or character information for display, but this typically is used or active only when in basic VGA mode.

Note that even though a modern video card can have 64MB or more of onboard memory, only 128KB of this memory appears available to the system in the video RAM area. The rest of the memory is accessible only by the video processor (on the video card) directly, or by your system processor via a memory aperture positioned near the 4GB top of the system address space. Because this aperture can be configured differently by various cards, you should consult the technical documentation for your card or video chipset for more information.

When in basic VGA mode, such as when at a DOS prompt or when running in Windows safe mode, your processor can directly access up to 128KB of the video RAM from address A0000–BFFFFh. All modern video cards also have onboard BIOS normally addressed at C0000–C7FFFh, which is part of the memory space reserved for adapter card BIOS. Generally, the higher the resolution and color capabilities of the video adapter, the more system memory the video adapter uses, but again, that additional memory (past 128KB) is not usually accessible by the processor. Instead, the system tells the video chip what should be displayed, and the video chip generates the picture by putting data directly into the video RAM on the card.

In the standard system-memory map, a total of 128KB is reserved for use by the video card to store currently displayed information when in basic VGA modes. The reserved video memory is located in segments A000 and B000. The video adapter ROM uses additional upper memory space in segment C000. Even with the new multiple monitor feature in Windows 98, only one video card (the primary video card) is in the memory map; all others use no low system memory.

Note

The location of video adapter RAM is responsible for the infamous 640KB DOS conventional memory barrier. DOS can use all available contiguous memory in the first megabyte of memory up to the point where the video adapter RAM is encountered. The use of ancient video adapters, such as the MDA and CGA, can enable DOS access to more than 640KB of system memory. For more information, see Chapter 5 of *Upgrading and Repairing PCs, 10th Anniversary Edition*, included on the CD.

To learn how the older video adapters use the system's memory, see "Obsolete Video Adapter Types," also in Chapter 5 of the *10th Edition*.

Video Graphics Array Memory

All VGA-compatible cards, including those running in PCI or AGP slots, use all 128KB of the system allocated video RAM from A0000–BFFFF, but not all at once. This video RAM area is used depending on the mode the card is in. Figure 6.20 shows the VGA adapter memory map.

You can see that the typical VGA card uses a full 32KB of space for the onboard ROM containing driver code. Some VGA cards might use slightly less, but this is rare. The video RAM areas are active only when the adapter is in the particular mode designated. In other words, when a VGA adapter is in graphics mode, only segment A000 is used; when it is in color text mode, only the last half of segment B000 is used. Because the VGA adapter is almost never run in monochrome text mode, the first half of segment B000 remains unused (B0000–B7FFF). Figure 6.20 shows the standard motherboard ROM BIOS so that you can get an idea of how the entire UMA is laid out with this adapter.

```

Figure 6.20 The VGA adapter memory map.

Some systems incorporate the video adapter into the motherboard or even directly in the motherboard chipset. In these systems, even though the video BIOS and motherboard BIOS might be from the same manufacturer, they are always set up to emulate a standard VGA-type adapter card. In other words, the video BIOS appears in the first 32KB of segment C000 just as though a standalone VGA-type card were plugged into a slot. The built-in video circuit in these systems can be easily disabled with a switch or jumper, which then enables a conventional VGA-type card to be plugged in. By having the built-in VGA act exactly as though it were a separate card, disabling it allows a new adapter to be installed with no compatibility problems that might arise if the video drivers had been incorporated into the motherboard BIOS.

Adapter ROM and Special-Purpose RAM Memory

The second 128KB of upper memory beginning at segment C000 is reserved for the software programs, or BIOS, on the adapter boards plugged into the system slots. These BIOS programs are stored on special chips known as ROM. Most adapters today use EEPROM or Flash ROM, which can be erased and reprogrammed right in the system without removing the chip or card. Updating the Flash ROM is as simple as running the update program you get from the manufacturer and following the directions onscreen. It pays to check periodically with your card manufacturers to see whether they have Flash ROM updates for their cards.

ROM is useful for semipermanent programs that must always be present while the system is running, and especially for booting. Graphics boards, hard disk controllers, communications boards, and expanded memory boards, for example, are adapter boards that might have adapter ROM. These adapter ROMs are in an area of memory separate from the VGA video RAM and motherboard ROM areas.

On systems based on the 386 CPU chip or higher, memory managers that are included with DOS 6 or third-party programs can load device drivers and memory-resident programs into unused regions in the UMA.

To actually move the RAM usage on any given adapter requires that you consult the documentation for the card. Most older cards require that specific switches or jumpers be changed, and the settings will probably not be obvious without the manual. Most newer cards, especially those that are Plug and Play, enable these settings to be changed by software that comes with the card or the Device Manager program that goes with some of the newer operating systems, such as Windows 9x or Windows 2000 and newer.

Video Adapter BIOS

The video adapter ROM BIOS controls the video card during the boot sequence and anytime the system is in basic VGA modes (such as when running DOS). You also are using the video ROM BIOS code whenever you are running Windows in safe mode. All modern video adapters (even AGP cards) use 32KB for their onboard BIOS, from addresses C0000–C7FFF.

Depending on the basic VGA mode selected (color text, monochrome text, or VGA graphics), the video card uses some or all of the 128KB of upper memory beginning at segment C000. In addition, graphics cards can contain up to 64MB or more of onboard memory for use in their native high-resolution modes in which to store currently displayed data and more quickly fetch new screen data for display.

Hard Disk Controller and SCSI Host Adapter BIOS

The upper memory addresses C0000–DFFFF are also used for the built-in BIOS contained on many hard drive and SCSI controllers. Table 6.15 lists the amount of memory and the addresses commonly used by the BIOS contained on hard drive adapter cards.

Table 6.15 Memory Addresses Used by Various Hard Drive Adapter Cards

Disk Adapter Type	Onboard BIOS Size	BIOS Address Range
Most XT-compatible controllers	8KB	C8000–C9FFF
Most AT controllers	None	Drivers in motherboard BIOS
Most standard IDE adapters	None	Drivers in motherboard BIOS
Most enhanced IDE adapters	16KB	C8000–CBFFF
Some SCSI host adapters	16KB	C8000–CBFFF
Some SCSI host adapters	16KB	DC000–DFFFF

The hard drive or SCSI adapter card used on a particular system might use a different amount of memory, but it is most likely to use the memory segment beginning at C800 because this address is considered part of the IBM standard for personal computers. Virtually all the disk controller or SCSI adapters today that have an onboard BIOS allow the BIOS starting address to be easily moved in the C000 and D000 segments. The locations listed in Table 6.15 are only the default addresses that most of these cards use. If the default address is already in use by another card, you have to consult the documentation for the new card to see how to change the BIOS starting address to avoid any conflicts.

Figure 6.21 shows a sample memory map for an Adaptec AHA-2940 SCSI adapter.

Network Adapters

Network adapter cards can also use upper memory in segments C000 and D000. The exact amount of memory used and the starting address for each network card vary with the card's type and manufacturer. Some network cards do not use any memory at all. A network card might have two primary uses for memory. They are as follows:

- IPL (Initial Program Load or Boot) ROM
- Shared memory (RAM)

An IPL ROM is usually an 8KB ROM that contains a bootstrap loader program that enables the system to boot directly from a file server on the network. This enables the removal of all disk drives from the PC, creating a diskless workstation. Because no floppy or hard disk is in the system to boot from, the

IPL ROM gives the system the instructions necessary to locate an image of the operating system on the file server and load it as though it were on an internal drive. If you are not using your system as a diskless workstation, it is beneficial to disable any IPL ROM or IPL ROM socket on the adapter card. Note that many network adapters do not allow this socket to be disabled, which means that you lose the 8KB of address space for other hardware, even if the ROM chip is removed from the socket!

Shared memory refers to a small portion of RAM contained on the network card that is mapped into the PC's upper memory area. This region is used as a memory window onto the network and offers rapid data transfer from the network card to the system. IBM pioneered the use of shared memory for its first Token-Ring network adapters, and now shared memory is commonly used in other companies' network adapters. Shared memory first was devised by IBM because it found that transfers using the DMA channels were not fast enough in most systems. This mainly had to do with some quirks in the DMA controller and bus design, which especially affected 16-bit ISA bus systems. Network adapters that do not use shared memory use DMA or Programmed I/O (PIO) transfers to move data to and from the network adapter.

Although shared memory is faster than either DMA or PIO for ISA systems, it does require 16KB of UMA space to work. Most standard performance network adapters use PIO because it makes them easier to configure, and they require no free UMA space. However, most high-performance adapters use shared memory. The shared memory region on most network adapters that use one is usually 16KB in size and can be located at any user-selected 4KB increment of memory in segments C000 or D000.

Figure 6.22 shows the default memory addresses for the IPL ROM and shared memory of an IBM Token-Ring network adapter, although many other network adapters, such as Ethernet adapters, are similar. One thing to note is that most Ethernet adapters use either a DMA channel or standard PIO commands to send data to and from the network and don't use shared memory, as many Token-Ring cards do.

```

Figure 6.22 Network adapter default memory map.

I have also included the standard VGA video BIOS in Figure 6.22 because nearly every system would have a VGA-type video adapter as well. Note that these default addresses for the IPL ROM and the shared memory can easily be changed by reconfiguring the adapter. Most other network adapters are similar in that they also have an IPL ROM and a shared memory address, although the sizes of these areas and the default addresses might be different. Most network adapters that incorporate an IPL ROM option can disable the ROM and socket so that those addresses are not needed at all. This helps conserve UMA space and prevent possible future conflicts if you are never going to use the function.

Note that the Plug and Play feature in Win9x, Me, and Windows 2000 does not attempt to optimize memory use, only to resolve conflicts. Of course, with 32-bit drivers, the locations and sizes of free upper memory blocks don't really matter because 32-bit drivers are loaded into extended memory. If you are still occasionally running DOS-based programs, such as games, you could manually optimize the upper memory area configuration for maximum memory and performance, but for the most part it isn't worth the effort.

Motherboard BIOS Memory

The last 128KB of reserved memory is used by the motherboard BIOS. The BIOS programs in ROM control the system during the boot-up procedure and remain as drivers for various hardware in the system during normal operation. Because these programs must be available immediately, they can't be loaded from a device such as a disk drive.

◀◀ See Chapter 5, "BIOS," p. 345.

Both segments E000 and F000 in the memory map are considered reserved for the motherboard BIOS, but only some systems actually use this entire area. Older 8-bit systems require only segment F000 and enable adapter card ROM or RAM to use segment E000. Most 16-bit or greater systems use all F000 for the BIOS and might decode but not use any of segment E000. By decoding an area, the motherboard essentially grabs control of the addresses, which precludes installing any other hardware in this region. In other words, configuring adapter cards to use this area isn't possible. That is why you will find that most adapters that use memory simply do not allow any choices for memory use in segment E000. Although this might seem like a waste of 64KB of memory space, any 386 or higher system can use the powerful MMU in the processor to map RAM from extended memory into segment E000 as an upper memory block. The system can subsequently load 16-bit driver software in this UMB if necessary. This is a nice solution to what otherwise would be wasted memory, although it is not important if you use 32-bit drivers.

Figure 6.23 shows the motherboard ROM BIOS memory use of most 16-bit or greater systems.

```
. = Empty Addresses
R = Standard Motherboard ROM BIOS

      : 0---1---2---3---4---5---6---7---8---9---A---B---C---D---E---F---
0E0000: ................................................................
0F0000: RRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRRR
```

Figure 6.23 Motherboard ROM BIOS memory use of most systems.

Note that the standard system BIOS uses only segment F000 (64KB). In almost every case, the remainder of the BIOS area (segment E000) is completely free and can be used as UMA block space.

Extended Memory

As mentioned previously in this chapter, the memory map on a system based on the 286 or higher processor can extend beyond the 1MB boundary that exists when the processor is in real mode. On a 286 or 386SX system, the extended memory limit is 16MB (16-bit addressing); on a 386DX, 486, Pentium, Pentium MMX, or Pentium Pro system, the extended memory limit is 4GB (4,096MB, using 32-bit addressing). Systems based on the Pentium II and newer processors have a limit of 64GB (65,536MB, using 36-bit addressing).

For a system to address memory beyond the first megabyte, the processor must be in protected mode—the native mode of 286 and higher processors. On a 286, only programs designed to run in protected mode can take advantage of extended memory; 386 and higher processors offer another mode, called virtual real mode, which enables extended memory to be, in effect, chopped into 1MB pieces (each its own real-mode session). Virtual real mode also enables several of these sessions to be running simultaneously in protected areas of memory. They can be seen as DOS prompt sessions or windows within Windows 9x, NT, or OS/2. Although several DOS programs can be running at once, each is still limited to a maximum of 640KB of memory because each session simulates a real-mode environment, right down to the BIOS and Upper Memory Area. Running several programs at once in virtual real mode, called *multitasking*, requires software that can manage each program and keep them from crashing into one another. OS/2, Windows 9x, and Windows NT all do this.

The 286 and higher CPU chips also run in what is termed *real mode*, which enables full compatibility with the 8088 CPU chip installed on the PC/XT-type computer. Real mode enables you to run DOS programs one at a time on an AT-type system just as you would on a PC/XT. However, an AT-type system running in real mode, particularly a system based on the 386 through Pentium III or Athlon, is really functioning as little more than a turbo PC. In real mode, these processors can emulate the 8086 or 8088, but they can't operate in protected mode at the same time. For that reason, the 386 and above also provide a virtual real mode that operates under protected mode. This enables real-mode programs to execute under the control of a protected-mode operating system, such as Win9x/Me or NT/2000.

Note

Extended memory is basically all memory past the first megabyte, which can be accessed only while the processor is in protected mode.

XMS Memory

Microsoft, Intel, AST Corp., and Lotus Development developed the extended memory specification (XMS) in 1987 to specify how programs would use extended memory. The XMS specification functions on systems based on the 286 or higher and enables real-mode programs (those designed to run in DOS) to use extended memory and another block of memory usually out of the reach of DOS.

Before XMS, there was no way to ensure cooperation between programs that switched the processor into protected mode and used extended memory. There was also no way for one program to know what another had been doing with the extended memory because none of them could see that memory while in real mode. HIMEM.SYS becomes an arbitrator of sorts that first grabs all the extended memory for itself and then doles it out to programs that know the XMS protocols. In this manner, several programs that use XMS memory can operate together under DOS on the same system, switching the processor into and out of protected mode to access the memory. XMS rules prevent one program from accessing memory that another has in use. Because Windows 3.x is a program manager that switches the system to and from protected mode in running several programs at once, it has been set up to require XMS memory to function. Windows 95 operates mostly in protected mode, but still calls on real mode for access to many system components. Windows NT and Windows 2000 are true protected-mode operating systems, as is OS/2.

Extended memory can be made to conform to the XMS specification by installing a device driver in the `CONFIG.SYS` file. The most common XMS driver is HIMEM.SYS, which is included with Windows 3.x and later versions of DOS, starting with 4.0 and up. Windows 9x and NT automatically allow XMS functions in DOS prompt sessions, and you can configure full-blown DOS-mode sessions to allow XMS functions as well.

Note

To learn more about the high memory area and expanded memory, see Chapter 5 of *Upgrading and Repairing PCs, 10th Anniversary Edition*, on the CD.

Preventing ROM BIOS Memory Conflicts and Overlap

As explained previously, C000 and D000 are reserved for use by adapter-board ROM and RAM. If two adapters have overlapping ROM or RAM addresses, usually neither board operates properly. Each board functions if you remove or disable the other one, but they do not work together.

With many adapter boards, you can change the actual memory locations to be used with jumpers, switches, or driver software, which might be necessary to allow two boards to coexist in one system. This type of conflict can cause problems for troubleshooters. You must read the documentation for each adapter to find out which memory addresses the adapter uses and how to change the addresses to allow coexistence with another adapter. Most of the time, you can work around these problems by reconfiguring the board or by changing jumpers, switch settings, or software-driver parameters. This change enables the two boards to coexist and stay out of each other's way.

Additionally, you must ensure that adapter boards do not use the same IRQ, DMA channel, or I/O port address. You can easily avoid adapter board memory, IRQ, DMA channel, and I/O port conflicts by creating a chart or template to mock up the system configuration by penciling on the template the resources already used by each installed adapter. You end up with a picture of the system resources and the relationship of each adapter to the others.

If you are running a Plug and Play operating system, such as Windows 9x/Me or 2000, you can use the Device Manager to view and optionally print all the device settings. I highly recommend you use this to print out all the settings in your system before and after you make modifications to see what has been changed. This will help you anticipate conflicts and ensures that you configure each adapter board correctly the first time. The template also becomes important documentation when you consider new adapter purchases. New adapters must be configurable to use the available resources in your system.

◀◀ See "System Resources," p. 316.

If your system has Plug and Play capabilities, and you use PnP adapters, it can resolve conflicts between the adapters by moving the memory usage on any conflict. Unfortunately, this routine is not intelligent and still requires human intervention—that is, manual specification of addresses to achieve the most optimum location for the adapter memory.

ROM Shadowing

Virtually all 386 and higher systems enable you to use what is termed *shadow memory* for the motherboard and possibly some adapter ROMs as well. Shadowing essentially moves the programming code from slow ROM chips into fast 32-bit system memory. Shadowing slower ROMs by copying their contents into RAM can greatly speed up these BIOS routines—sometimes making them four to five times faster.

Note that shadowing ROMs is not very important when running a 32-bit operating system, such as Win9x/Me or NT/2000. This is because those operating systems use the 16-bit BIOS driver code only during booting; then they load 32-bit replacement drivers into faster extended memory and use them. Therefore, shadowing normally affects only DOS or other 16-bit software and operating systems. Because of this, some people are tempted to turn off the Video BIOS shadowing feature in the BIOS setup. Unfortunately, it won't gain you any memory back (you've lost it anyway) and will make the system slightly slower to boot up and somewhat slower when in Windows safe mode. The 16-bit BIOS video driver code is used at those times.

Note

To learn more about ROM shadowing, see Chapter 5 of *Upgrading and Repairing PCs, 10th Anniversary Edition*, on the CD accompanying this book.

Total Installed Memory Versus Total Usable Memory

Most people don't realize that not all the RAM you purchase and install in a system is available. Because of some quirks in system design, the system usually has to "throw away" up to 384KB of RAM to make way for the Upper Memory Area.

For example, most systems with 16MB of RAM (which is 16,384KB) installed show a total of only 16,000KB installed during the POST or when running Setup. This indicates that 16,384KB–16,000KB = 384KB of missing memory! Some systems might show 16,256KB with the same 16MB installed, which works out to 16,384KB–16,256KB = 128KB missing.

If you run your Setup program and check out your base and extended memory values, you will find more information than just the single figure for the total shown during the POST. In most systems with 4,096KB (4MB), you have 640KB base and 3,072KB extended. In some systems, Setup reports 640KB base and 3,328KB extended memory, which is a bonus. In other words, most systems come up 384KB short, but some come up only 128KB short.

This shortfall is not easy to explain, but it is consistent from system to system. Say that you have a 486 system with two installed 72-pin (32-bit) 16MB SIMMs. This results in a total installed memory of 32MB in two separate banks because the processor has a 32-bit data bus. Each SIMM is a single bank in this system. The first bank (or SIMM, in this case) starts at address 0000000h (the start of the first megabyte), and the second starts at 1000000 (the start of the seventeenth megabyte).

One of the cardinal rules of memory is that you absolutely cannot have two hardware devices wired to the same address. This means that 384KB of the first memory bank in this system would be in direct conflict with the video RAM (segments A000 and B000), any adapter card ROMs (segments C000 and D000), and of course the motherboard ROM (segments E000 and F000). That means all SIMM RAM that occupies these addresses must be shut off; otherwise, the system will not function! Actually, a motherboard designer can do three things with the SIMM memory that would overlap from A0000–FFFFF:

- Use the faster RAM to hold a copy of any slow ROMs (shadowing), disabling the ROM in the process
- Turn off any RAM not used for shadowing, eliminating any UMA conflicts
- Remap any RAM not used for shadowing, adding to the stack of currently installed extended memory

Most systems shadow the motherboard ROM (usually 64KB) and the video ROM (32KB) and simply turn off the rest. Some motherboard ROMs allow additional shadowing to be selected between C8000 and DFFFF, usually in 16KB increments.

Note

You can shadow only ROM, never RAM, so if any card (such as a network card) has a RAM buffer in the C8000–DFFFF area, you must not shadow the RAM buffer addresses; otherwise, the card will not function. For the same reason, you can't shadow the A0000–BFFFF area because it is the video adapter RAM buffer.

Most motherboards do not do any remapping, which means that any of the 384KB not shadowed is simply turned off. That is why enabling shadowing does not seem to use any memory. The memory used for shadowing would otherwise be discarded in most systems. These systems would appear to be short by 384KB compared to what is physically installed in the system. For example, in a system with 32MB, no remapping would result in 640KB of base memory and 31,744KB of extended memory, for a total of 32,384KB of usable RAM—384KB short of the total (32,768KB–384KB).

Systems that show 384KB of "missing" memory do not do remapping. If you want to determine whether your system has any missing memory, all you need to know are three things. One is the total physical memory actually installed. Running your Setup program can discover the other two items. You want to know the total base and extended memory numbers recognized by the system. Then simply subtract the base and extended memory from the total installed to determine the missing memory. You usually will find that your system is missing 384KB, but you could be lucky and have a system that remaps 256KB of what is missing and thus shows only 128KB of memory missing.

Virtually all systems use some of the missing memory for shadowing ROMs, especially the motherboard and video BIOS, so what is missing is not completely wasted. Systems missing 128KB will find that it is being used to shadow your motherboard BIOS (64KB from F0000 to FFFFF) and video BIOS (32KB from C0000 to C8000). The remainder of segment C0000 (32KB from C8000 to CFFFF) is simply being turned off. All other segments (128KB from A0000 to BFFFF and 128KB from D0000 to EFFFF) are being remapped to the start of the fifth megabyte (400000–43FFFF). Most systems simply disable these remaining segments rather than take the trouble to remap them.

Adapter Memory Configuration and Optimization

Adapter boards use upper memory for their BIOS and as working RAM. If two boards attempt to use the same BIOS area or RAM area of upper memory, a conflict occurs that can keep your system from booting. In most cases, the plug-and-play software in the operating system ensures that such cards are automatically reconfigured so that they are not in conflict; however, sometimes problems can occur and you must step in and manually resolve a conflict. The following sections cover ways to avoid these potential unresolved conflicts and how to troubleshoot if they do occur. In addition, these sections discuss moving adapter memory to resolve conflicts and provide some ideas on optimizing adapter memory use.

How to Determine What Adapters Occupy the UMA

You can determine which adapters are using space in upper memory in the following two ways:

- Study the documentation for each adapter on your system to determine the memory addresses they use.
- Use a software utility or the Device Manager in your operating system to determine which upper memory areas your adapters are using.

The simplest way (although by no means always the most foolproof) is to use a software utility to determine the upper memory areas used by the adapters installed on your system. One such utility, Microsoft Diagnostics (MSD), comes with Windows 3.x and DOS 6 or higher versions. The Device Manager under System in the Windows 9x/Me and 2000 Control Panel also supplies this information, as does the new System Information utility that comes with Windows 98/Me. These utilities examine your system configuration and determine not only the upper memory used by your adapters, but also the IRQs used by each of these adapters.

True plug-and-play systems also shut down one of the cards involved in a conflict to prevent a total system lockup. This could cause Windows to boot in safe mode.

After you run MSD, Device Manager, or another utility to determine your system's upper memory configuration, make a printout of the memory addresses used. Thereafter, you can quickly refer to the printout when you are adding a new adapter to ensure that the new board does not conflict with any devices already installed on your system.

Moving Adapter Memory to Resolve Conflicts

After you identify a conflict or potential conflict using one of the two methods discussed in the previous section, you might have to reconfigure one or more of your adapters to move the upper memory space used by a problem adapter.

Most adapter boards make moving adapter memory a somewhat simple process, enabling you to change a few jumpers or switches to reconfigure the board. With plug-and-play cards, use the configuration program that comes with the board or the Windows Device Manager to make the changes. The following steps help you resolve most problems that arise because adapter boards conflict with one another:

1. Determine the upper memory addresses currently used by your adapter boards and write them down.
2. Determine whether any of these addresses are overlapping, which results in a conflict.
3. Consult the documentation for your adapter boards to determine which boards can be reconfigured so that all adapters have access to unique memory addresses.
4. Configure the affected adapter boards so that no conflict in memory addresses occurs.

For example, if one adapter uses the upper memory range C8000–CBFFF and another adapter uses the range CA000–CCFFF, you have a potential address conflict. One of them must be changed. Note that plug-and-play cards allow these changes to be made directly from the Windows Device Manager.

CHAPTER 7

The IDE Interface

An Overview of the IDE Interface

The primary interface used to connect a hard disk drive to a modern PC is typically called IDE (Integrated Drive Electronics). An interesting fact is that the true name of the interface is called ATA (AT Attachment), which refers to the fact that this interface originally was designed to connect a combined drive and controller directly to the bus of the 1984 vintage IBM AT computer, otherwise known as the ISA (Industry Standard Architecture) bus. *IDE* is a term originated by the marketing departments of some drive manufacturers to describe the drive/controller combination used in drives with the ATA interface. Integrated Drive Electronics refers to the fact that the interface electronics or controller is built into the drive and is not a separate board, as with earlier drive interfaces. Although technically the correct name for the interface is ATA, many persist in using the IDE designation today. Throughout this book, I will use both designations because they are essentially interchangeable. If you are being picky, you could say that *IDE* refers generically to any drive interface in which the controller is built into the drive, whereas *ATA* refers to the specific implementation of IDE that is used in PCs.

Today, ATA is used to connect not only hard disks, but also CD-ROM and CD-RW drives, DVD drives, high-capacity SuperDisk floppy drives, and tape drives. Even so, ATA is still thought of primarily as a hard disk interface, and it evolved directly from the separate controller and hard drive interfaces that were used prior to ATA. This chapter covers the ATA interface in detail, as well as the original interfaces from which ATA evolved. Because the ATA interface is directly integrated into virtually all motherboard chipsets, ATA is the primary storage interface used by most PCs.

Note

Even Apple has recognized the value of ATA and has incorporated it into virtually all modern Macintosh systems.

▶▶ See "LS-120 (120MB) SuperDisk Drives," p. 647.

Precursors to IDE

A variety of hard disk interfaces have been available for PC hard disks over the years. As time has passed, the number of choices has increased, and many older designs are no longer viable in newer systems.

The primary job of the hard disk controller or interface is to transmit and receive data to and from the drive. The various interface types limit how fast data can be moved from the drive to the system and offer different features as well as levels of performance. If you are putting together a system in which performance is a primary concern, you need to know how these various interfaces affect performance and what you can expect from them. Many statistics that appear in technical literature are not indicative of the real performance figures you will see in practice. I will separate the myths presented by some of these overly optimistic figures from the reality of what you will actually see.

Several types of hard disk interfaces have been used in PC systems over the years, as shown here:

Interface	When Used
ST-506/412	1978–1989
ESDI	1983–1991
SCSI	1986–Present
ATA (IDE)	1986–Present
Serial ATA	2001–Present

Of these interfaces, only ST-506/412 and ESDI are what you could call true disk-controller–to–drive interfaces, and they are obsolete. SCSI and ATA are system-level interfaces that usually incorporate a chipset-based controller interface internally. For example, most SCSI and ATA drives incorporate the same basic internal controller circuitry. The SCSI interface adds another layer of interface that attaches the controller to the system bus, whereas ATA is a more direct bus-attachment interface. Virtually all modern disk drives use either ATA or SCSI interfaces to connect to a system.

The IDE Interface

As discussed earlier, IDE (now officially referred to as ATA) is a generic term that applies to any drive with a built-in disk controller. It is an ANSI standard, or more accurately an evolving standard with various published standard versions. The term IDE can roughly apply to any disk drive with a built-in controller, whereas ATA denotes a specific interface. Referring to the original parallel version of the interface, what we call ATA originally referred to a hard disk drive that plugged directly into a version of the AT-bus, more commonly known as the 16-bit ISA bus.

ATA is a 16-bit parallel interface, meaning that 16 bits are transmitted simultaneously down the interface cable. A new interface called Serial ATA was officially introduced in late 2000 and is being adopted in systems starting in 2001. Serial ATA (SATA) sends 1 bit down the cable at a time, enabling thinner and smaller cables to be used, as well as providing higher performance due to the higher cycling speeds allowed. SATA is a completely new and updated physical interface design, while remaining compatible on the software level with parallel ATA. Throughout this book, *ATA* refers to the parallel version, whereas Serial ATA is explicitly referenced as SATA.

The first drives with integrated ISA bus (otherwise known as AT-bus) controllers were called *hardcards*; they consisted of a hard disk bolted directly to an ISA bus controller card and plugged into a slot as a single unit. Today, any drive with an integrated controller is called an IDE drive, although normally when we say *IDE*, we really mean the specific version of IDE called ATA. No matter what you call it, combining the drive and controller greatly simplifies installation because there are no separate power or signal cables from the controller to the drive. Also, when the controller and drive are assembled as a unit, the number of total components is reduced, signal paths are shorter, and the electrical connections are more noise-resistant. This results in a more reliable design than is possible when a separate controller, connected to the drive by cables, is used.

Placing the controller, including the digital-to-analog encoder/decoder (endec) on the drive offers an inherent reliability advantage over interfaces with separate controllers. Reliability is increased because the data encoding, from digital to analog, is performed directly on the drive in a tight noise-free environment. The timing-sensitive analog information does not have to travel along crude ribbon cables that are likely to pick up noise and insert propagation delays into the signals. The integrated configuration enables increases in the clock rate of the encoder and the storage density of the drive.

Integrating the controller and drive also frees the controller and drive engineers from having to adhere to the strict guidelines imposed by the earlier interface standards. Engineers can design what essentially are custom drive and controller implementations because no other controller will ever have to be connected to the drive. The resulting drive and controller combinations can offer higher performance than earlier standalone controller and drive setups. IDE drives sometimes are called drives with embedded controllers.

The ATA connector on motherboards in many systems started out as nothing more than a stripped-down ISA bus (AT-bus) slot. These connectors contain what started out as a 40-pin subset of the 98 pins that would make up a standard 16-bit ISA bus slot. Note that smaller 2 1/2-inch ATA drives use a superset 44-pin connection, which includes additional pins for power. The pins from the original ISA bus used in ATA are the only signal pins required by a standard-type AT hard disk controller. For example, because a primary AT-style disk controller uses only interrupt request (IRQ) line 14, the primary motherboard ATA IDE connector supplies only that IRQ line; no other IRQ lines are necessary. The obsolete 8-bit XT IDE motherboard connector supplied interrupt line 5 because that is what an XT controller used. Note that even if your ATA interface is integrated within the motherboard chipset South Bridge or I/O Controller Hub chip (as it would be in newer systems) and runs at higher bus speeds, the pinout and functions of the pins are still the same as the original design taken right off the ISA bus.

◀◀ See "Motherboard Interface Connectors," p. 285.

◀◀ See "The ISA Bus," p. 300.

Note

Many people who use systems with ATA connectors on the motherboard believe that a hard disk controller is built into their motherboards, but in a technical sense the controller is actually in the drive. Although the integrated ATA ports on a motherboard often are referred to as *controllers*, they are more accurately called *host adapters* (although you'll rarely hear this term). A host adapter can be thought of as a device that connects a controller to a bus.

When IDE drives are discussed, the ATA variety usually is the only kind mentioned because it is by far the most popular—and pretty much the only type in use in modern PCs. But other forms of IDE drives existed, based on other buses. For example, several PS/2 systems came with Micro-Channel (MCA)–based IDE drives that plugged directly into a Micro-Channel bus slot (through an interposer card). An 8-bit ISA form of IDE also existed but was never very popular. Most PCs use AT-Bus (16-bit)–based IDE drives, officially known as ATA drives. Many new systems are built using the Serial ATA interface as well. The ATA/IDE interfaces are by far the most popular type of drive interfaces available.

Note

IDE is a generic name that could be given to any interface in which the controller portion of the circuit is on the drive; ATA and Serial ATA refer to specific types of IDE interfaces. Because the popular form of IDE interface is ATA, the terms often are used interchangeably, even though on a technical level that is not correct. What most people call IDE is more properly called ATA.

The primary advantage of ATA drives over the older separate controller–based interfaces and newer host bus interface alternatives, such as SCSI and IEEE-1394 (iLink or FireWire), is cost. Because the separate controller or host adapter is eliminated and the cable connections are simplified, ATA drives cost much less than a standard controller and drive combination.

▶▶ See "Small Computer System Interface," p. 514.

▶▶ See "USB and IEEE-1394 (i.Link or FireWire)—Serial and Parallel Port Replacements," p. 940.

Another advantage is performance. ATA drives are some of the highest performance drives available—but they also are among the lowest performance drives. This apparent contradiction is a result of the fact that all ATA drives are different. You cannot make a blanket statement about the performance of ATA drives because each drive is unique. The high-end models, however, offer performance equal or superior to that of any other type of drive on the market for a single-user, single-tasking operating system.

IDE Origins

The earliest IDE drives were called hardcards and were nothing more than hard disks and controllers bolted directly together and plugged into a slot as a single unit. Companies such as the Plus

Development Division of Quantum took small 3 1/2-inch drives (either ST-506/412 or ESDI) and attached them directly to a standard controller. The assembly then was plugged into an ISA bus slot as though it were a normal disk controller. Unfortunately, the mounting of a heavy, vibrating hard disk in an expansion slot with nothing but a single screw to hold it in place left a lot to be desired—not to mention the possible interference with adjacent cards because many of these units were much thicker than a controller card alone.

Several companies got the idea to redesign the controller to replace the logic-board assembly on a standard hard disk and then mount it in a standard drive bay just like any other drive. Because the built-in controller in these drives still needed to plug directly into the expansion bus just like any other controller, a cable was run between the drive and one of the slots.

These connection problems were solved in various ways. Compaq was the first to incorporate a special bus adapter in its system to adapt the 98-pin AT (ISA) bus edge connector on the motherboard to a smaller 40-pin header style connector the drive would plug into. The 40-pin connectors were all that was necessary because it was known that a disk controller never would need more than 40 of the ISA bus lines.

In 1987, IBM developed its own MCA IDE drives and connected them to the bus through a bus adapter device called an *interposer card*. These bus adapters (sometimes called *paddle boards* or *angle boards*) needed only a few buffer chips and did not require any real circuitry because the drive-based controller was designed to plug directly into the bus. The paddle board nickname came from the fact that they resembled game paddle or joystick adapters, which do not have much circuitry on them. Another 8-bit variation of IDE appeared in 8-bit ISA systems, such as the PS/2 Model 30. The XT IDE interface uses a 40-pin connector similar to, but not compatible with, the 16-bit version.

IDE Bus Versions

There have been four main types of IDE interfaces based on three bus standards:

- Serial AT Attachment (SATA)
- Parallel AT Attachment (ATA) IDE (based on 16-bit ISA)
- XT IDE (based on 8-bit ISA)
- MCA IDE (based on 16-bit Micro Channel)

Of these, only the ATA versions are used today. ATA and Serial ATA have evolved with newer, faster, and more powerful versions. The improved versions of parallel ATA are referred to as ATA-2 and higher. They are also sometimes called EIDE (Enhanced IDE), Fast-ATA, Ultra-ATA, or Ultra-DMA. Even though ATA appears to have hit the end of the road with ATA-6, Serial ATA picks up where ATA leaves off and offers greater performance plus an established roadmap for future upgrades.

Note

Many people are confused about 16- versus 32-bit bus connections and 16- versus 32-bit hard drive connections. A PCI bus connection allows for a 32-bit (and possibly 64-bit in the future) connection between the bus and the IDE host interface, which is normally in the motherboard chipset South Bridge or I/O Controller Hub (ICH) chip. However, the actual parallel ATA interface between the host connector on the motherboard and the drive (or drives) itself is only a 16-bit interface. Thus, in a parallel ATA drive configuration, you are still getting only 16-bit transfers between the drive and the motherboard-based host interface. Even so, the clock speeds of the ATA interface are high enough that one or two hard drives normally cannot supply the controller enough data to saturate even a 16-bit channel. The same is true with Serial ATA, which—although it transmits only 1 bit at a time—does so at extremely high speeds.

The obsolete XT and current parallel ATA versions have standardized on 40-pin connectors and cables, but the connectors have slightly different pinouts, rendering them incompatible with one another. MCA IDE is also obsolete, uses a completely different 72-pin connector, and is designed for MCA bus systems only.

In most modern systems you will find two ATA connectors on the motherboard. If your motherboard does not have one of these connectors and you want to attach an ATA drive to your system, you can purchase an adapter card that adds an ATA interface (or two) to a system via the ISA or PCI bus slots. Some of the cards offer additional features, such as an onboard ROM BIOS or cache memory.

Because the ATA variety of IDE is the primary one in use today, that is what most of this chapter discusses.

ATA IDE

Control Data Corporation (CDC), Western Digital, and Compaq actually created what could be called the first ATA-IDE interface drive and were the first to establish the 40-pin ATA connector pinout. The first ATA IDE drives were 5 1/4-inch half-height CDC 40MB units with integrated WD controllers sold in the first Compaq 386 systems in 1986.

Eventually, the 40-pin ATA connector and drive interface design was placed before one of the ANSI standards committees that, in conjunction with drive manufacturers, ironed out some deficiencies, tied up some loose ends, and then published what was known as the CAM ATA (Common Access Method AT Attachment) interface. The CAM Committee was formed in October 1988, and the first working document of the AT Attachment interface was introduced in March 1989. Before the CAM ATA standard, many companies that followed CDC, such as Conner Peripherals, made proprietary changes to what had been done by CDC. As a result, many older ATA drives from the late 1980s are very difficult to integrate into a dual-drive setup that has newer drives. By the early 1990s, most drive manufacturers brought their drives into full compliance with the official standard, which eliminated many of these compatibility problems.

Some areas of the ATA standard have been left open for vendor-specific commands and functions. These vendor-specific commands and functions are the main reason it is so difficult to low-level format ATA drives. To work to full capability, the formatter you are using usually must know the specific vendor-unique commands for rewriting sector headers and remapping defects. Unfortunately, these and other specific drive commands differ from OEM to OEM, clouding the “standard” somewhat. Most ATA drive manufacturers have formatting software available on their Web sites.

Note

It is important to note that only the ATA IDE interface has been standardized by the industry. The XT IDE and MCA IDE never were adopted as industry-wide standards and never became very popular. These interfaces no longer are in production, and no new systems of which I am aware come with these nonstandard IDE interfaces.

ATA Standards

Today what we call the ATA interface is controlled by an independent group of representatives from major PC, drive, and component manufacturers. This group is called Technical Committee T13 and is responsible for all interface standards relating to the parallel AT Attachment storage interface. T13 is a part of the National Committee on Information Technology Standards (NCITS), which operates under rules approved by the American National Standards Institute (ANSI), a governing body that sets rules which control nonproprietary standards in the computer industry as well as many other industries. A second group called the Serial ATA Workgroup has formed to create the Serial ATA standards that will also come under ANSI control. Although these are different groups, many of the same people are in both groups. It seems as if little further development will be done on parallel ATA past the ATA-6 (ATA/100) specification. The further evolution of ATA will be in the Serial ATA form (discussed later in this chapter).

The rules these committees operate under are designed to ensure that voluntary industry standards are developed by the consensus of people and organizations in the affected industry. NCITS specifically develops Information Processing System standards, whereas ANSI approves the process under which they are developed and publishes them. Because T13 is essentially a public organization, all the working drafts, discussions, and meetings of T13 are open for all to see.

The parallel ATA interface has evolved into several successive standard versions, introduced as follows:

- ATA-1 (1986–1994)
- ATA-2 (1996; also called Fast-ATA, Fast-ATA-2, or EIDE)
- ATA-3 (1997)
- ATA-4 (1998; also called Ultra-ATA/33)
- ATA-5 (1999–present; also called Ultra-ATA/66)
- ATA-6 (2000–present; also called Ultra-ATA/100)

Each version of ATA is backward compatible with the previous versions. In other words, older ATA-1 or ATA-2 devices work fine on ATA-4, ATA-5, and ATA-6 interfaces. In cases in which the device version and interface version don't match, they work together at the capabilities of the lesser of the two. Newer versions of ATA are built on older versions and with few exceptions can be thought of as extensions of the previous versions. This means that ATA-6, for example, is generally considered equal to ATA-5 with the addition of some features.

Table 7.1 breaks down the various ATA standards. The following sections describe all the ATA versions in more detail.

Table 7.1 ATA Standards

Standard	Timeframe	PIO Modes	DMA Modes	Ultra-DMA Modes	Speed[1]	Features
ATA-1	1986–1994	0–2	0	—	8.33	Drive support up to 136.9GB BIOS issues not addressed
ATA-2	1995–1996	0–4	0–2	—	16.67	Faster PIO modes; CHS/LBA BIOS translation defined up to 8.4GB; PC Card
ATA-3	1997	0–4	0–2	—	16.67	SMART[2]; improved signal integrity; LBA support mandatory; eliminated single-word DMA modes
ATA-4	1998	0–4	0–2	0–2	33.33	Ultra-DMA modes; BIOS support up to 136.9GB
ATA-5	1999–2000	0–4	0–2	0–4	66.67	Faster UDMA modes; 80-pin cable with autodetection

Table 7.1 Continued

Standard	Timeframe	PIO Modes	DMA Modes	Ultra-DMA Modes	Speed[1]	Features
ATA-6	2001–present	0–4	0–2	0–5	100.00	100MB/sec UDMA mode; extended drive and BIOS support up to 144PB[3]

1. Speed is MB/sec

2. SMART = Self-Monitoring, Analysis, and Reporting Technology

3. PB = Petabyte; 1PB is equal to 1 quadrillion bytes

MB = Millions of bytes

GB = Billions of bytes

CHS = Cylinder head sector

LBA = Logical block address

UDMA = Ultra DMA (Direct Memory Access)

ATA-1 (AT Attachment Interface for Disk Drives)

Although ATA-1 had been used since 1986 before being published as a standard, and although it was first published in 1988 in draft form, ATA-1 wasn't officially approved as a standard until 1994 (committees often work slowly). ATA-1 defined the original AT Attachment interface, which was an integrated bus interface between disk drives and host systems based on the ISA (AT) bus. The major features that were introduced and documented in the ATA-1 specification are

- 40/44-pin connectors and cabling
- Master/slave or cable select drive configuration options
- Signal timing for basic PIO (Programmed I/O) and DMA (Direct Memory Access) modes
- CHS (cylinder head sector) and LBA (logical block address) drive parameter translations supporting drive capacities up to $2^{28}–2^{20}$ (267,386,880) sectors, or 136.9GB

ATA-1 was officially published as ANSI X3.221-1994, AT Attachment Interface for Disk Drives, and was officially withdrawn on August 6, 1999. ATA-2 and later are considered backward-compatible replacements.

Although ATA-1 supported theoretical drive capacities up to 136.9GB ($2^{28}–2^{20}$ = 267,386,880 sectors), it did not address BIOS limitations that stopped at 528MB (1024×16×63 = 1,032,192 sectors). The BIOS limitations would be addressed in subsequent ATA versions because, at the time, no drives larger than 528MB had existed.

ATA-2 (AT Attachment Interface with Extensions-2)

Approved in 1996, ATA-2 was a major upgrade to the original ATA standard. Perhaps the biggest change was almost a philosophical one. ATA-2 was updated to define an interface between host systems and storage devices in general and not only disk drives. The major features added to ATA-2 as compared to the original ATA standard include

- Faster PIO and DMA transfer modes
- Support for power management
- Support for removable devices
- PCMCIA (PC card) device support
- Identify Drive command reports more information
- Defined standard CHS/LBA translation methods for drives up to 8.4GB in capacity

The most important additions in ATA-2 were the support for faster PIO and DMA modes, as well as methods to enable BIOS support up to 8.4GB. The BIOS support was necessary because, although even ATA-1 was designed to support drives of up to 136.9GB in capacity, the PC BIOS could originally handle drives of up to 528MB. Adding parameter-translation capability now allowed the BIOS to handle drives up to 8.4GB. This is discussed in more detail later in this chapter.

ATA-2 also featured improvements in the Identify Drive command that enabled a drive to tell the software exactly what its characteristics are; this is essential for both Plug and Play (PnP) and compatibility with future revisions of the standard.

ATA-2 was also known by unofficial marketing terms such as fast-ATA or fast-ATA-2 (Seagate/Quantum) and EIDE (Enhanced IDE, Western Digital). ATA-2 was officially published as ANSI X3.279-1996 AT Attachment Interface with Extensions.

ATA-3 (AT Attachment Interface-3)

First published in 1997, ATA-3 was a comparatively minor revision to the ATA-2 standard that preceded it. It consisted of a general cleanup of the specification and had mostly minor clarifications and revisions. The most major changes included the following:

- Eliminated single-word (8-bit) DMA transfer protocols.
- Added S.M.A.R.T. (Self-Monitoring, Analysis, and Reporting Technology) support for prediction of device performance degradation.
- LBA mode support was made mandatory (previously it had been optional).
- Added security mode, allowing password protection for device access.
- Recommendations for source and receiver bus termination to solve noise issues at higher transfer speeds.

ATA-3 has been officially published as ANSI X3.298-1997, AT Attachment 3 Interface.

ATA-3, which builds on ATA-2, adds improved reliability, especially of the faster PIO mode 4 transfers; however, ATA-3 does not define any faster modes. ATA-3 also adds a simple password-based security scheme, more sophisticated power management, and S.M.A.R.T. This enables a drive to keep track of problems that might result in a failure and therefore avoid data loss. S.M.A.R.T. is a reliability prediction technology that was initially developed by IBM.

ATA/ATAPI-4 (AT Attachment with Packet Interface Extension-4)

First published in 1998, ATA-4 included several important additions to the standard. It included the Packet Command feature known as the AT Attachment Packet Interface (ATAPI), which allowed devices such as CD-ROM and CD-RW drives, LS-120 SuperDisk floppy drives, tape drives, and other types of storage devices to be attached through a common interface. Until ATA-4 came out, ATAPI was a separately published standard. ATA-4 also added the 33MB/sec transfer mode known as Ultra-DMA or Ultra-ATA. ATA-4 is backward compatible with ATA-3 and earlier definitions of the ATAPI. The major revisions added in ATA-4 were as follows:

- Ultra-DMA (UDMA) transfer modes up to Mode 2, which is 33MB/sec (called UDMA/33 or Ultra-ATA/33)
- Integral ATAPI support
- Advanced power management support
- Defined an optional 80-conductor, 40-pin cable for improved noise resistance

- Compact Flash Adapter (CFA) support
- Introduced enhanced BIOS support for drives over 9.4ZB (zettabytes or trillion gigabytes) in size (even though ATA was still limited to 136.9GB)

ATA-4 was published as ANSI NCITS 317-1998, ATA-4 with Packet Interface Extension.

The speed and level of ATA support in your system is mainly dictated by your motherboard chipset. Most motherboard chipsets come with a component called either a South Bridge or an I/O Controller Hub that provides the ATA interface (as well as other functions) in the system. Check the specifications for your motherboard or chipset to see whether yours supports the faster ATA/33, ATA/66, or ATA/100 mode. One indication is to enter the BIOS Setup, put the hard disk on manual parameter settings (user defined), and see which if any Ultra-DMA modes are listed. Most boards built during 1998 support ATA/33; in 2000 they began to support ATA/66; and by late 2000 most started supporting ATA/100.

◀◀ See "Chipsets," p. 225.

ATA-4 made ATAPI support a full part of the ATA standard, and thus ATAPI was no longer an auxiliary interface to ATA but merged completely within. This promoted ATA for use as an interface for many other types of devices. ATA-4 also added support for new Ultra-DMA modes (also called Ultra-ATA) for even faster data transfer. The highest-performance mode, called UDMA/33, had 33MB/second bandwidth—twice that of the fastest programmed I/O mode or DMA mode previously supported. In addition to the higher transfer rate, because UDMA modes relieve the load on the processor, further performance gains were realized.

An optional 80-conductor cable (with cable select) is defined for UDMA/33 transfers. Although this cable was originally defined as optional, it would later be required for the faster ATA/66 and ATA/100 modes in ATA-5 and later.

Also included was support for queuing commands, which is similar to that provided in SCSI-2. This enabled better multitasking as multiple programs make requests for IDE transfers.

▶▶ See "SCSI Versus IDE," p. 540.

ATA/ATAPI-5 (AT Attachment with Packet Interface-5)

This version of the ATA standard was approved in early 2000 and builds on ATA-4. The major additions in the standard include the following:

- Ultra-DMA (UDMA) transfer modes up to Mode 4, which is 66MB/sec (called UDMA/66 or Ultra-ATA/66).
- 80-conductor cable now mandatory for UDMA/66 operation.
- Added automatic detection of 40- or 80-conductor cables.
- UDMA modes faster than UDMA/33 are enabled only if an 80-conductor cable is detected.

Another standard recently approved by the T13 committee is an IEEE-1394 (iLink or FireWire) extension to the ATA interface protocol. This specifies a bridge protocol between the iLink/FireWire bus and ATA, allowing ATA drives to be adapted to this newer interface.

▶▶ See "IEEE-1394," p. 948.

Copies of any of the published standards can be purchased from ANSI or Global Engineering Documents (see the Vendor List on the CD).

ATA-5 includes Ultra-ATA/66 (also called Ultra-DMA or UDMA/66), which doubles the Ultra-ATA burst transfer rate by reducing setup times and increasing the clock rate. The faster clock rate increases interference, which causes problems with the standard 40-pin cable used by ATA and Ultra-ATA. To eliminate noise and interference, the new 40-pin, 80-conductor cable has now been made mandatory for drives running in UDMA/66 or faster modes. This cable was first announced in ATA-4 but is now mandatory in ATA-5 to support the Ultra-ATA/66 mode. This cable adds 40 additional ground lines between each of the original 40 ground and signal lines, which help shield the signals from interference. Note that this cable works with older non–Ultra-ATA devices as well because it still has the same 40-pin connectors.

The 40-pin, 80-conductor cables will support the cable select feature and have color-coded connectors. The blue (end) connector should be connected to the ATA host interface (usually the motherboard). The black (opposite end) connector is known as the *master position*, which is where the primary drive plugs in. The gray (middle) connector is for slave devices.

To use either the UDMA/33 or UDMA/66 mode, your ATA interface, drive, BIOS, and cable must be capable of supporting the mode you want to use. The operating system also must be capable of handling Direct Memory Access. Windows 95 OSR2 or later, Windows 98/Me, and Windows 2000/XP are ready out of the box, but older versions of Windows 95 and NT (prior to Service Pack 3) require additional or updated drivers to fully exploit these faster modes.

For reliability, Ultra-DMA modes incorporate an error-detection mechanism known as *cyclical redundancy checking (CRC)*. CRC is an algorithm that calculates a checksum used to detect errors in a stream of data. Both the host (controller) and the drive calculate a CRC value for each Ultra-DMA transfer. After the data is sent, the drive calculates a CRC value, and this is compared to the original host CRC value. If a difference is reported, the host might be required to select a slower transfer mode and retry the original request for data.

ATA/ATAPI-6 (AT Attachment with Packet Interface-6)

This final version of the ATA standard was under development during 2001 and builds on ATA-5. The major additions in the standard include the following:

- Ultra-DMA (UDMA) transfer modes up to Mode 5, which is 100MB/sec (called UDMA/100, Ultra-ATA/100, or just ATA/100)
- LBA addressing extended to 2^{48} (281,474,976,710,656) sectors supporting drives up to 144.12PB (petabytes = quadrillion bytes)

ATA-6 includes Ultra-ATA/100 (also called Ultra-DMA or UDMA/100), which increases the Ultra-ATA burst transfer rate by reducing setup times and increasing the clock rate. As with ATA-5, the faster modes require the improved 80-conductor cable. Using the new ATA/100 mode requires both a drive and motherboard interface that supports that mode.

Besides adding the 100MB/sec UDMA Mode 5 transfer rate, ATA-6 also extends drive capacity greatly, and just in time. ATA-5 and earlier standards supported drives of up to only 136.9GB in capacity, which was becoming a limitation as larger drives are becoming available. At least one company has introduced 3 1/2-inch drives that are larger than that, but originally they could be released only in SCSI versions because SCSI didn't share the same limitation problems of ATA. With ATA-6, the drive limit has been expanded from (2^{28}–2^{20}) sectors to (2^{48}) sectors. What this means is that Logical Block Addressing used to use a 28-bit number, but with ATA-6 it now uses a 48-bit number instead. With 512 bytes per sector, this raises maximum supported drive capacity to 144.12PB. That is equal to more than 144.12 quadrillion bytes!

As a historical note, ATA-6 will likely be the last revision of the venerable parallel ATA standard. The future of ATA is called Serial ATA, and it is covered later in this chapter.

ATA Features

The ATA standards have gone a long way toward eliminating incompatibilities and problems with interfacing IDE drives to ISA/PCI bus systems. The ATA specifications define the signals on the 40-pin connector, the functions and timings of these signals, cable specifications, and so on. The following section lists some of the elements and functions defined by the ATA specification.

ATA I/O Connector

The ATA interface connector is normally a 40-pin header-type connector with pins spaced 0.1 inches (2.54mm) apart and generally is keyed to prevent the possibility of installing it upside down (see Figures 7.1 and 7.2). To create a keyed connector, the manufacturer generally removes pin 20 from the male connector and blocks pin 20 on the female cable connector, which prevents the user from installing the cable backward. Some cables also incorporate a protrusion on the top of the female cable connector, which fits into a notch in the shroud surrounding the mating male connector on the device. The use of keyed connectors and cables is highly recommended; plugging in an IDE cable backward normally won't cause any permanent damage. However, it can lock up the system and prevent it from running at all.

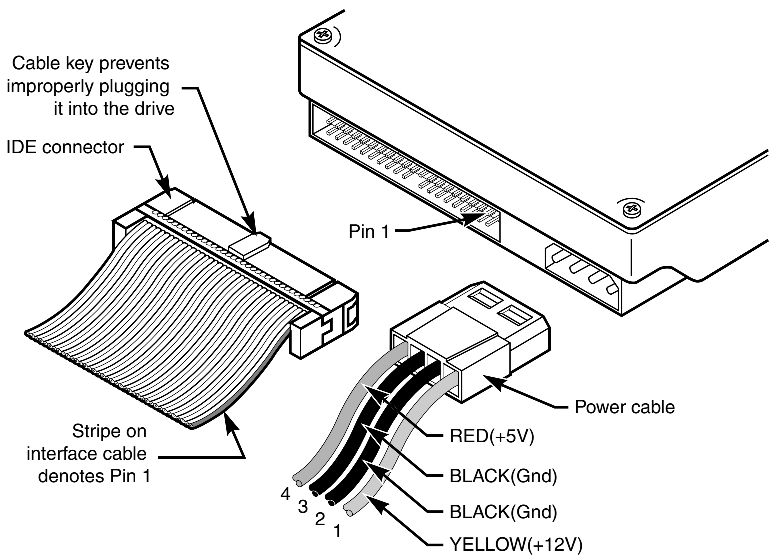

Figure 7.1 Typical ATA (IDE) hard drive connectors.

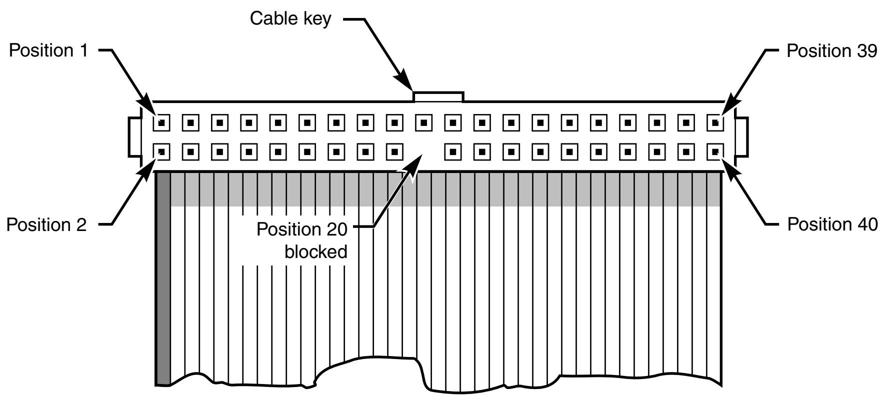

Figure 7.2 ATA (IDE) 40-pin interface connector detail.

Table 7.2 shows the standard 40-pin ATA-IDE interface connector pinout.

Table 7.2 40-Pin ATA Connector

Signal Name	Pin	Pin	Signal Name
-RESET	1	2	GROUND
Data Bit 7	3	4	Data Bit 8
Data Bit 6	5	6	Data Bit 9
Data Bit 5	7	8	Data Bit 10
Data Bit 4	9	10	Data Bit 11
Data Bit 3	11	12	Data Bit 12
Data Bit 2	13	14	Data Bit 13
Data Bit 1	15	16	Data Bit 14
Data Bit 0	17	18	Data Bit 15
GROUND	19	20	KEY (pin missing)
DRQ 3	21	22	GROUND
-IOW	23	24	GROUND
-IOR	25	26	GROUND
I/O CH RDY	27	28	CSEL:SPSYNC[1]
-DACK 3	29	30	GROUND
IRQ 14	31	32	Reserved[2]
Address Bit 1	33	34	-PDIAG
Address Bit 0	35	36	Address Bit 2
-CS1FX	37	38	-CS3FX
-DA/SP	39	40	GROUND
+5V (Logic)	41	42	+5V (Motor)
GROUND	43	44	Reserved

1. Pin 28 is normally cable select, but some older drives could use it for spindle synchronization.

2. Pin 32 was defined as -IOCS16 in ATA-2 but is no longer used.

Notebook-size, 2 1/2-inch drives normally use a smaller unitized 50-pin header connector with pins spaced only 2.0mm (0.079 inches) apart. The main 40-pin part of the connector is the same as the standard ATA connector (except for the physical pin spacing), but there are added pins for power and jumpering. Normally, the cable that plugs into this connector has 44 pins, carrying power as well as the standard ATA signals. The jumper pins normally have a jumper on them (the jumper position controls cable select, master, or slave settings). Figure 7.3 shows the unitized 50-pin connector used on 2 1/2-inch ATA drives.

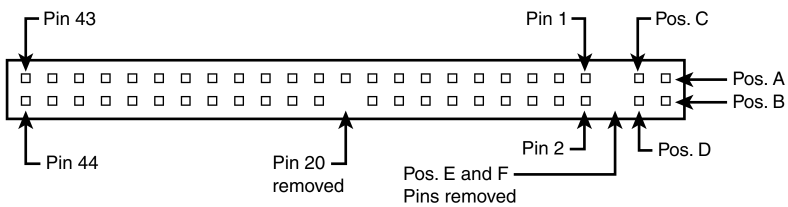

Figure 7.3 50-pin unitized ATA connector detail (used on 2 1/2-inch ATA drives).

Note the jumper pins at positions A–D and that the pins at positions E and F are removed. A jumper usually is placed between positions B and D to set the drive for cable select operation. On this connector pin 41 provides +5V power to the drive logic (circuit board), pin 42 provides +5V power to the motor (2 1/2-inch drives use 5V motors, unlike larger drives that normally use 12V motors), and pin 43 provides a power ground. The last pin (44) is reserved and not used.

Table 7.3 shows the 50-pin unitized ATA interface connector pinout as used on most 2 1/2-inch (laptop or notebook computer) drives.

Table 7.3 50-Pin Unitized ATA Connector Pinout

Signal Name	Pin	Pin	Signal Name
Jumper pin	A	B	Jumper pin
Jumper pin	C	D	Jumper pin
KEY (pin missing)	E	F	KEY (pin missing)
-RESET	1	2	GROUND
Data Bit 7	3	4	Data Bit 8
Data Bit 6	5	6	Data Bit 9
Data Bit 5	7	8	Data Bit 10

GROUND	43	44	Reserved

Not All Cables and Connectors Are Keyed

Note that many lower-cost board and cable manufacturers leave out the keying. Cheaper motherboards often won't have pin 20 removed on their IDE connectors, and consequently they won't supply a cable with pin 20 blocked. If they don't use a shrouded connector with a notch and a corresponding protrusion on the cable connector, no keying exists and the cables can be inserted backward. Fortunately, the only consequence of this in most cases is that the device won't work until the cable is attached with the correct orientation.

In rare situations in which you are mixing and matching items, you might encounter a cable with pin 20 blocked (as it should be) and a board with pin 20 still present. In that case, you can break off pin 20 from the board, or for the more squeamish, remove the block from the cable. Some cables have the block permanently installed as a part of the connector housing, in which case you must break off pin 20 on the board or device end or use a different cable.

The simple rule of thumb is that pin 1 should be oriented toward the power connector on the device, which normally corresponds to the stripe on the cable.

ATA I/O Cable

A 40-conductor ribbon cable is specified to carry signals between the bus adapter circuits and the drive (controller). To maximize signal integrity and eliminate potential timing and noise problems, the cable should not be longer than 18 inches (0.46 meters).

Note that ATA drives supporting the higher-speed transfer modes, such as PIO Mode 4 or any of the Ultra-DMA (UDMA) modes, are especially susceptible to cable integrity problems and cables that are too long. If the cable is too long, you can experience data corruption and other errors that can be maddening. This will be manifested in any type of problem reading from or writing to the drive. In addition, any drive using UDMA Mode 4 (66MB/sec transfer rate) or Mode 5 (100MB/sec transfer rate) must use a special higher-quality 80-conductor cable (the extra conductors are grounds to reduce noise). I also recommend this type of cable if your drive is running at UDMA Mode 2 (33MB/sec) or slower because it can't hurt and can only help. I always keep a high-quality 80-conductor IDE cable in my toolbox for testing drives where I suspect cable integrity or cable length problems. Figure 7.4 shows the typical ATA cable layout and dimensions.

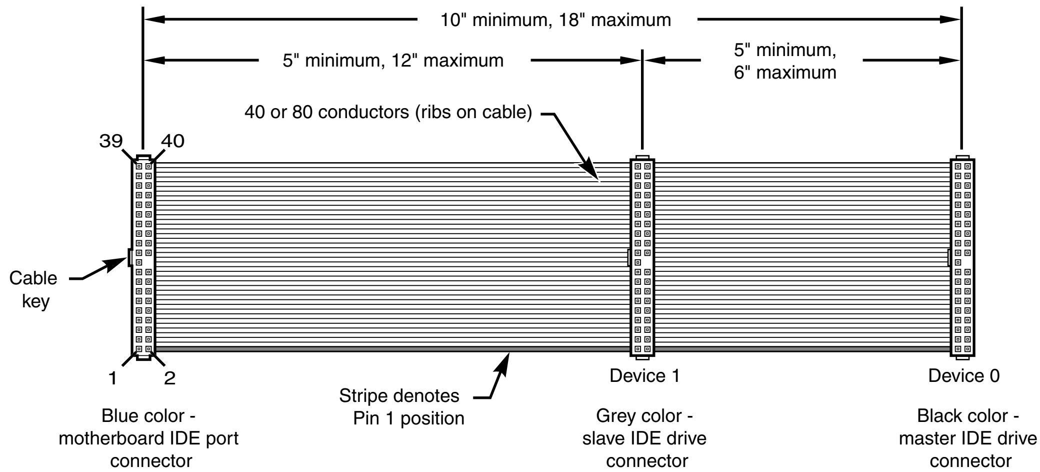

Figure 7.4 ATA (IDE) cable, with 40-pin connectors and either 40- or 80-conductor cables (additional wires are grounded in 80-conductor versions).

Note

Most 40-conductor cables do not color-code the connectors, whereas all 80-conductor cables do color-code the connectors.

Two primary variations of IDE cables are used today: one with 40 conductors and the other with 80 conductors. Both use 40-pin connectors, and the additional wires in the 80-conductor version are simply wired to ground. The additional conductors are designed to reduce noise and interference and are required when setting the interface to run at 66MB/sec (ATA/66) or faster. The drive and host adapter are designed to disable the higher-speed ATA/66 or ATA/100 modes if an 80-conductor cable is not detected. The 80-conductor cable can also be used at lower speeds; although this is unnecessary, it improves the signal integrity. Therefore, it is the recommended version no matter which drive you use.

Note the keying on the cable that is designed to prevent backward installation.

ATA Signals

This section describes some of the most important signals in more detail.

Pin 20 is used as a key pin for cable orientation and is not connected to the interface. This pin should be missing from any ATA connectors, and the cable should have the pin-20 hole in the connector plugged off to prevent the cable from being plugged in backward.

Pin 39 carries the drive active/slave present (DASP) signal, which is a dual-purpose, time-multiplexed signal. During power-on initialization, this signal indicates whether a slave drive is present on the interface. After that, each drive asserts the signal to indicate that it is active. Early drives could not multiplex these functions and required special jumper settings to work with other drives. Standardizing this function to allow for compatible dual-drive installations is one of the features of the ATA standard. This is why some drives require a slave present (SP) jumper, whereas others do not.

Pin 28 carries the cable select signal (CSEL). In some older drives, it could also carry a spindle synchronization signal (SPSYNC), but that is not commonly found on newer drives. The CSEL function is the most widely used and is designed to control the designation of a drive as master (drive 0) or slave (drive 1) without requiring jumper settings on the drives. If a drive sees the CSEL as being grounded, the drive is a master; if CSEL is open, the drive is a slave.

You can install special cabling to ground CSEL selectively. This installation usually is accomplished through a Y-cable arrangement, with the IDE bus connector in the middle and each drive at opposite ends of the cable. One leg of the Y has the CSEL line connected through, indicating a master drive; the other leg has the CSEL line open (conductor interrupted or removed), making the drive at that end the slave.

Dual-Drive Configurations

Dual-drive ATA installations can be problematic because each drive has its own controller and both controllers must function while being connected to the same bus. There has to be a way to ensure that only one of the two controllers will respond to a command at a time.

The ATA standard provides the option of operating on the AT bus with two drives in a daisy-chained configuration. The primary drive (drive 0) is called the master, and the secondary drive (drive 1) is called the slave. You designate a drive as being master or slave by setting a jumper or switch on the drive or by using a special line in the interface called the cable select pin and setting the CS jumper on the drive.

When only one drive is installed, the controller responds to all commands from the system. When two drives (and, therefore, two controllers) are installed, both controllers receive all commands from the system. Each controller then must be set up to respond only to commands for itself. In this situation, one controller must be designated as the master and the other as the slave. When the system sends a command for a specific drive, the controller on the other drive must remain silent while the selected controller and drive are functioning. Setting the jumper to master or slave enables discrimination between the two controllers by setting a special bit (the DRV bit) in the Drive/Head Register of a command block.

Configuring IDE drives can be simple, as is the case with most single-drive installations, or troublesome, especially when it comes to mixing two drives from different manufacturers on a single cable.

Most IDE drives can be configured with four possible settings:

- Master (single-drive)
- Master (dual-drive)
- Slave (dual-drive)
- Cable select

Some drives simplify this to three settings: master, slave, and cable select. Because each IDE drive has its own controller, you must specifically tell one drive to be the master and the other to be the slave. No functional difference exists between the two, except that the drive that's specified as the slave will assert a signal called DASP after a system reset informs the master that a slave drive is present in the system. The master drive then pays attention to the drive select line, which it otherwise ignores. Telling a drive that it's the slave also usually causes it to delay its spinup for several seconds to allow the master to get going and thus to lessen the load on the system's power supply.

Until the ATA IDE specification, no common implementation for drive configuration was in use. Some drive companies even used different master/slave methods for different models of drives. Because of these incompatibilities, some drives work together only in a specific master/slave or slave/master order. This situation mostly affects older IDE drives introduced before the ATA specification.

Most drives that fully follow the ATA specification now need only one jumper (master/slave) for configuration. A few also need a slave present jumper, as well. Table 7.4 shows the jumper settings required by most ATA IDE drives.

Table 7.4 Jumper Settings for Most ATA IDE-Compatible Drives on Standard (Non–Cable Select) Cables

Jumper Name	Single-Drive	Dual-Drive Master	Dual-Drive Slave
Master (M/S)	On	On	Off
Slave Present (SP)	Off	On	Off
Cable Select (CS)	Off	Off	Off

Note

If a cable select cable is used, the CS jumper should be set On and all others should be Off. The cable connector then determines which drive will be master or slave.

Figure 7.5 shows the jumpers on a typical ATA drive.

The master jumper indicates that the drive is a master or a slave. Some drives also require a slave present jumper, which is used only in a dual-drive setup and then installed only on the master drive—which is somewhat confusing. This jumper tells the master that a slave drive is attached. With many ATA IDE drives, the master jumper is optional and can be left off. Installing this jumper doesn't hurt in these cases and can eliminate confusion; I recommend that you install the jumpers listed here.

Note

Note that some drives have these jumpers on the drive circuit board, and as such they might not be visible on the rear.

To eliminate confusion over master/slave settings, most newer systems now use the cable select option. This involves two things. The first is having a special IDE cable that has all the wires except pin 28 running from the motherboard connector to both drive connectors. Pin 28 is used for cable select and is connected to one of the drive connectors (labeled master) and not to the other (labeled slave). Both drives are then configured in cable select mode via the CS jumper on each drive.

With cable select, the drive that receives signals on pin 28 automatically becomes the master, and the other becomes the slave. Most cables implement this by removing the metal insulation displacement bit from the pin-28 hole, which can be difficult to see at a glance. Other cables have a section of pin 28 visibly cut from the cable somewhere along the ribbon. Because this is such a minor modification to the cable and can be difficult to see, cable select cables normally have the connectors labeled master, slave, and system, indicating that the cable controls these options rather than the drive. All 80-conductor UltraATA cables are designed to use cable select.

With cable select, you simply set the CS jumper on all drives and then plug the drive you want to be the master into the connector labeled master on the cable and the drive you want to be the slave into the connector labeled slave.

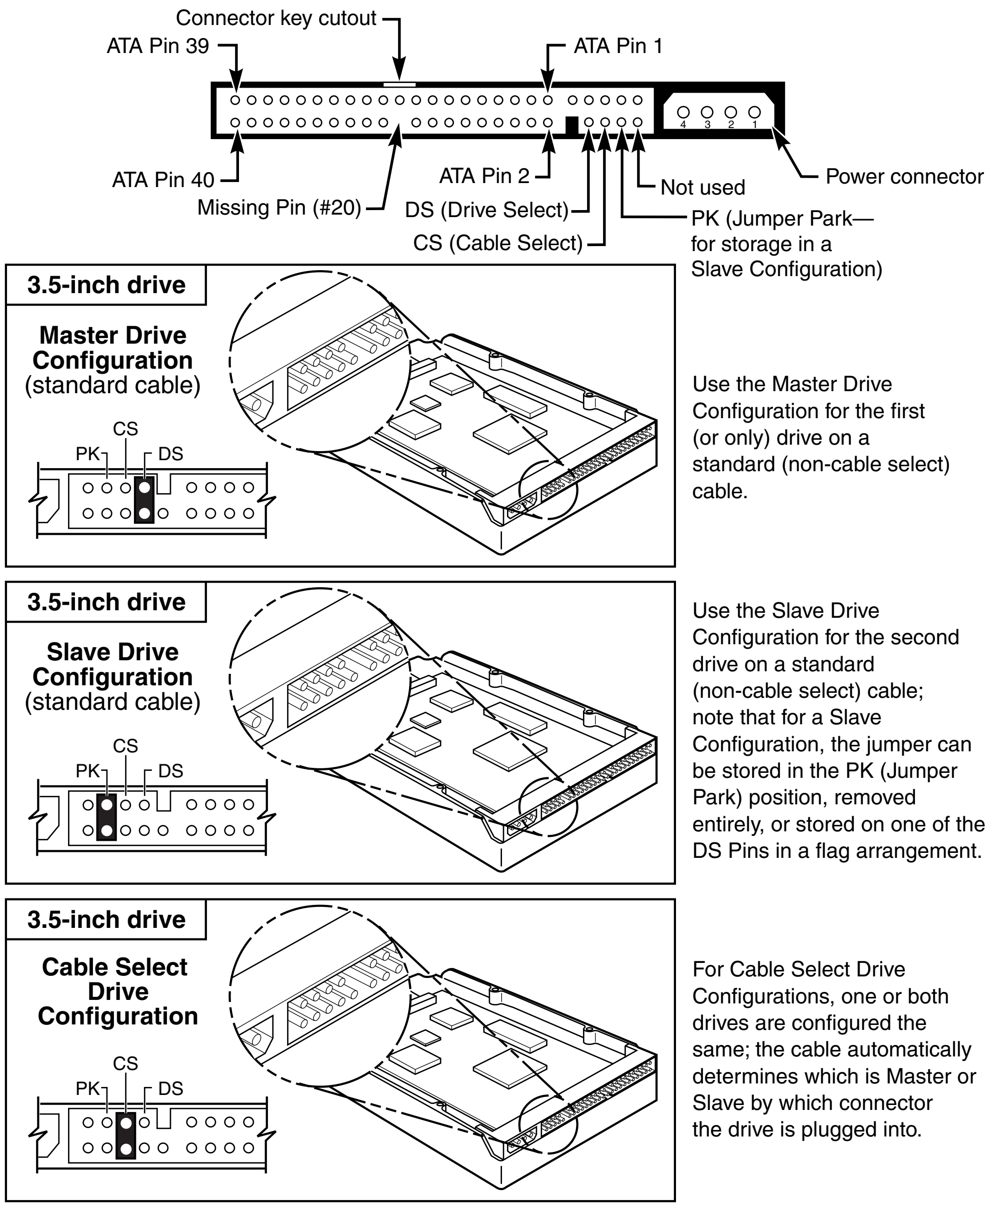

Figure 7.5 ATA (IDE) drive jumpers for most drives. Note that the drive is shown upside down in this figure, whereas previous figures in this chapter depict drives as they appear right side up.

ATA Commands

One of the best features of the ATA IDE interface is the enhanced command set. The ATA IDE interface was modeled after the WD1003 controller IBM used in the original AT system. All ATA IDE drives must support the original WD command set (eight commands) with no exceptions, which is why IDE drives are so easy to install in systems today. All IBM-compatible systems have built-in ROM BIOS support for the WD1003, so they essentially support ATA IDE as well.

In addition to supporting all the WD1003 commands, the ATA specification added numerous other commands to enhance performance and capabilities. These commands are an optional part of the ATA interface, but several of them are used in most drives available today and are very important to the performance and use of ATA drives in general.

Perhaps the most important is the Identify Drive command. This command causes the drive to transmit a 512-byte block of data that provides all details about the drive. Through this command, any program (including the system BIOS) can find out exactly which type of drive is connected, including the drive manufacturer, model number, operating parameters, and even the serial number of the drive. Many modern BIOSes use this information to automatically receive and enter the drive's parameters into CMOS memory, eliminating the need for the user to enter these parameters manually during system configuration. This arrangement helps prevent mistakes that can later lead to data loss when the user no longer remembers what parameters he used during setup.

The Identify Drive data can tell you many things about your drive, including the following:

- Number of cylinders in the recommended (default) translation mode
- Number of heads in the recommended (default) translation mode
- Number of sectors per track in the recommended (default) translation mode
- Number of cylinders in the current translation mode
- Number of heads in the current translation mode
- Number of sectors per track in the current translation mode
- Manufacturer and model number
- Firmware revision
- Serial number
- Buffer type, indicating sector buffering or caching capabilities

Several public-domain programs can execute this command to the drive and report the information onscreen. I use the IDEINFO (available at `http://www.dc.ee/Files/Utils/IDEINFO.ARJ`) or IDEDIAG (available from many of the popular shareware sites) program. I find these programs especially useful when I am trying to install IDE drives and need to know the correct parameters for a user-definable BIOS type. These programs get the information directly from the drive.

Two other important commands are the Read Multiple and Write Multiple commands. These commands permit multiple-sector data transfers and, when combined with block-mode PIO capabilities in the system, can result in incredible data-transfer rates many times faster than single-sector PIO transfers.

MMMany other enhanced commands are available, including room for a given drive manufacturer to implement what are called vendor-unique commands. These commands often are used by a particular vendor for features unique to that vendor. Often, features such as low-level formatting and defect management are controlled by vendor-unique commands. This is why low-level format programs can be so specific to a particular manufacturer's IDE drives and why many manufacturers make their own LLF programs available.

ATA Upgrades

Since ATA-1, newer versions of the ATA interface and complementary BIOS support larger and faster drives, as well as different types of devices other than hard disks. This section details these areas of improvement.

ATA-2 through ATA-6 have improved the original ATA/IDE interface in four main areas:

- Secondary two-device channel
- Increased maximum drive capacity
- Faster data transfer
- ATAPI (ATA Program Interface)

The following sections describe these improvements.

Secondary ATA Channel

Although even ATA-1 was never limited to a single channel, systems at that time normally had only a primary channel built into the motherboard. Starting when the ATA-2 standard was published, most systems began including a second ATA interface, called the secondary channel. Because each channel could support two drives, this allowed for up to four devices to be installed.

If more than four ATA devices are needed, you can install additional ATA ports via add-on cards, which normally plug into PCI slots. These additional ports are not supported directly by the motherboard BIOS, but the card can have an adapter BIOS that will be recognized at boot time. Even without an onboard BIOS, devices attached to the card can be supported by drivers—the only feature lacking without ROM-based support is that the capability to be directly bootable.

Companies such as Promise Technologies, MicroFirmware, GSI, and others make add-on ATA adapters that allow using more than the two ports that come built into most motherboards.

Drive Capacity Limitations

ATA interface versions up through ATA-5 suffered from a drive capacity limitation of 136.9GB (billion bytes). Depending on the BIOS used, this limitation can be further reduced to 8.4GB, or even as low as 528MB (million bytes). This is due to limitations in both the BIOS and the ATA interface, which when combined create even further limitations. To understand these limits, you have to look at the BIOS and ATA interface.

The pertinent limitations are those of the ATA interface itself as well as the BIOS (drivers) used to talk to the interface. A summary of the limitations are shown in Table 7.5.

Table 7.5 ATA/IDE Drive Capacity Limitations

Specification	Maximum Sectors	Capacity[1]	Maximum Capacity
ATA-5 interface	267,386,880	136,902,082,560	136.9GB
Standard CHS BIOS	1,032,192	528,482,304	528.5MB
CHS BIOS with translation	16,515,072	8,455,716,864	8.4GB
Enhanced (EDD BIOS)	18,446,744,073,709,551,600	9,444,732,965,739,290,430,000	9.4ZB

1. Maximum capacity in bytes
ATA = AT Attachment
CHS = cylinder head sector
EDD = enhanced disk drive
MB = million bytes
GB = billion bytes
ZB = zettabytes, one ZB equals one billion trillion bytes

This section explores these limitations in more detail.

The BIOS-based driver for hard disks is accessed via software interrupt 13h (13 hex), which offers functions for reading and writing drives at the sector level. INT13h requires that the particular sector be addressed by its cylinder, head, and sector location, otherwise known as *CHS addressing*. This interface is used by the operating system and low-level disk utilities to access the drive. The INT13h interface originally was written by IBM for the BIOS on the PC XT hard disk controller in 1983 and then incorporated into the AT motherboard BIOS in 1984. This interface used numbers to define the particular cylinder, head, and sector being addressed. Table 7.6, which shows the standard INT13h BIOS CHS parameter limits, includes the maximum values for these numbers.

Table 7.6 INT13h BIOS CHS Parameter Limits

Field	Field Size	Maximum Value	Range	Total Usable
Cylinder	10 bits	1,024	0–1023	1,024
Head	8 bits	256	0–255	256
Sector	6 bits	64	1–63	63

The concept is simple: If you had a hotel with two-digit decimal numbers, you could have only 100 rooms, numbered 0–99. CHS numbers used by the BIOS INT13h interface are binary, and with a 10-bit number being used for cylinders, you can have only 1,024 maximum, numbered 0–1023. Because the head you want to access is identified by an 8-bit number, the maximum number of heads the BIOS could handle is 256, numbered 0–255. Finally, with sectors there is a minor difference. Sectors on a track are identified by a 6-bit number, which would normally allow a maximum of 64; because sectors are numbered starting with 1 (instead of 0), however, the range is limited to 1–63, which means a total of 63 sectors per track is the maximum the BIOS can handle.

These BIOS limitations are true for all BIOS versions or programs that rely on standard CHS addressing, using the INT13h BIOS interface. Using the maximum numbers possible for CHS, a drive with 1,024 cylinders, 256 heads, and 63 sectors per track is possible. Because each sector is 512 bytes, the math works out as follows:

```
                Max. Values
---------------------------
    Cylinders        1,024
        Heads          256
```

```
Sectors/Track           63
==========================
Total Sectors   16,515,072
--------------------------
Total Bytes  8,455,716,864
Megabytes (MB)       8,456
Mebibytes (MiB)      8,064
Gigabytes (GB)         8.4
Gibibytes (GiB)        7.8
```

From these calculations, you can see that the maximum size drive addressable via the BIOS INT13h interface is about 8.4GB (where GB equals roughly one billion bytes), or 7.8GiB (where GiB means *gigabinarybytes*).

Note that the Gi (gigabinary) designation is a standard designed to eliminate confusion between decimal- and binary-based multiples, especially in computer systems. In December 1998, the International Electrotechnical Commission (IEC) approved as an international standard the prefix names and symbols for binary multiples used in data processing and transmission. The prefixes are shown in Table 7.7.

Table 7.7 Standard Prefix Names and Symbols for Binary Multiples

		Decimal Prefixes	
Factor	**Symbol**	**Name**	**Value**
10^3	K	Kilo	1,000
10^6	M	Mega	1,000,000
10^9	G	Giga	1,000,000,000
10^{12}	T	Tera	1,000,000,000,000
10^{15}	P	Peta	1,000,000,000,000,000

		Binary Prefixes		
Factor	**Symbol**	**Name**	**Derivation**	**Value**
2^{10}	Ki	Kibi	Kilobinary	1,024
2^{20}	Mi	Mebi	Megabinary	1,048,576
2^{30}	Gi	Gibi	Gigabinary	1,073,741,824
2^{40}	Ti	Tebi	Terabinary	1,099,511,627,776
2^{50}	Pi	Pebi	Petabinary	1,125,899,906,842,624

Note

Under this standard terminology, an MB (megabyte) would be 1,000,000 bytes, whereas an MiB (mebibyte) would be 1,048,576 bytes.

Another way of looking at this is that each sector can be addressed using a single 24-bit number (10 bits plus 8 bits plus 6 bits). Because the 6-bit portion cannot be all 0s, the total number of sectors addressable would be defined as $2^{24} – 2^{18}$, or 16,777,216 – 262,144 = 16,515,072 sectors. Because each sector is 512 bytes, the maximum capacity supported by the BIOS is 8.4GB.

Unfortunately for ATA, the BIOS limits are not the only limitations that apply. Limits also exist in the ATA interface itself. The ATA limits are shown in Table 7.8.

Table 7.8 Standard ATA Parameter Limitations

Field	Field Size	Maximum Value	Range	Total Usable
Cylinder	16 bits	65536	0–65535	65536
Head	4 bits	16	0–15	16
Sector	8 bits	256	1–255	255

As you can see, the ATA limits are higher than the BIOS limits for cylinders and sectors but lower than the BIOS limits for heads. The total limits for capacity according to the ATA specifications are as follows:

```
                  Max. Values
-----------------------------
    Cylinders          65,536
        Heads              16
Sectors/Track             255
=============================
Total Sectors     267,386,880
-----------------------------
Total Bytes   136,902,082,560
Megabytes (MB)        136,902
Mebibytes (MiB)       130,560
Gigabytes (GB)          136.9
Gibibytes (GiB)         127.5
```

Note that the ATA limitations also can be expressed as a single 28-bit number—the 16-bit cylinder number plus the 4-bit head number plus the 8-bit sector number. To maintain compatibility between LBA and CHS modes in which the sector number must start from 1 instead of 0, the maximum capacity is $2^{28} - 2^{20}$, or 268,435,456 – 1,048,576 = 267,386,880 sectors. Because each sector is 512 bytes, the maximum capacity supported by ATA through ATA-5 is 136.9GB.

ATA-6 increases this limit substantially by going to an LBA interface that uses 48-bit sector addressing. This means that maximum capacity is increased to 2^{48} sectors. This is equal to 281,474,976,710,656 total sectors. Because each sector stores 512 bytes, this results in a maximum drive capacity of

```
                           Max. Values
--------------------------------------
Total Sectors      281,474,976,710,656
--------------------------------------
Total Bytes    144,115,188,075,855,888
Megabytes (MB)         144,115,188,076
Mebibytes (MiB)        137,438,953,472
Gigabytes (GB)             144,115,188
Gibibytes (GiB)            134,217,728
Terabytes (TB)                 144,115
Tebibytes (TiB)                131,072
Petabytes (PB)                     144
Pebibytes (PiB)                    128
```

This allows a capacity of just over 144PB (petabytes = quadrillion bytes)! It should be awhile before you have to worry about that barrier being broken.

When you combine the limitations of the BIOS and ATA interface, you end up with the situation as shown in Table 7.9.

Table 7.9 Combined CHS BIOS and ATA Parameter Limits

Field	CHS BIOS Parameter Limits	ATA Parameter Limits	Combined Limits
Cylinder	1,024	65,536	1,024
Head	256	16	16
Sector	63	255	63
Total Sectors	16,515,072	267,386,880	1,032,192
Maximum Capacity	8.4GB	136.9GB	528MB

As you can see, combining these limits results in maximum usable parameters of 1,024 cylinders, 16 heads, and 63 sectors, which results in a maximum drive capacity of 528MB.

Starting in 1993–94, most BIOSes began implementing a fix for these problems, which enabled drives up to the BIOS limit of 8.4GB to be used. This fix involved what is termed *parameter translation* at the BIOS Setup level, which adapted or translated the cylinder, head, and sector numbers to fit within the allowable BIOS parameters. There are two types of translation: One works mathematically off the reported CHS parameters (called Large or Extended CHS in the BIOS Setup); the other is derived from the total number of sectors (called Logical Block Address or LBA in the BIOS Setup). Both translation schemes result in the same thing; they just use two different mathematical algorithms to get there. Due to some limitations with the CHS translations, you usually should select LBA translation if that is an option in your BIOS setup.

Virtually all PC BIOSes since 1994 have translation capability in the BIOS Setup, and virtually all offer both CHS translation as well as LBA translation modes. If both translation modes are offered, you should choose the LBA method of translation because it is the more efficient of the two. Both normally result in the same translated CHS parameters; however, depending on the specific drive parameters reported, the geometries can vary depending on the translation method selected. If you were to set up and format a drive using CHS translation and then change to LBA translation, the interpreted geometry could change and the drive could then become unreadable. Bottom line: After you select a translation method, don't plan on changing it unless you have your data securely backed up.

With translation, the parameters reported by the drive are translated. The physical parameters reported by the drive are modified into parameters that are acceptable to the BIOS. Here is an example:

```
                     Physical      Logical
                          CHS          CHS
                   Parameters   Parameters
------------------------------------------
        Cylinders      12,000          750
            Heads          16          256
    Sectors/Track          63           63
==========================================
    Total Sectors  12,096,000   12,096,000
     Capacity (MB)      6,193        6,193
   Capacity (Meg)       5,906        5,906
```

This example shows a drive with 12,000 cylinders and 16 heads. The physical cylinder count is way above the BIOS limit of 1,024, so in translating the BIOS Setup divides the cylinder count by 2, 4, 8, or 16 to bring it down below 1,024. In this case it was necessary to divide by 16, which results in a new cylinder count of 750—well below the 1,024 maximum. Because the cylinder count was divided by 16, the head count is then multiplied by the same number, resulting in 256 heads, which is right at the limit the BIOS can handle. So, although the drive physically has 12,000 cylinders and 16 heads, the BIOS and all software (including the operating system) instead see the drive as having 750 cylinders and 256 heads. Note that the 63 sector count is simply carried over without change. The result is that by using the new parameters the BIOS can see the entire 6GB drive and won't be limited to just the first 528MB.

When you install a drive, you don't have to do the translation math; the BIOS Setup does that for you behind the scenes. All you have to do is either allow the BIOS to autodetect the drive physical parameters and enable ECHS (large) or LBA translation. The BIOS Setup does the rest of the work for you.

You usually can tell whether your BIOS supports translation by the capability to specify more than 1,024 cylinders in the BIOS Setup, although this can be misleading. The best clue is to look for the translation setting parameters in the IDE drive setup page in the BIOS Setup. See Chapter 5, "BIOS," for more information on how to enter the BIOS Setup on your system. If you see drive-related settings, such as LBA or ECHS (sometimes called Large or Extended), these are telltale signs of a BIOS with translation support. Most BIOSes with a date of 1994 or later include this capability. If your system currently does not support parameter translation, you might be able to get an upgrade from your motherboard manufacturer or install a BIOS upgrade card with this capability such as the ATA Pro Flash by MicroFirmware (see the Vendor List on the CD included with this book).

Table 7.10 shows the four ways today's BIOSes can handle addressing sectors on the drive: Standard CHS (no translation), Extended CHS translation, LBA translation, and pure LBA addressing. They are summarized in the following table.

Table 7.10 Drive Sector Addressing Methods

BIOS Mode	Operating System to BIOS	BIOS to Drive
Standard (normal) No translation	Physical CHS Parameters	Physical CHS Parameters
Extended CHS (large) Translation	Logical CHS Parameters	Physical CHS Parameters
LBA Translation	Logical CHS Parameters	LBA Parameters
Pure LBA (EDD BIOS)	LBA Parameters	LBA Parameters

In Standard CHS, there is only one possible translation step internal to the drive. The drive's actual physical geometry is completely invisible from the outside with all zoned recorded ATA drives today. The cylinders, heads, and sectors printed on the label for use in the BIOS setup are purely logical geometry and do not represent the actual physical parameters. Standard CHS addressing is limited to 16 heads and 1,024 cylinders, which provides a limit of 504MB.

This is often called "Normal" in the BIOS setup and causes the BIOS to behave like an old-fashioned one without translation. Use this setting if your drive has fewer than 1,024 cylinders or if you want to use the drive with a non-DOS operating system that doesn't understand translation.

In Extended CHS, a translated logical geometry is used to communicate between the drive and the BIOS, whereas a different translated geometry is used to communicate between the BIOS and everything else. In other words, normally two translation steps exist. The drive still translates internally but has logical parameters that exceed the 1,024-cylinder limitation of the standard BIOS. In this case, the drive's cylinder count is usually divided by 2, and the head count is multiplied by 2 to get the translated values from those actually stored in the CMOS Setup. This type of setting breaks the 504MB/528MB barrier.

This often is called "Large" or "ECHS" in the BIOS setup and tells the BIOS to use Extended CHS translation. It uses a different geometry (cylinders/heads/sectors) when talking to the drive than when talking to the BIOS. This type of translation should be used with drives that have more than 1,024 cylinders but that do not support LBA. Note that the geometry entered in your BIOS Setup is the logical geometry, not the translated one.

LBA is a means of linearly addressing sector addresses, beginning at Cylinder 0, Head 0, Sector 1 as LBA 0, and proceeding on to the last physical sector on the drive. This is new in ATA-2 but has always been the one-and-only addressing mode in SCSI.

With LBA, each sector on the drive is numbered starting from 0. The number is a 28-bit binary number internally, which translates to a sector number from 0 to 267,386,879. Because each sector represents 512 bytes, this results in a maximum drive capacity of exactly 136.9GB. Unfortunately, the operating system still needs to see a translated CHS, so the BIOS determines how many sectors there are and comes up with Translated CHS to match. The BIOS CHS limits are 1,024 cylinders, 256 heads, and 63 sectors per track, which limits total drive capacity to 8.4GB.

In other words, this scheme breaks the 528MB barrier in essentially the same way as Extended CHS does. Because it is somewhat simpler to use a single linear number to address a sector on the hard disk compared to a CHS type address, LBA translation is the preferred method if the drive supports it.

Caution

A word of warning with these BIOS translation settings: If you switch between Standard CHS, Extended CHS, or LBA, the BIOS can change the (translated) geometry. This usually occurs only if the number of sectors reported by the Identify Drive command is fewer than 63 because LBA translations result in 63 sectors per track. The same thing can happen if you transfer a disk that has been formatted on an old, non-LBA computer to a new one that uses LBA. This causes the logical CHS geometry seen by the operating system to change and the data to appear in the wrong locations from where it actually is! This can cause you to lose access to your data if you are not careful. I always recommend recording the CMOS Setup screens associated with the hard disk configuration so you can properly match the setup of a drive to the settings to which it was originally set.

Breaking the 8.4GB Barrier

Systems using ATA drives have been plagued by size limitations because of ATA interface and BIOS issues. The first two limits were mostly BIOS related; the first was at 528MB and the second at 8.4GB using parameter translation.

Unfortunately, translating parameters works only within the limitations of the BIOS, which means that, although translation breaks the 528MB barrier, it runs into another barrier at 8.4GB. Therefore, translation is still limited by the BIOS maximum of 8.4GB support.

Supporting drives larger than that requires a whole new addressing scheme, which no longer uses the clumsy CHS numbers and instead uses only the LBA or sector number directly. Phoenix Technologies recognized this problem early on and, beginning in 1994, began publishing a document titled "BIOS Enhanced Disk Drive Specification," which addressed this problem with an elegant solution. Their idea in publishing was to get the other BIOS manufacturers to follow their lead so all the BIOSes would be compatible with each other.

To ensure further development and compatibility, after several revisions in 1996, Phoenix turned this document over to the National Committee on Information Technology Standards (NCITS) for further enhancement and certification as a standard called the "BIOS Enhanced Disk Drive Specification (EDD)." Starting in 1998, most of the other BIOS manufacturers began installing EDD support in their BIOSes, finally enabling support for ATA drives larger than 8.4GB. Coincidentally (or not), this support arrived just in time because ATA drives of that size and larger became available that year.

The EDD document describes new services provided by the BIOS to support storage devices of up to 2^{64} sectors, which results in a capacity of more than 9.44ZB (a zettabyte equals a trillion GB: 9.44×10^{21} or, to be more precise, 9,444,732,965,739,290,430,000 bytes!). Older BIOS services have a compatibility limit of 528MB and a theoretical limit of 8.4GB. Starting in mid-1998, most systems incorporated the enhanced BIOS services. Note that even though the BIOS can handle drives with up to 2^{64} sectors, an ATA drive is still currently limited in size to 2^{48} sectors, or 144,115,188GB (144PB) maximum.

According to this EDD specification, drives are accessed by the pure LBA number without any CHS translation, while still preserving limited backward compatibility with CHS for the first 8.4GB of the drive. EDD has support for up to 2^{64} total sectors. This works out to a drive capacity as shown in the following calculations:

$2^{64} = 1.8446744073709551 6\times10^{19}$ sectors

$= 9.44473296573929043\times10^{21}$ bytes

= 9.4 giga-tera (billion trillion) bytes!

Phoenix originally claimed that the EDD specification would hold us for another 15 years. However, at the rate of growth where drive capacity doubles every 1.5–2 years (Moore's Law), considering that 180GB ATA drives were available in 2001, this standard should take us at least through the year 2055, and possibly as far as the year 2073 before we need a new address scheme with more bits.

If your system BIOS dates to 1998 or later, you most likely have EDD support, which means support for drives as large as 136.9GB.

With the ATA-6 specification in 2001, a new 48-bit address scheme has been designed that extends the limits to 2^{48} sectors, which is 144.12PB (petabytes). Because the BIOS services allow up to 2^{64} sectors, the 144 petabyte limitation will be the lower of the two that will apply. Still, that should hold us for some time to come.

Note that if you use older software including utilities, applications, or even operating systems that rely exclusively on CHS parameters, they will see all drives over 8.4GB as 8.4GB only. You will need not only a newer BIOS, but also newer software designed to handle the direct LBA addressing to work with drives over 8.4GB.

Operating systems limitations with respect to drives over 8.4GB are shown in Table 7.11.

Table 7.11 Operating Systems Limitations

Operating System	Limitations for Hard Drive Size
DOS/Windows 3x	DOS 6.22 or lower cannot support drives greater than 8.4GB. DOS 7.0 or higher (included with Windows 95 or later) is required to recognize a drive over 8.4GB.
Windows 9X/Me	Windows 95a (original version) does support the INT13h extensions, which means it does support drives over 8.4GB; however, due to limitations of the FAT16 file system, the maximum individual partition size is limited to 2GB. Windows 95B / OSR2 or later (including Windows 98/Me) supports the INT13h extensions, which allows drives over 8.4GB, and also supports FAT32, which allows partition sizes up to the maximum capacity of the drive.

Table 7.11 Continued

Operating System	Limitations for Hard Drive Size
Windows NT	Windows NT 3.5x does not support drives greater than 8.4GB. Windows NT 4.0 does support drivers greater than 8.4GB; however, when a drive larger than 8.4GB is being used as the primary bootable device, Windows NT will not recognize more than 8.4GB. Microsoft has released Service Pack 4, which corrects this problem.
Windows 2000/XP	Windows 2000/XP supports drives greater than 8.4GB.
OS/2 Warp	Some versions of OS/2 are limited to a boot partition size of 3.1GB or 4.3GB. IBM has a Device Driver Pack upgrade that enables the boot partition to be as large as 8.4GB. The HPFS file system in OS/2 will support drives up to 64GB.
Novell	NetWare 5.0 or later supports drives greater than 8.4GB.

Faster Data Transfer

ATA-2/EIDE and ATA-3 define several high-performance modes for transferring data to and from the drive. These faster modes are the main part of the new specifications and were the main reason they were initially developed. The following section discusses these modes.

The PIO mode determines how fast data is transferred to and from the drive. In the slowest possible mode—PIO mode 0—the data cycle time cannot exceed 600 nanoseconds (ns). In a single cycle, 16 bits are transferred into or out of the drive, making the theoretical transfer rate of PIO Mode 0 (600ns cycle time) 3.3MB/sec. Most of the high-performance ATA-2 (EIDE) drives today support PIO Mode 4, which offers a 16.6MB/sec transfer rate.

Table 7.12 shows the PIO modes, with their respective transfer rates.

Table 7.12 PIO (Programmed I/O) Modes and Transfer Rates

PIO Mode	Bus Width (bits)	Cycle Speed (ns)	Bus Speed (MHz)	Cycles per Clock	Transfer Rate (MB/sec)	ATA Specification
0	16	600	1.67	1	3.33	ATA-1
1	16	383	2.61	1	5.22	ATA-1
2	16	240	4.17	1	8.33	ATA-1
3	16	180	5.56	1	11.11	ATA-2
4	16	120	8.33	1	16.67	ATA-2

ATA-2 was also referred to as EIDE (Enhanced IDE) or Fast-ATA

ns = nanoseconds (billionths of a second)

MB = million bytes

To run in Mode 3 or 4 requires that the IDE port on the system be a local bus port. This means that it must operate through either a VL-Bus or PCI bus connection. Most motherboards with ATA-2/EIDE support have dual IDE connectors on the motherboard, and most of them now allow full throughput. Most of the motherboard chipsets include the ATA interface in their South Bridge components, which in modern systems is tied into the PCI bus.

Older 486 and some early Pentium boards have only the primary connector running through the system's PCI local bus. The secondary connector on those boards usually runs through the ISA bus and therefore supports up to Mode 2 operation only.

When interrogated with an Identify Drive command, a hard disk returns, among other things, information about the PIO and DMA modes it is capable of using. Most enhanced BIOSes automatically set the correct mode to match the capabilities of the drive. If you set a mode faster than the drive can handle, data corruption results.

ATA-2 and newer drives also perform Block Mode PIO, which means they use the Read/Write Multiple commands that greatly reduce the number of interrupts sent to the host processor. This lowers the overhead, and the resulting transfers are even faster.

DMA Transfer Modes

ATA drives also support *Direct Memory Access (DMA)* transfers. DMA means that the data is transferred directly between drive and memory without using the CPU as an intermediary, as opposed to PIO. This has the effect of offloading much of the work of transferring data from the processor, in effect allowing the processor to do other things while the transfer is taking place.

There are two distinct types of direct memory access: singleword (8-bit) and multiword (16-bit) DMA. Singleword DMA modes were removed from the ATA-3 and later specifications and are obsolete. DMA modes are also sometimes called *busmaster* ATA modes because they use a host adapter that supports busmastering. Ordinary DMA relies on the legacy DMA controller on the motherboard to perform the complex task of arbitration, grabbing the system bus and transferring the data. In the case of busmastering DMA, all this is done by a higher-speed logic chip in the host adapter interface (which is also on the motherboard).

Systems using the Intel PIIX (PCI IDE ISA eXcelerator) and later South Bridge chips have the capability of supporting busmaster IDE. The singleword and doubleword busmaster IDE modes and transfer rates are shown in Tables 7.13 and 7.14.

Table 7.13 Singleword (8-bit) DMA Modes and Transfer Rates

8-bit DMA Mode	Bus Width (bits)	Cycle Speed (ns)	Bus Speed (MHz)	Cycles per Clock	Transfer Rate (MB/sec)	ATA Specification
0	16	960	1.04	1	2.08	ATA-1[1]
1	16	480	2.08	1	4.17	ATA-1[1]
2	16	240	4.17	1	8.33	ATA-1[1]

1. Singleword (8-bit) DMA modes were removed from the ATA-3 and later specifications.

Table 7.14 Multiword (16-bit) DMA Modes and Transfer Rates

16-bit DMA Mode	Bus Width (bits)	Cycle Speed (ns)	Bus Speed (MHz)	Cycles per Clock	Transfer Rate (MB/sec)	ATA Specification
0	16	480	2.08	1	4.17	ATA-1
1	16	150	6.67	1	13.33	ATA-2
2	16	120	8.33	1	16.67	ATA-2

ATA-2 was also referred to as EIDE (Enhanced IDE) or Fast-ATA.

Note that doubleword DMA modes are also called busmaster DMA modes by some manufacturers. Unfortunately, even the fastest doubleword DMA Mode 2 results in the same 16.67MB/sec transfer speed as PIO Mode 4, so DMA modes have never really caught on as being desirable. However, even though the transfer speed is the same as PIO because DMA offloads much of the work from the processor, overall system performance would be higher. Even so, multiword DMA modes were never very popular and have been superseded by the newer Ultra-DMA modes supported in ATA-4–compatible devices.

Table 7.15 shows the Ultra-DMA modes now supported in the ATA-4 and ATA-5 specifications.

Table 7.15 Ultra-DMA Support in ATA-4 and ATA-5

Ultra DMA Mode	Bus Width (bits)	Cycle Speed (ns)	Bus Speed (MHz)	Cycles per Clock	Transfer Rate (MB/sec)	ATA Specification
0	16	240	4.17	2	16.67	ATA-4
1	16	160	6.25	2	25.00	ATA-4
2	16	120	8.33	2	33.33	ATA-4
3	16	90	11.11	2	44.44	ATA-5
4	16	60	16.67	2	66.67	ATA-5
5	16	40	25.00	2	100.00	ATA-6

ATA-4 UDMA Mode 2 is sometimes called Ultra-ATA/33 or ATA-33.

ATA-5 UDMA Mode 4 is sometimes called Ultra-ATA/66 or ATA-66.

ATA-6 UDMA Mode 5 is sometimes called Ultra-ATA/100 or ATA-100.

ATAPI (ATA Packet Interface)

ATAPI is a standard designed to provide the commands needed for devices such as CD-ROMs and tape drives that plug into an ordinary ATA (IDE) connector. The principal advantage of ATAPI hardware is that it's cheap and works on your current adapter. For CD-ROMs, it has a somewhat lower CPU usage compared to proprietary adapters, but there's no performance gain otherwise. For tape drives, ATAPI has potential for superior performance and reliability compared to the popular floppy controller attached tape devices. ATAPI is also used to run other removable storage devices, such as the LS-120 superdisk drives and internal Iomega Zip and Jaz drives.

Although ATAPI CD-ROMs use the hard disk interface, this does not mean they look like ordinary hard disks; to the contrary, from a software point of view, they are a completely different kind of animal. They actually most closely resemble a SCSI device. All modern IDE CD-ROMs support the ATAPI protocols, and generally the terms are synonymous. In other words, an ATAPI CD-ROM is an IDE CD-ROM and vice versa.

Caution

ATAPI support is not found directly in the BIOS of many systems. Systems without ATAPI support in the BIOS cannot boot from an ATAPI CD-ROM, and you still must load a driver to use ATAPI under DOS or Windows. Windows 95 and later (including 98 and Me) and Windows NT (including Windows 2000 and XP) have native ATAPI support, and newer systems with ATAPI-aware BIOSes are now available, which allow booting from an ATAPI CD-ROM. Some versions of the Windows 98, NT, 2000, and XP CD-ROMs are directly bootable on those systems, greatly easing installation.

I normally recommend keeping different types of IDE devices on separate channels. Some older chipsets cannot support setting different transfer rates for different devices, which means the channel must be set to the speed of the slowest device. Because most CD-ROM and tape drives run at lower IDE mode speeds, this forces your hard disk to run more slowly if they share a single cable. Even if the chipset you have supports separate speed settings for devices on the same channel (cable), I still recommend keeping them separate because IDE does not normally support overlapping access, such as SCSI. So, when one drive is running, the other cannot be accessed. By keeping the CD-ROM and hard disk on separate channels, you can more effectively overlap accessing between them.

Serial ATA

With the introduction of ATA-6, it seems that the parallel ATA standard that has been in use for more than 10 years is running out of steam. Sending data at rates faster than 100MB/sec down a parallel ribbon cable is fraught with all kinds of problems because of signal timing, electromagnetic interference (EMI), and other integrity problems. The solution is in a new ATA interface called serial ATA, which is an evolutionary backward-compatible replacement for the parallel ATA physical storage interface. Serial ATA is backward compatible in that it is compatible with existing software, which will run on the new architecture without any changes. In other words, the existing BIOS, operating systems, and utilities that work on parallel ATA will also work on serial ATA. This means Serial ATA supports all existing ATA and ATAPI devices, including CD-ROM and CD-RW drives, DVD drives, tape devices, SuperDisk drives, and any other storage device currently supported by parallel ATA.

Of course, they do differ physically—that is, you won't be able to plug parallel ATA drives into serial ATA host adapters and vice versa. The physical changes are all for the better because serial ATA uses much thinner cables with only 7 pins that are easier to route inside the PC and easier to plug in with smaller redesigned cable connectors. The interface chip designs also are improved with fewer pins and lower voltages. These improvements are all designed to eliminate the design problems inherent in parallel ATA.

Serial ATA (SATA) won't be integrated into PCs overnight; however, it is clear to me that it will eventually replace parallel ATA as the de facto standard internal storage device interface found in PCs. The transition from ATA to SATA is a gradual one, and during this transition parallel ATA capabilities will continue to be available. I would also expect that with more than a 10-year history, parallel ATA devices will continue to be available even after most PCs have gone to SATA.

Development for Serial ATA started when the Serial ATA Working Group effort was announced at the Intel Developer Forum in February 2000. The initial members of the Serial ATA Working Group included APT Technologies, Dell, IBM, Intel, Maxtor, Quantum, and Seagate. The first serial ATA specification 1.0 was completed in November 2000, and can be downloaded from the Serial ATA Working Group Web site at `http://www.serialata.org`. Since forming, the group has added more than 60 Contributor and Adopter companies to the membership from all areas of industry. It is expected that by the beginning of 2002, serial ATA will be shipping in many new systems.

The performance of SATA is impressive. Currently, three versions of the standard are available, which all use the same cables and connectors; they differ only in transfer rate performance. Initially, only the first version will be available, but the roadmap to doubling and quadrupling performance from there has been clearly established. Table 7.15 shows the specifications for each of the three SATA versions.

Table 7.16 SATA Standards Specifications

Serial ATA Type	Bus Width (bits)	Bus Speed (MHz)	Data Cycles per Clock	Bandwidth (MB/sec)
SATA-150	1	1500	1	150
SATA-300	1	3000	1	300
SATA-600	1	6000	1	600

From the table, you can see that serial ATA sends data only a single bit at a time. The cable used has only 7 wires and is a very thin design, with keyed connectors only 14mm (0.55 inches) wide on each end. This eliminates problems with airflow around the wider parallel ATA ribbon cables. Each cable has connectors only at each end and connects the device directly to the host adapter (normally on the motherboard). There are no master/slave settings because each cable supports only a single device. The cable ends are interchangeable—the connector on the motherboard is the same as on the device, and both cable ends are identical. Maximum SATA cable length is 1 meter (39.37 inches), which is considerably longer than the 18-inch maximum for parallel ATA. Even with this thinner, longer, and less expensive cable, transfer rates initially of 150MB/sec (one and a half times greater than parallel ATA/100) and in the future up to 300MB/sec and even 600MB/sec are possible.

Serial ATA uses a special encoding scheme called 8B/10B to encode and decode data sent along the cable. The 8B/10B transmission code originally was developed (and patented) by IBM in the early 1980s for use in high-speed data communications. This encoding scheme is now used by many high-speed data transmission standards, including Gigabit Ethernet, Fibre Channel, FireWire, and others. The main purpose of the 8B/10B encoding scheme is to guarantee that there are never more than four 0s (or 1s) transmitted consecutively. This is a form of Run Length Limited (RLL) encoding called RLL 0,4 in which the 0 represents the minimum and the 4 represents the maximum number of consecutive 0s in each encoded character.

8B/10B encoding also ensures that there are never more than six or less than four 0s (or 1s) in a single encoded 10-bit character. Because 1s and 0s are sent as voltage changes on a wire, this ensures that the spacing between the voltage transitions sent by the transmitter will be fairly balanced, with a more regular and steady stream of pulses. This presents a more steady load on the circuits, increasing reliability. The conversion from 8-bit data to 10-bit encoded characters for transmission leaves a number of 10-bit patterns unused. Several of these additional patterns are used to provide flow control, delimit packets of data, perform error checking, or perform other special needs.

The physical transmission scheme for SATA uses what is called differential NRZ (Non-Return to Zero). This uses a balanced pair of wires, each carrying plus or minus 0.25V (one quarter-volt). The signals are sent differentially: If one wire in the pair is carrying +0.25V, the other wire is carrying -0.25V, where the differential voltage between the two wires is always 0.5V (a half-volt). This means that for a given voltage waveform, the opposite voltage waveform is sent along the adjacent wire. Differential transmission minimizes electromagnetic radiation and makes the signals easier to read on the receiving end.

A 15-pin power cable and power connector is optional with SATA, providing 3.3V power in addition to the 5V and 12V provided via the industry-standard 4-pin device power connectors. Although it has 15 pins, this new power connector design is only 24mm (0.945 inches). With 3 pins designated for each of the 3.3V, 5V, and 12V power levels, enough capacity exists for up to 4.5 amps of current at each voltage, which is ample for even the most power-hungry drives. For compatibility with existing power supplies, SATA drives can be made with either the original, standard 4-pin device power connector or the new 15-pin SATA power connector, or both.

Figure 7.6 shows what the new SATA signal and power connectors look like.

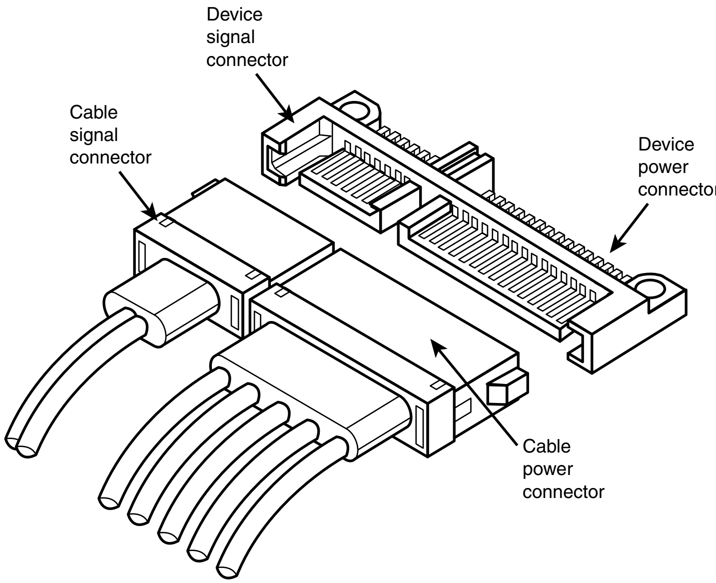

Figure 7.6 SATA (Serial ATA) signal and power connectors.

The pinouts for the Serial ATA data and optional power connectors are shown in Tables 7.17 and 7.18.

Table 7.17 Serial ATA (SATA) Data Connector Pinout

Signal Pin	Signal	Description
S1	Gnd	First mate
S2	A+	Host Transmit +
S3	A-	Host Transmit -
S4	Gnd	First mate
S5	B-	Host Receive -
S6	B+	Host Receive +
S7	Gnd	First mate

All pins are in a single row spaced 1.27mm (.050") apart.
All ground pins are longer so they will make contact before the signal/power pins to allow hot plugging.

Table 7.18 Serial ATA (SATA) Optional Power Connector Pinout

Power Pin	Signal	Description
P1	+3.3V	3.3V power
P2	+3.3V	3.3V power
P3	+3.3V	3.3V power

Table 7.18 Continued

Power Pin	Signal	Description
P4	Gnd	First mate
P5	Gnd	First mate
P6	Gnd	First mate
P7	+5V	5V power
P8	+5V	5V power
P9	+5V	5V power
P10	Gnd	First mate
P11	Gnd	First mate
P12	Gnd	First mate
P13	+12V	12V power
P14	+12V	12V power
P15	+12V	12V power

All pins are in a single row spaced 1.27mm (.050") apart.

All ground pins are longer so they will make contact before the signal/power pins to allow hot plugging.

Three power pins are used to carry 4.5 A maximum current for each voltage.

Configuration of serial ATA devices is also much simpler because the master/slave or cable select jumper settings used with parallel ATA are no longer necessary.

As with parallel ATA, serial ATA was designed to be the primary storage interface used inside a PC and was not designed to be used as an external interface. As such, SATA is not designed to compete with high-speed external device interfaces, such as SCSI, USB 2.0, or IEEE-1394 (FireWire). Therefore, I expect it to replace parallel ATA in systems over the next few years.

ATA RAID

RAID is an acronym for Redundant Array of Independent (or Inexpensive) Disks and was designed to improve the fault tolerance and performance of computer storage systems. RAID was first developed at the University of California at Berkeley in 1987, and was designed so that a group of smaller, less expensive drives could be interconnected with special hardware and software to make them appear as a single larger drive to the system. By using multiple drives to act as one drive, increases in fault tolerance and performance could be realized.

Initially, RAID was conceived to simply have all the individual drives in the array work together as a single larger drive with the combined storage space of all the individual drives added up. However, this actually reduced reliability and didn't do much for performance, either. For example, if you had four drives connected in an array acting as one drive, you would be four times as likely to experience a drive failure than if you used just a single larger drive. To improve on the reliability and performance, the Berkeley scientists proposed six levels (corresponding to different methods) of RAID. These levels provide varying emphasis on either fault tolerance (reliability), storage capacity, performance, or a combination of the three.

An organization called the RAID Advisory Board (RAB) was formed in July of 1992 to standardize, classify, and educate on the subject of RAID. They can be reached on the Web at `http://www.raid-advisory.com`. The RAB has developed specifications for RAID, a conformance program for the various RAID levels, and a classification program for RAID hardware.

Currently, seven standard RAID levels are defined by the RAID Advisory Board, called RAID 0 through 6. RAID normally is implemented by a RAID controller board, although software-only implementations are possible (but not recommended). The levels are as follows:

- *RAID Level 0—Striping.* File data is written simultaneously to multiple drives in the array, which act as a single larger drive. Offers high read/write performance but very low reliability. Requires a minimum of two drives to implement.
- *RAID Level 1—Mirroring.* Data written to one drive is duplicated on another, providing excellent fault tolerance (if one drive fails, the other will be used and no data lost), but no real increase in performance as compared to a single drive. Requires a minimum of two drives to implement (same capacity as one drive).
- *RAID Level 2—Bit-level ECC.* Data is split one bit at a time across multiple drives, and Error Correction Codes are written to other drives. Intended for storage devices that do not incorporate ECC internally (all SCSI and ATA drives have internal ECC). Provides high data rates with good fault tolerance, but large numbers of drives are required, and no commercial RAID 2 controllers or drives without ECC are available on the market that I am aware of.
- *RAID Level 3—Striped with parity.* Combines RAID Level 0 striping with an additional drive used for parity information. This RAID level is really an adaptation of RAID Level 0 that sacrifices some capacity, for the same number of drives. However, it also achieves a high level of data integrity or fault tolerance because data usually can be rebuilt if one drive fails. Requires a minimum of three drives to implement (two or more for data and one for parity).
- *RAID Level 4—Blocked data with parity.* Similar to RAID 3 except data is written in larger blocks to the independent drives, offering faster read performance with larger files. Requires a minimum of three drives to implement (two or more for data and one for parity).
- *RAID Level 5—Blocked data with distributed parity.* Similar to RAID 4 but offers improved performance by distributing the parity stripes over a series of hard drives. Requires a minimum of three drives to implement (two or more for data and one for parity).
- *RAID Level 6—Blocked data with double distributed parity.* Similar to RAID 5 except parity information is written twice using two different parity schemes to provide even better fault tolerance in case of multiple drive failures. Requires a minimum of four drives to implement (two or more for data and two for parity).

Additional RAID levels exist that are not supported by the RAID Advisory Board but which are instead custom implementations by specific companies. Note that the higher the number doesn't necessarily mean increased performance or fault tolerance; the numbered order of the RAID levels was entirely arbitrary.

Until recently, virtually all RAID controllers were SCSI based, meaning they used SCSI drives. For a professional setup, SCSI RAID is definitely the way to go because it combines the advantages of RAID with the advantages of SCSI—an interface that already was designed to support multiple drives. Now, however, ATA RAID controllers are available, allowing for even less expensive RAID implementations. These ATA RAID controllers usually are used in single-user systems for performance rather than reliability increases.

Most ATA RAID implementations are much simpler than the professional SCSI RAID adapters used on network file servers. ATA RAID is designed more for the individual who is seeking performance or simple drive mirroring for redundancy. When set up for performance, ATA RAID adapters run RAID Level 0, which incorporates data striping. Unfortunately, RAID 0 also sacrifices reliability such that if one drive fails, all data is lost. With RAID 0, performance scales up with the number of drives you add in the array. If you use four drives, you won't necessarily have four times the performance of a single drive, but it can be close to that for sustained transfers. Some overhead is still involved in the controller performing the striping and issues still exist with latency—that is, how long it takes to find the data—but performance will be higher than any single drive can normally achieve.

When set up for reliability, ATA RAID adapters generally run RAID Level 1, which is simple drive mirroring. All data written to one drive is written to the other. If one drive fails, the system can continue to work on the other drive. Unfortunately, this does not increase performance at all, and it also means you get to use only half of the available drive capacity. In other words, you must install two drives, but you get to use only one (the other is the mirror).

Combining performance with fault tolerance requires using one of the other RAID levels, such as 3 or 5. For example, virtually all professional RAID controllers used in network file servers are designed to use RAID Level 5. Controllers that implement RAID Level 5 are more expensive, and at least three drives must be connected. To improve reliability, but at a lower cost, many of the ATA RAID controllers enable combinations of the RAID levels—such as 0 and 1 combined. This usually requires four drives, two of which are striped together in a RAID Level 0 arrangement, which is then redundantly written to a second set of two drives in a RAID Level 1 arrangement. This enables you to have approximately double the performance of a single drive, and you have a backup set should one of the primary set fail.

Today, you can get IDE RAID controllers from companies such as Arco Computer Products, Iwill, Promise Technology, and more. A typical example of an ATA RAID controller is the Promise FastTrak 100/TX4. This controller enables up to four drives to be attached, and you can run them in RAID Level 0, 1, or 0+1 mode. This card also uses separate ATA data channels (cables) for each drive, allowing maximum performance. Promise Technology also has a less expensive ATA RAID card called the FastTrak 100/TX2, which has only two channels. You can still attach up to four drives, but because they share two ATA cables, performance isn't as good as if they were on separate cables. This is because only one drive can transfer on the cable at a time, which cuts performance in half.

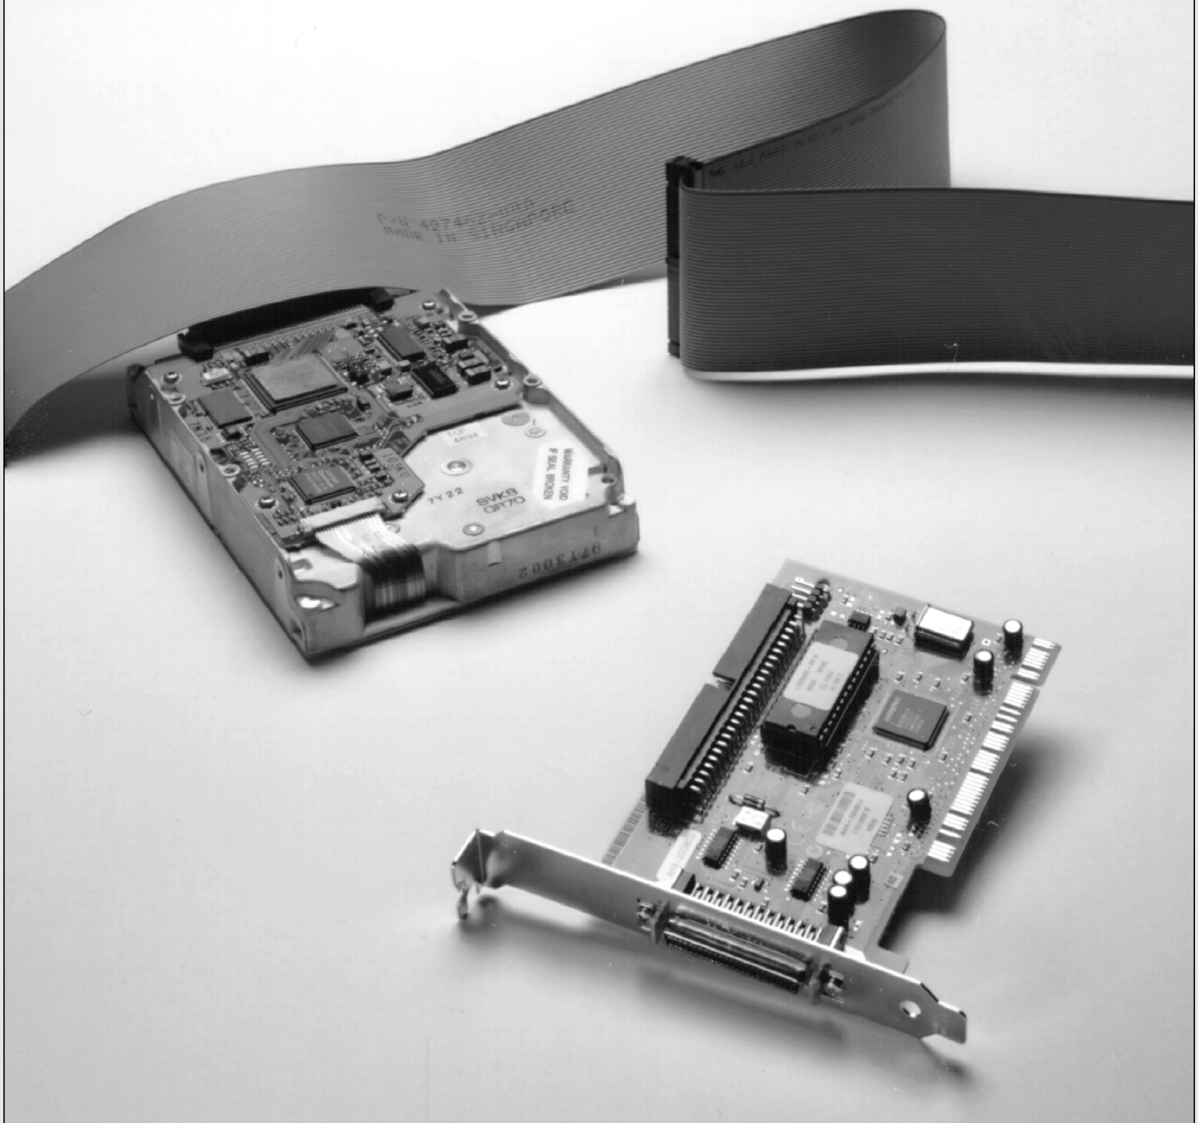
If you are looking for an ATA RAID controller, things to look for include

- RAID levels supported (most support 0, 1, and 0+1 combined)
- Two or four channels
- Support for ATA/100 speeds
- Support for 33MHz or 66MHz PCI slots

If you want to experiment with RAID inexpensively, you can implement RAID without a custom controller when using certain higher-end (often server-based) operating systems. For example, Windows NT/2000 and XP Server operating systems provide a software implementation for RAID using both striping and mirroring. In these operating systems, the Disk Administrator tool is used to set up and control the RAID functions, as well as to reconstruct the volume when a failure has occurred. Normally, though, if you are building a server in which the ultimate in performance and reliability are desired, you should look for ATA or SCSI RAID controllers that support RAID Level 3 or 5.

CHAPTER 8

The SCSI Interface



Small Computer System Interface

SCSI (pronounced "scuzzy") stands for Small Computer System Interface and is a general-purpose interface used for connecting many types of devices to a PC. This interface has its roots in SASI, the Shugart Associates System Interface. SCSI is the most popular interface for attaching high-speed disk drives to higher-performance PCs, such as workstations or network servers. SCSI is also very flexible; it is not only a disk interface, but is also a systems-level interface allowing many types of devices to be connected. SCSI is a bus that supports as many as 7 or 15 total devices. Multichannel adapters exist that can support up to 7 or 15 devices per channel.

The SCSI controller, called the *host adapter*, functions as the gateway between the SCSI bus and the PC system bus. Each device on the bus has a controller built in. The SCSI bus does not talk directly with devices such as hard disks; instead, it talks to the controller that is built into the drive.

A single SCSI bus can support as many as 8 or 16 physical units, usually called SCSI *IDs*. One of these units is the SCSI host adapter card in your PC; the other 7 or 15 can be other peripherals. You could have hard disks, tape drives, CD-ROM drives, a graphics scanner, or other devices attached to a single SCSI host adapter. Most systems can support up to four host adapters, each with up to 15 devices, for a total of 60 devices! There are even dual channel adapters that could double that figure.

SCSI is a fast interface, generally suited to high-performance workstations, servers, or anywhere the ultimate in performance for a storage system interface is needed. The latest Ultra4 (Ultra320) SCSI version supports transfer speeds of up to 320MB/sec!

When you purchase a SCSI device such as a SCSI hard disk, you usually are purchasing the device, controller, and SCSI adapter in one circuit; as such the device is ready to connect directly to the SCSI bus. This type of drive usually is called an *embedded* SCSI device—the SCSI interface is built in. For example, most SCSI hard drives are technically the same as their IDE counterparts except for the addition of the SCSI bus adapter circuits (normally a single chip) added to the controller board. You do not need to know what type of controller is inside the SCSI drive because your system cannot talk directly to the controller as though it were plugged into the system bus, like on a standard IDE drive. Instead, communications go through the SCSI host adapter installed in the system bus. You can access the drive only with the SCSI protocols.

Apple originally rallied around SCSI as being an inexpensive way out of the bind in which it put itself with the Macintosh. When the engineers at Apple realized their mistake in making the Macintosh a closed system (with no expansion slots), they decided that the easiest way to gain expandability was to build a SCSI port into the system, which is how external peripherals were originally added to the slotless Macs. Of course, in keeping with Apple tradition, they used a nonstandard SCSI connector. Now that Apple is designing systems with expansion slots, Universal Serial Bus (USB), and FireWire (iLINK or IEEE-1394), SCSI has been dropped from most Macs as a built-in option. Because PC systems always have been expandable, the push toward SCSI has not been as urgent. With up to eight or more bus slots supporting various devices and controllers in PC-compatible systems, it seemed as though SCSI was not as necessary for system expansion. In fact, with modern PCs sporting inexpensive built-in USB ports for external expansion, in most cases SCSI devices are necessary only when top performance is a critical issue.

SCSI has become popular in the PC-based workstation market because of the performance and expandability it offers. One block that stalled acceptance of SCSI in the early PC marketplace was the lack of a real standard; the SCSI standard originally was designed by one company and then turned into a committee-controlled public standard. Since then, no single manufacturer has controlled it.

Note

Most SCSI host adapters bundled with hardware, such as graphics scanners or SCSI CD-ROM, CD-R, or CD-RW drives, will not include all the features needed to support multiple SCSI devices or bootable SCSI hard drives. This has nothing to do with any limitations in the SCSI specification. The situation is simply that the manufacturer has included the most stripped-down version of a SCSI adapter available to save money. It has all the functionality necessary to support the device it came with, but nothing else. Fortunately, with the right adapter and drivers, one SCSI card could support all the SCSI devices in a system from hard drives to optical drives, scanners, tape drives, and more.

In the beginning, SCSI adapters lacked the capability to boot from hard disks on the SCSI bus. Booting from these drives and using a variety of operating systems was a problem that resulted from the lack of a software interface standard. The standard BIOS software in PC systems is designed to talk to ST-506/412, ESDI, or ATA (IDE) hard disks and devices. SCSI is so different from ATA/IDE that a new set of ROM BIOS routines is necessary to support the system so it can self-boot. Also, this BIOS support is unique to the SCSI host adapter you are using; so, unless the host adapter is built into your motherboard, this support won't be found in your motherboard BIOS. Instead, SCSI host adapters are available with BIOS support for SCSI hard disk drives right on the SCSI host adapter itself.

Note

For more information about the ST-506/412 Interface and the ESDI Interface, see "ST-506/412 Interface" and "ESDI Interface," respectively, in the Technical Reference section of the CD accompanying this book. An expanded discussion of both technologies can be found in *Upgrading and Repairing PCs, 6th Edition*, which is included in its entirety in PDF format on the CD with this book.

Because of the lead taken by Apple in developing systems software (operating systems and ROM) support for SCSI, peripherals connect to Apple systems in fairly standard ways. Until recently, this kind of standard-setting leadership was lacking for SCSI in the PC world. This situation changed dramatically with Windows 95 and later versions, which include drivers for most popular SCSI adapters and peripherals on the market. These days, Windows 98/Me and Windows 2000 include even more drivers and support for SCSI adapters and devices built in.

Many PC manufacturers have standardized SCSI for high-end systems. In these systems, a SCSI host adapter card is placed in one of the slots, or the system has a SCSI host adapter built into the motherboard. This arrangement is similar in appearance to the IDE interface because a single cable runs from the motherboard to the SCSI drive. SCSI supports as many as 7 or 15 additional devices per bus (some of which might not be hard disks), whereas IDE supports only 4 devices (2 per controller). Additionally, SCSI supports more types of devices other than hard disks than IDE supports. IDE devices must be a hard disk, an IDE-type CD-ROM drive, a tape drive, an LS-120 SuperDisk drive, a Zip drive, and so on. Systems with SCSI drives are easy to upgrade because virtually any third-party SCSI drive will plug in and function.

ANSI SCSI Standards

The SCSI standard defines the physical and electrical parameters of a parallel I/O bus used to connect computers and peripheral devices in daisy-chain fashion. The standard supports devices such as disk drives, tape drives, and CD-ROM drives. The original SCSI standard (ANSI X3.131-1986) was approved in 1986, SCSI-2 was approved in January 1994, and the first portions of SCSI-3 were approved in 1995. Note that SCSI-3 has evolved into an enormous standard with numerous sections and is an evolving, growing standard still very much under development. Because it has been broken down into multiple standards, there really is no single SCSI-3 standard.

The SCSI interface is defined as a standard by ANSI (American National Standards Institute), specifically by a committee currently known as T10. T10 is a technical committee of the National Committee on Information Technology Standards (NCITS, pronounced "insights"). NCITS is accredited by ANSI and operates under rules approved by ANSI. These rules are designed to ensure that voluntary standards are developed by the consensus of industry groups. NCITS develops information-processing system standards, whereas ANSI approves the process under which they are developed and publishes them. Working draft copies of all SCSI-related standards can be downloaded from the T10 Technical Committee site at `http://www.t10.org`.

One problem with the original SCSI-1 document was that many of the commands and features were optional, and there was little or no guarantee that a particular peripheral would support the expected commands. This problem caused the industry as a whole to define a set of 18 basic SCSI commands called the Common Command Set (CCS) to become the minimum set of commands supported by all peripherals. CCS became the basis for what is now the SCSI-2 specification.

Along with formal support for CCS, SCSI-2 provided additional definitions for commands to access CD-ROM drives (and their sound capabilities), tape drives, removable drives, optical drives, and several other peripherals. In addition, an optional higher speed called Fast SCSI-2 and a 16-bit version called Wide SCSI-2 were defined. Another feature of SCSI-2 is *command queuing*, which enables a device to accept multiple commands and execute them in the order that the device deems to be most efficient. This feature is most beneficial when you are using a multitasking operating system that could be sending several requests on the SCSI bus at the same time.

The X3T9 group approved the SCSI-2 standard as X3.131-1990 in August 1990, but the document was recalled in December 1990 for changes before final ANSI publication. Final approval for the SCSI-2 document was finally made in January 1994, although it has changed little from the original 1990 release. The SCSI-2 document is now called ANSI X3.131-1994. The official document is available from Global Engineering Documents or the ANSI committee—both are listed in the Vendor List on the CD. You can also download working drafts of these documents from the T10 Technical Committee home page as listed previously.

Most companies indicate that their host adapters follow both the ANSI X3.131-1986 (SCSI-1) and the X3.131-1994 (SCSI-2) standards. Note that because virtually all parts of SCSI-1 are supported in SCSI-2, virtually any SCSI-1 device is also considered SCSI-2 by default. Many manufacturers advertise that their devices are SCSI-2, but this does not mean they support any of the additional optional features that were incorporated in the SCSI-2 revision.

For example, an optional part of the SCSI-2 specification includes a fast synchronous mode that doubles the standard synchronous transfer rate from 5MB/sec to 10MB/sec. This Fast SCSI transfer mode can be combined with 16-bit Wide SCSI for transfer rates of up to 20MB/sec. An optional 32-bit version was defined in SCSI-2, but component manufacturers have shunned this as too expensive. In essence, 32-bit SCSI was a stillborn specification, as it was withdrawn from the SCSI-3 standard. Most SCSI implementations are 8-bit standard SCSI or 16-bit Fast/Wide SCSI. Even devices that support none of the Fast or Wide modes can still be considered SCSI-2.

SCSI-3 is broken down into a number of standards. The SCSI Parallel Interface (SPI) standard controls the parallel interconnection between SCSI devices, which is mostly what we are talking about here. So far several versions of SPI have existed, including SPI, SPI-2, SPI-3, and SPI-4. Versions through SPI-3 have been published, whereas SPI-4 is still in draft form.

What can be confusing is that several terms can be used to describe the newer SPI standards, as shown in Table 8.1.

Table 8.1 SPI (SCSI Parallel Interface) Standards

SCSI-3 Standard	Also Known As	Speed	Throughput
SPI	Ultra SCSI	Fast-20	20/40MB/sec
SPI-2	Ultra2 SCSI	Fast-40	40/80MB/sec
SPI-3	Ultra3 SCSI	Fast-80DT	160MB/sec
SPI-4	Ultra4 SCSI	Fast-160DT	320MB/sec

To add to the confusion, SPI-3 or Ultra3 SCSI is also called Ultra160 or Ultra160+, and SPI-4 or Ultra4 SCSI is also called Ultra320 or Ultra320+ by some companies. The Ultra160/320 designation refers to any device that includes the first three of the five main features from the Ultra3/4 SCSI specification. Ultra160/320+ refers to any device that supports all five main features of Ultra3/4 SCSI.

Table 8.2 shows the maximum transfer rates for the SCSI bus at various speeds and widths and the cable type required for the specific transfer widths.

Note

The A cable is the standard 50-pin SCSI cable, whereas the P cable is a 68-pin cable designed for 16-bit transfers. High Voltage Differential (HVD) signaling was never popular and is now considered obsolete. LVD (Low Voltage Differential) signaling is used in the Ultra2 and Ultra3 modes to increase performance and cabling lengths. Pinouts for the cable connections are listed in this chapter in Tables 8.3–8.6.

SCSI is both forward and backward compatible, meaning one can run faster devices on buses with slower host adapters or vice versa. In each case, the entire bus will run at the lowest common denominator speed. In fact, as was stated earlier, virtually any SCSI-1 device can also legitimately be called SCSI-2 (or even SCSI-3) because most of the improvements in the later versions are optional. Of course, you can't take advantage of the faster modes on an older, slower host adapter. By the same token, you can purchase an Ultra3 capable SCSI host adapter and still run older standard SCSI devices. You can even mix standard 8-bit and wide 16-bit devices on the same bus using cable adapters.

SCSI-1

SCSI-1 was the first implementation of SCSI. It was officially known as ANSI X3.131-1986. The major features of SCSI-1 were

- 8-bit parallel bus
- 5MHz asynchronous or synchronous operation
- 4MB/sec (asynchronous) or 5MB/sec (synchronous) throughput
- 50-pin cables with low-density pin-header internal and Centronics-style external connectors
- Single-ended (SE) unbalanced transmission
- Passive termination
- Optional bus parity

SCSI-1 is now considered obsolete; in fact, the standard has been withdrawn by ANSI and replaced by SCSI-2.

Table 8.2 SCSI Types, Data-Transfer Rates, and Cables

SCSI Standard	SCSI Technology	Marketing Term	Clock Speed (MHz)	Transfer Width
SCSI-1	Async	Asynchronous	5	8-bit
SCSI-1	Fast-5	Synchronous	5	8-bit
SCSI-2	Fast-5/Wide	Wide	5	16-bit
SCSI-2	Fast-10	Fast	10	8-bit
SCSI-2	Fast-10/Wide	Fast/Wide	10	16-bit
SPI (SCSI-3)	Fast-20	Ultra	20	8-bit
SPI (SCSI-3)	Fast-20/Wide	Ultra/Wide	20	16-bit
SPI-2 (SCSI-3)	Fast-40	Ultra2	40	8-bit
SPI-2 (SCSI-3)	Fast-40/Wide	Ultra2/Wide	40	16-bit
SPI-3 (SCSI-3)	Fast-80DT	Ultra3 (Ultra160)	40[3]	16-bit
SPI-4 (SCSI-3)	Fast-160DT	Ultra4 (Ultra320)	80[3]	16-bit

**Not including the host adapter.*

Cable Lengths are in meters: 25M = 80ft., 12M = 40ft., 6M = 20ft., 3M = 10ft., 1.5M = 5ft.

SE = Single-ended signaling;

HVD = High Voltage Differential signaling, obsolete

LVD = Low Voltage Differential signaling

SPI = SCSI Parallel Interface, part of SCSI-3

SCSI-2

SCSI-2 is officially known as ANSI X3.131-1994. The SCSI-2 specification is essentially an improved version of SCSI-1 with some parts of the specification tightened and several new features and options added. Normally, SCSI-1 and SCSI-2 devices are compatible, but SCSI-1 devices ignore the additional features in SCSI-2.

Some of the changes in SCSI-2 are very minor. For example, SCSI-1 allowed SCSI bus parity to be optional, whereas parity must be implemented in SCSI-2. Parity is an extra bit that is sent as a verification bit to ensure that the data is not corrupted. Another requirement is that initiator devices, such as host adapters, provide terminator power to the interface; most devices already did so.

SCSI-2 also added several optional features:

- Fast SCSI (10MHz)
- Wide SCSI (16-bit transfers)
- Command queuing
- New commands
- High-density, 50-pin cable connectors
- Active (Alternative 2) termination for improved single-ended (SE) transmission
- High Voltage Differential (HVD) transmission (incompatible with SE on the same bus) for longer bus lengths

Transfer Speed (MB/s)	Max. No. of Devices*	Cable Type	Max. Length (SE)	Max. Length (HVD)	Max. Length (LVD)
4	7	A (50-pin)	6M	25M	-
5	7	A (50-pin)	6M	25M	-
10	15	P (68-pin)	6M	25M	-
10	7	A (50-pin)	3M	25M	-
20	15	P (68-pin)	3M	25M	-
20	7	A (50-pin)	3/1.5M[1]	25M	-
40	7	P (68-pin)	3/1.5M[1]	25M	-
40	7	A (50-pin)	-	-	12M[2]
80	15	P (68-pin)	-	-	12M[2]
160	15	P (68-pin)	-	-	12M[2]
320	15	P (68-pin)	-	-	12M[2]

DT = Double transition, or two transfers per clock cycle, 16-bit only

1 = Ultra SCSI cable total length is restricted to 1.5M if more than 3 devices exist on the bus (not including the host adapter). A maximum of 7 devices is allowed.

2 = A 25M cable may be used if only one device exists (point-to-point interconnect).

3 = Ultra3 (Ultra160) and Ultra4 (Ultra320) SCSI transfer twice per clock cycle and are 16-bit only.

Wide SCSI enables parallel data transfer at a bus width of 16 bits. The wider connection requires a new cable design. The standard 50-conductor, 8-bit cable is called the A cable. SCSI-2 originally defined a special 68-conductor B cable that was supposed to be used in conjunction with the A cable for 32-bit wide transfers. However, because of a lack of industry support and the added expenses involved, 32-bit SCSI was never actually implemented and was finally removed as a part of the SCSI-3 specifications. Therefore, two different types of SCSI cables are now available, called the A cable and the P cable. A cables are any SCSI cables with 50-pin connectors, whereas P cables are any SCSI cables with 68-pin connectors. You need a P cable if you are connecting a Wide SCSI device and want it to work in 16-bit mode. The P cable was not officially included in the standard until SCSI-3.

Fast SCSI refers to high-speed synchronous transfer capability. Fast SCSI achieves a 10MB/sec transfer rate on the standard 8-bit SCSI cabling. When combined with a 16-bit Wide SCSI interface, this configuration results in data-transfer rates of 20MB/sec (called Fast/Wide).

The high-density connectors enable smaller, more efficient connector and cable designs.

In SCSI-1, an initiator device, such as a host adapter, was limited to sending one command per device. In SCSI-2, the host adapter can send as many as 256 commands to a single device, which will store and process those commands internally before responding on the SCSI bus. The target device even can resequence the commands to allow for the most efficient execution or performance possible. This is especially useful in multitasking environments, such as OS/2 and Windows NT, which can take advantage of this feature.

SCSI-2 took the Common Command Set that was being used throughout the industry and made it an official part of the standard. The CCS was designed mainly for disk drives and did not include specific commands designed for other types of devices. In SCSI-2, many of the old commands are reworked, and several new commands have been added. New command sets have been added for CD-ROMs, optical drives, scanners, communications devices, and media changers (jukeboxes).

The single-ended SCSI bus depends on very tight termination tolerances to function reliably. Unfortunately, the original 132-ohm passive termination defined in the SCSI-1 document was not designed for use at the higher synchronous speeds now possible. These passive terminators can cause signal reflections to generate errors when transfer rates increase or when more devices are added to the bus. SCSI-2 defines an active (voltage-regulated) terminator that lowers termination impedance to 110 ohms and improves system integrity. Note that LVD SCSI requires special LVD terminators. If you use SE terminators on a bus with LVD devices, they either won't work or, if they are multimode devices, will default to SE operation.

These features are not required; they are optional under the SCSI-2 specification. If you connect a standard SCSI host adapter to a Fast SCSI drive, for example, the interface will work, but only at standard SCSI speeds.

SCSI-3

SCSI-3 is a term used to describe a set of standards currently being developed. Simply put, it is the next generation of documents a product conforms to. Unlike SCSI-1 and SCSI-2, SCSI-3 is not one document that covers all the layers and interfaces of SCSI, but is instead a collection of documents that covers the primary commands, specific command sets, and electrical interfaces and protocols. The command sets include hard disk interface commands, commands for tape drives, controller commands for RAID (Redundant Array of Inexpensive Drives), and other commands as well. There is also an overall SCSI Architectural Model (SAM) for the physical and electrical interfaces, as well as a SCSI Parallel Interface standard that controls the form of SCSI most commonly used. Each document within the standard is now a separate publication with its own revision level—for example, within SCSI-3 three different versions of the SCSI Parallel Interface have been published. Normally we don't refer to SCSI-3 anymore as a specific interface and instead refer to the specific subsets of SCSI-3, such as SPI-3 (Ultra3 SCSI).

The main additions to SCSI-3 include

- Ultra2 (Fast-40) SCSI
- Ultra3 (Fast-80DT) SCSI
- Ultra4 (Fast-160DT) SCSI
- New Low Voltage Differential signaling
- Elimination of High Voltage Differential signaling

Breaking up SCSI-3 into many smaller individual standards has enabled the standard as a whole to develop more quickly. The individual substandards can now be published rather than waiting for the entire standard to be approved.

Figure 8.1 shows the main parts of SCSI-3.

The primary changes being seen in the marketplace from SCSI-3 are the new Fast-40 (Ultra2) and Fast-80DT (Ultra3) high-speed drives and adapters. These have taken the performance of SCSI up to 160MB/sec. Also new is the LVD electrical standard, which allows for greater cable lengths. The older High Voltage Differential signaling has been removed from the standard.

A number of people are confused over the speed variations in SCSI. Part of the problem is that speeds are quoted as either clock speeds (MHz) or transfer speeds. With 8-bit transfers, you get one byte per transfer, so if the clock is 40MHz (Fast-40 or Ultra2 SCSI), the transfer speed is 40MB/sec. On the other hand, if you are using a Wide (16-bit) interface, the transfer speed doubles to 80MB/sec, even though the clock speed remains at 40MHz. With Fast-80DT, the bus speed technically remains at 40MHz; however, two transfers are made per cycle, resulting in a throughput speed of 160MB/sec. The same is true for Ultra4 SCSI, which runs at 80MHz and transfers 2 bytes at a time and two transfers per cycle. Ultra4 is also called Ultra320 and is the fastest form of parallel SCSI today.

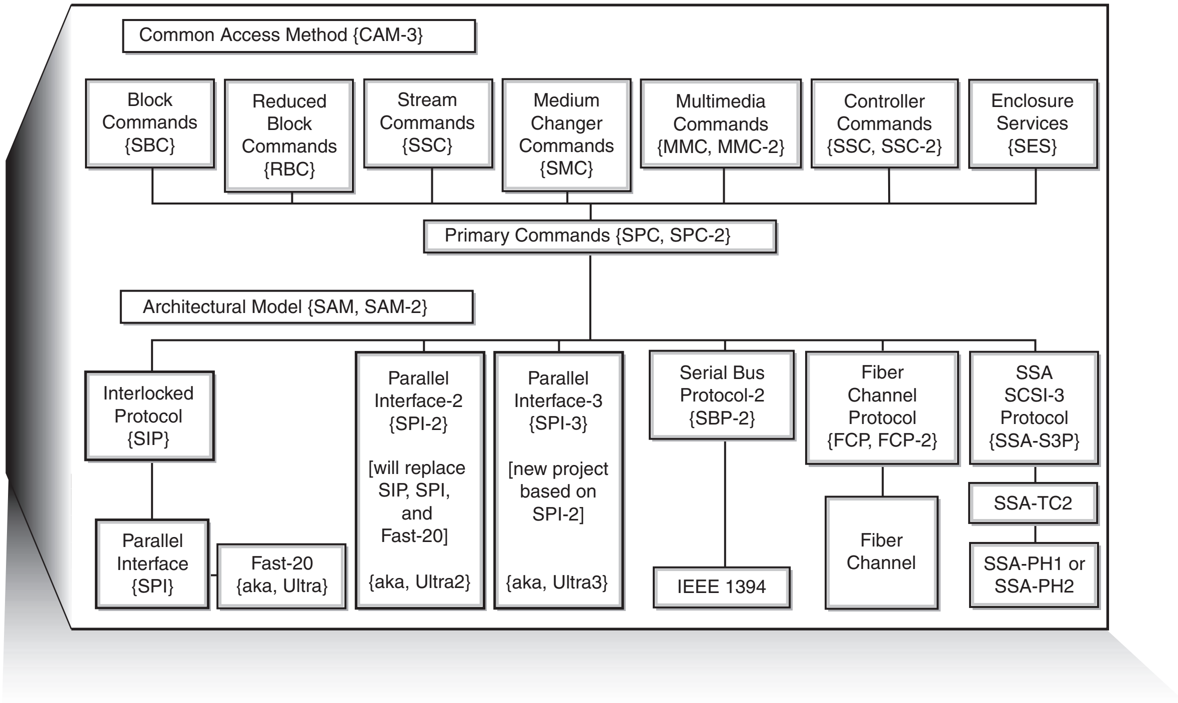


Figure 8.1 The SCSI-3 architecture.

Finally, confusion exists because SCSI speeds or modes are often discussed using either the official terms, such as Fast-10, Fast-20, Fast-40, and Fast-80DT, or the equivalent marketing terms, such as Fast, Ultra, Ultra2, and Ultra3 (also called Ultra160). Refer to Table 8.2 for a complete breakdown of SCSI official terms, marketing terms, and speeds.

The further evolution of the most commonly used form of SCSI is defined under the SPI standards within SCSI-3. The SPI standards are detailed in the following sections.

SPI or Ultra SCSI

The SCSI Parallel Interface standard was the first SCSI standard that fell under the SCSI-3 designation and is officially known as ANSI X3.253-1995. SPI is also called Ultra SCSI by most marketing departments and defines the parallel bus electrical connections and signals. A separate document called the SCSI Interlock Protocol (SIP) defines the parallel command set. SIP was included in the later SPI-2 and SPI-3 revisions and is no longer carried as a separate document. The main features added in SPI or Ultra SCSI are

- Fast-20 (Ultra) speeds (20MB/sec or 40MB/sec)
- 68-pin P-cable and connectors defined for Wide SCSI

SPI initially included speeds up to Fast SCSI (10MHz), which enables transfer speeds up to 20MB/sec using a 16-bit wide bus. Later, Fast-20 (20MHz), commonly known as Ultra SCSI, was added through an addendum document (ANSI X3.277-1996), allowing a throughput of 40MB/sec on a 16-bit wide bus (commonly called Ultra/Wide).

SPI-2 or Ultra2 SCSI

SPI-2 is also called Ultra2 SCSI, officially published as ANSI X3.302-1998, and adds several features to the prior versions:

- Fast-40 (Ultra2) speeds (40MB/sec or 80MB/sec)
- Low Voltage Differential signaling
- Single Connector Attachment (SCA-2) connectors
- 68-pin Very High Density Connector (VHDC)

The most notable of these is a higher speed called Fast-40, which is commonly called Ultra2 SCSI and runs at 40MHz. On a narrow (8-bit) bus, this results in 40MB/sec throughput, whereas on a wide bus (16-bit), this results in 80MB/sec throughput and is commonly referred to as Ultra2/Wide.

To achieve these speeds, a new electrical interface called LVD must be used. The slower single-ended electrical interface is only good for speeds up to Fast-20. Fast-40 mode requires LVD operation. The LVD signaling also enables longer cable lengths up to 12 meters with multiple devices or 25 meters with only one device. LVD and SE devices can share the same cable, but in that case the bus will run in SE mode and be restricted in length to as little as 1.5 meters in Fast-20 mode. LVD operation requires special LVD-only or LVD/SE multimode terminators. If multimode terminators are used, the same terminators will work on either SE or LVD buses.

The SPI-2 standard also includes SIP (SCSI Interlink Protocol) and defines the Single Connector Attachment (SCA-2) 80-pin connector for hot-swappable drive arrays. There is also a new 68-pin Very High Density Connector (VHDC), which is smaller than the previous types.

SCSI Signaling

"Normal," or standard, SCSI uses a signaling technique called single-ended signaling. SE signaling is a low-cost technique, but it also has performance and noise problems.

Single-ended signaling is also called unbalanced signaling. Each signal is carried on a pair of wires, normally twisted to help reduce noise. With SE one of the pair is grounded, often to a common ground for all signals, and the other carries the actual voltage transitions. It is up to a receiver at the other end of the cable to detect the voltage transitions, which are really just changes in voltage.

Unfortunately, this type of unbalanced signaling is very prone to problems with noise, electromagnetic interference, and ground leakage; these problems get worse the longer the cable is. This is the reason Ultra SCSI was limited to such short maximum bus lengths—as little as 1 1/2 meters or 5 feet.

When SCSI was first developed, a signaling technique called High Voltage Differential signaling was also introduced into the standard. Differential signaling, also known as *balanced signaling*, is still done with a pair of wires. In fact, the first in the pair carries the same type of signal that single-ended SCSI carries. The second in the pair, however, carries the logical inversion of that signal. The receiving device detects the difference between the pair (hence the name differential). By using the wires in a balanced pair, the receiver no longer needs to detect voltage magnitude, only the differential between voltage in two wires. This is much easier for circuits to do reliably, which makes them less susceptible to noise and enables greater cable length. Because of this, differential SCSI can be used with cable lengths of up to 25 meters, whereas single-ended SCSI is good only for 6 meters maximum, or as little as 1 1/2 meters in the faster modes.

Figure 8.2 shows the circuit differences between balanced (differential) and unbalanced (single-ended) transmission lines.

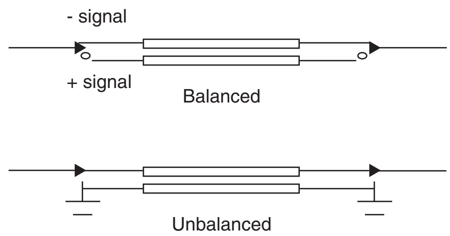

Figure 8.2 Balanced (differential) versus unbalanced (single-ended) signaling.

Unfortunately, the original standard for HVD signaling called for high voltage differentials between the two wires. This means that small, low-power, single-chip interfaces using HVD signaling could not be developed. Instead, circuits using several chips were required. This works at both ends, meaning both the host adapter and device circuitry had to be larger and more expensive.

Another problem with HVD SCSI is that although the cables and connectors look (and are) exactly the same as for SE SCSI, both types of devices cannot be mixed on the same bus. If they are, the high voltage from the HVD device will burn out the receiver circuits on all SE devices attached to the bus. In other words, the result will be smoked hardware—not a pretty sight.

Because SE SCSI worked well enough for the speeds that were necessary up until recently, HVD SCSI signaling never really caught on. It was used only in minicomputers and very rarely, if at all, in PCs. Because of this, the extra cost of this interface, and the fact that it is electrically incompatible with standard SE SCSI devices, HVD signaling was removed from the SCSI specification in the latest SCSI-3 documents. So, as far as we are concerned, it is obsolete.

Still, a need existed for a more reliable signaling technique that would allow for longer cable lengths. The answer came in the form of LVD signaling. By designing a new version of the differential interface, it can be made to work with inexpensive and low-power SCSI chips. Another advantage of LVD is that because it uses low voltage, if you plug an LVD device into an SE SCSI bus, nothing will be damaged. In fact, as an optional part of the LVD standard, the LVD device can be designed as a multimode device, which means it works on both SE and LVD buses. In the case of installing a multimode LVD device into an SE bus, the device detects that it is installed in an SE bus and defaults to SE mode.

This means that all multimode LVD/SE SCSI devices can be used on either LVD or SE SCSI buses. However, when on a bus with even one other SE device, all the LVD devices on the bus run only in SE mode. Because SE mode supports only SCSI speeds of up to 20MHz (Fast-20 or UltraSCSI) and cable lengths of up to 1 1/2 or 3 meters, the devices also work only at that speed or lower; you also might have problems with longer cables. Although you can purchase an Ultra3 SCSI multimode LVD/SE drive and install it on a SCSI bus along with single-ended devices, you will certainly be wasting the capabilities of the faster device.

Note that all Ultra2 and Ultra3 devices support LVD signaling because that is the only way they can be run at the Ultra2 (40MHz) or Ultra3 (80MHz) speeds. Ultra SCSI (20MHz) or slower devices can support LVD signaling, but in most cases LVD is synonymous with Ultra2 or Ultra3 only.

Table 8.2, shown earlier, lists all the SCSI speeds and maximum lengths for each speed using the supported signaling techniques for that speed.

Because the connectors are the same for SE, HVD, LVD, or multimode SE/LVD devices, and because putting an HVD device on any bus with SE or LVD devices causes damage, it would be nice to be able to tell them apart. One way is to look for a special symbol on the unit; the industry has adopted different universal symbols for single-ended and differential SCSI. Figure 8.3 shows these symbols.

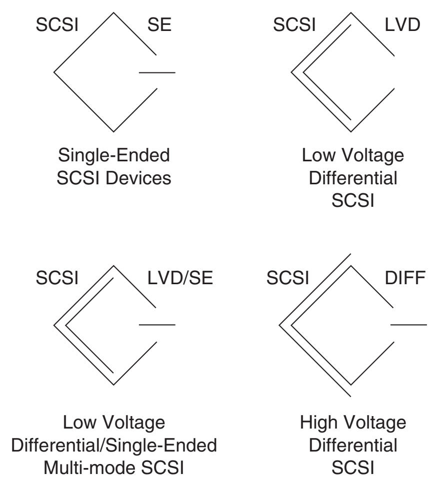

Figure 8.3 Universal symbol icons identifying SE, LVD, multimode LVD/SE, and HVD devices.

If you do not see such symbols, you can tell whether you have a High Voltage Differential device by using an ohmmeter to check the resistance between pins 21 and 22 on the device connector:

- On a single-ended or Low Voltage Differential device, the pins should be tied together and also tied to the ground.
- On a High Voltage Differential device, the pins should be open or have significant resistance between them.

Although you will blow up stuff if you plug HVD devices into LVD or SE buses, this generally should not be a problem because virtually all devices used in the PC environment are SE, LVD, or LVD/SE. HVD has essentially been rendered obsolete because it has been removed from the SCSI standard with Ultra3 SCSI (SPI-3).

SPI-3 or Ultra3 SCSI (Ultra160)

SPI-3, also known as Ultra3 or Ultra160 SCSI, builds on the previous standard and doubles the speed again to Fast-80DT (double transition). This results in a maximum throughput of 160MB/sec. The main features added to SPI-3 (Ultra3) are

- DT (double transition) clocking
- CRC (Cyclic Redundancy Check)
- Domain validation
- Packetization
- Quick Arbitrate and Select (QAS)

Double transition clocking sends data on both the rising and falling edges of the REQ/ACK clock. This enables Ultra3 SCSI to transfer data at 160MB/sec, while still running at a bus clock rate of 40MHz. This mode is defined for 16-bit wide bus use only.

Cyclic Redundancy Checking (CRC) is a form of error checking incorporated into Ultra3 SCSI. Previous versions of SCSI used simple parity checking to detect transmission errors. CRC is a much more robust form of error-detection capability that is far superior for operation at higher speeds.

Domain validation allows better negotiation of SCSI transfer speeds and modes. With prior SCSI versions, when the bus is initialized, the host adapter sends an `INQUIRY` command at the lowest 5MHz speed to each device to determine which data-transfer rate the device can use. The problem is that even though both the host adapter and device might support a given speed, there is no guarantee that the interconnection between the devices will reliably work at that speed. If a problem occurs, the device becomes inaccessible. With domain validation, after a maximum transfer speed is negotiated between the host and the device, it is then tested at that rate. If errors are detected, the rate is stepped down until the connection tests error-free. This is similar to how modems negotiate transmission speeds before communicating and will go a long way toward improve the flexibility and perceived reliability of SCSI.

Packetization is a protocol that enables information to be transferred between SCSI devices in a much more efficient manner. Traditional parallel SCSI uses multiple bus phases to communicate different types of information between SCSI devices: one for command information, two for messages, one for status, and two for data. In contrast, packetized SCSI communicates all this information by using only two phases: one for each direction. This dramatically reduces the command and protocol overhead, especially as higher and higher speeds are used.

Packetized SCSI is fully compatible with traditional parallel SCSI, which means packetized SCSI devices can reside on the same bus as traditional SCSI devices. As long as the host adapter supports the packetization, it can communicate with one device using packets and another using traditional protocol. Not all Ultra3 or Ultra160 SCSI devices include packetization support. Ultra3 devices that support packetization normally are referred to as Ultra160+ SCSI.

Quick Arbitrate and Select (QAS) is a feature in Ultra3 SCSI that reduces arbitration time by eliminating bus free time. QAS enables a device to transfer control of the bus to another device without an intervening BUS FREE phase. SCSI devices that support QAS report that capability in the `INQUIRY` command.

Ultra160 and Ultra160+

Because the five main new features of Ultra3 SCSI are optional, drives could claim Ultra3 capability and not have a consistent level of functionality. To ensure truth in advertising and a minimum level of performance, a group of manufacturers got together and created a substandard within Ultra3 SCSI that requires a minimum set of features. These are called Ultra160 and Ultra160+ because both indicate 160MB/sec throughput. These new substandards are not an official part of SCSI—they are not an official part of the standard. Even so, they do guarantee that certain specifications will be met and certain performance levels will be attained.

Ultra160 is a specific implementation of Ultra3 (SPI-3) SCSI that includes the first three additional features of Ultra3 SCSI:

- Fast-80DT clocking for 160MB/sec operation
- CRC
- Domain validation

Ultra160 SCSI runs in LVD mode and is backward compatible with all Ultra2 SCSI (LVD) devices. The only caveat is that no SE devices must be on the bus. When Ultra2 and Ultra160 (Ultra3) devices are mixed, each device can operate at its full-rated speed independent of the other. The bus will dynamically switch from single- to double-transition mode to support the differences in speeds.

Ultra160+ adds the other two features, ensuring a full implementation of Ultra3:

- Packetization
- Quick Arbitrate and Select

With Ultra160 and Ultra160+, you have a known level of functionality to ensure that a minimum level of performance will be met. Ultra160+ SCSI is the highest-performance PC-level storage interface and is best suited for high-traffic environments, such as high-end network servers or workstations. The adaptability and scalability of the interface enables high performance with high reliability.

SPI-4 or Ultra4 SCSI (Ultra320)

SPI-4, also known as Ultra4 or Ultra320 SCSI, is basically an update on the previous Ultra3 (Ultra160) SCSI. It has all the same features, except it doubles the speed again to Fast-160DT. This results in a maximum throughput of 320MB/sec, the current fastest form of parallel SCSI.

The SPI-4 standard is still in development, although products running at Ultra320 speeds will likely be available before the standard is officially published.

Fiber Channel SCSI

Fiber Channel SCSI is a specification for a serial interface using a fiber channel physical and protocol characteristic, with a SCSI command set. It can achieve 100MB/sec over either fiber or coaxial cable of several kilometers in length. Fiber Channel is designed for long-distance connectivity (such as several kilometers) and connecting multiple systems. Standard parallel SCSI will continue to be the I/O choice for inside the box or external close proximity connectivity for some time to come. Due to compatibility problems between various manufacturers' Fiber Channel devices and the fact that Ultra3 (Ultra160) and Ultra4 (Ultra320) SCSI are significantly faster, Fiber Channel is unlikely to become popular in the PC environment. Ultra160/320 SCSI is also far less expensive to implement and remains backward compatible with Ultra2 SCSI devices.

SCSI Cables and Connectors

The SCSI standards are very specific when it comes to cables and connectors. The most common connectors specified in this standard are the 50-position unshielded pin header connector for internal SCSI connections and the 50-position shielded Centronics latch-style connectors for external connections. The shielded Centronics-style connector also is called Alternative 2 in the official specification. Passive or Active termination (Active is preferred) is specified for both single-ended and differential buses. The 50-conductor bus configuration is defined in the SCSI-2 standard as the A cable.

Older narrow (8-bit) SCSI adapters and external devices use a full-size Centronics-type connector that normally has wire latches on each side to secure the cable connector. Figure 8.4 shows what the low-density, 50-pin SCSI connector looks like.

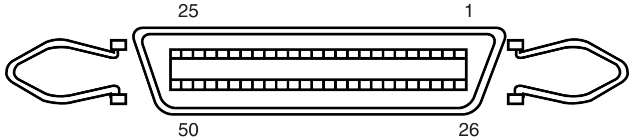

Figure 8.4 Low-density, 50-pin SCSI connector.

The SCSI-2 revision added a high-density, 50-position, D-shell connector option for the A-cable connectors. This connector now is called Alternative 1. Figure 8.5 shows the 50-pin, high-density SCSI connector.

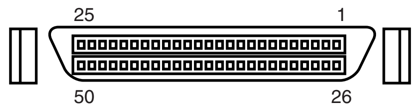

Figure 8.5 High-density, 50-pin SCSI connector.

The Alternative 2 Centronics latch-style connector remains unchanged from SCSI-1. A 68-conductor B-cable specification was added to the SCSI-2 standard to provide for 16- and 32-bit data transfers; the connector, however, had to be used in parallel with an A cable. The industry did not widely accept the B-cable option, which has been dropped from the SCSI-3 standard.

To replace the ill-fated B cable, a new 68-conductor P cable was developed as part of the SCSI-3 specification. Shielded and unshielded high-density D-shell connectors are specified for both the A and P cables. The shielded high-density connectors use a squeeze-to-release latch rather than the wire latch used on the Centronics-style connectors. Active termination for single-ended buses is specified, providing a high level of signal integrity. Figure 8.6 shows the 68-pin, high-density SCSI connector.

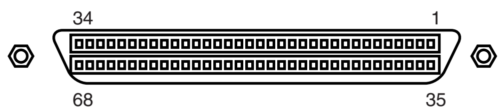

Figure 8.6 High-density, 68-pin SCSI connector.

Drive arrays normally use special SCSI drives with what is called an 80-pin Alternative-4 connector, which is capable of Wide SCSI and also includes power signals. Drives with the 80-pin connector are normally *hot-swappable*—they can be removed and installed with the power on—in drive arrays. The 80-pin Alt-4 connector is shown in Figure 8.7.

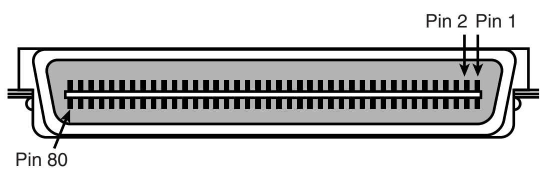

Figure 8.7 80-pin Alt-4 SCSI connector.

Apple and some other nonstandard implementations from other vendors used a 25-pin cable and connector for SCSI devices. They did this by eliminating most of the grounds from the cable, which unfortunately results in a noisy, error-prone connection. I don't recommend using 25-pin cables and connectors; you should avoid them if possible. The connector used in these cases was a standard female DB-25 connector, which looks exactly like a PC parallel port (printer) connector.

Unfortunately, you can damage equipment by plugging printers into DB-25 SCSI connectors or by plugging SCSI devices into DB-25 printer connectors. So, if you use this type of SCSI connection, be sure it is marked well because there is no way to tell DB-25 SCSI from DB-25 parallel printer connectors by looking at them. The DB-25 connector is shown in Figure 8.8.

Again, I recommend you avoid making SCSI connections using this type of cable or connector.

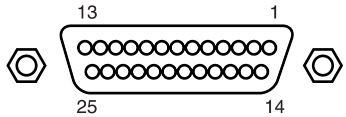

Figure 8.8 DB-25 SCSI connector.

SCSI Cable and Connector Pinouts

The following section details the pinouts of the various SCSI cables and connectors. Two electrically different versions of SCSI exist: single-ended and differential. These two versions are electrically incompatible and must not be interconnected; otherwise, damage will result. Fortunately, very few differential SCSI applications are available in the PC industry, so you will rarely (if ever) encounter one. Within each electrical type (single-ended or differential), there are basically two SCSI cable types:

- A cable (Standard 8-bit SCSI)
- P cable (16-bit Wide SCSI)

The 50-pin A-cable is used in most SCSI-1 and SCSI-2 installations and is the most common cable you will encounter. SCSI-2 Wide (16-bit) applications use a P cable instead, which has 68 pins. You can intermix standard and Wide SCSI devices on a single SCSI bus by interconnecting A and P cables with special adapters. SCSI-3 applications that are 32-bit wide would have used an additional Q cable, but this was finally dropped from the SCSI-3 standard after it was never implemented in actual products.

SCSI cables are specially shielded with the most important high-speed signals carried in the center of the cable and less important, slower ones in two additional layers around the perimeter. A typical SCSI cable is constructed as shown in Figure 8.9.

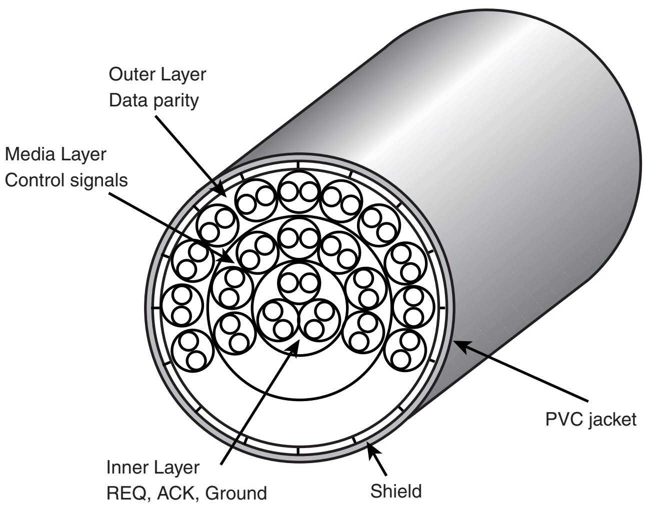

Figure 8.9 Cross section of a typical SCSI cable.

This specialized construction is what makes SCSI cables so expensive, as well as thicker than other types of cables. Note this specialized construction is necessary only for external SCSI cables. Cables used to connect devices inside a shielded enclosure (such as inside a PC) can use much less expensive ribbon cables.

The A cables can have pin-header–type (internal) connectors or external shielded connectors, each with a different pinout. The P cables feature the same connector pinout on either internal or external cable connections.

Single-Ended SCSI Cables and Connectors

The single-ended electrical interface is the most popular type for PC systems. Tables 8.3 and 8.4 show all the possible single-ended cable and connector pinouts. The A cable is available in both internal unshielded and external shielded configurations. A hyphen preceding a signal name indicates the signal is Active Low. The RESERVED lines have continuity from one end of the SCSI bus to the other. In an A cable bus, the RESERVED lines should be left open in SCSI devices (but may be connected to ground) and are connected to ground in the bus terminator assemblies. In the P and Q cables, the RESERVED lines are left open in SCSI devices and in the bus terminator assemblies.

IBM used the SCSI interface in virtually all PS/2 systems introduced after 1990. These systems use a Micro-Channel SCSI adapter or have the SCSI Host Adapter built into the motherboard. In either case, IBM's SCSI interface uses a special 60-pin, mini-Centronics–type external shielded connector that is unique in the industry. A special IBM cable is required to adapt this connector to the standard 50-pin

Centronics-style connector used on most external SCSI devices. The pinout of the IBM 60-pin, mini-Centronics–style external shielded connector is shown in Table 8.5. Notice that although the pin arrangement is unique, the pin-number–to–signal designations correspond with the standard unshielded internal pin header type of SCSI connector. IBM has discontinued this design in all its systems because after the PS/2 series, all have used conventional SCSI connectors.

The P cable (single-ended) and connectors are used in 16-bit Wide SCSI-2 applications (see Table 8.6 for the pinout).

High Voltage Differential SCSI Signals

High Voltage Differential SCSI is not normally used in a PC environment but is very popular with minicomputer installations because of the very long bus lengths that are allowed. This has changed with the introduction of Low Voltage Differential signaling for SCSI, bringing the benefits of differential signaling to lower-end and more mainstream SCSI products.

Differential signaling uses drivers on both the initiator and target ends of the bus and makes each signal work in a push/pull arrangement, rather than a signal/ground arrangement as with standard single-ended SCSI. This enables much greater cable lengths and eliminates some of the problems with termination.

Almost all PC peripherals produced since the beginning of SCSI have been SE types. These are incompatible with HVD devices, although HVD devices can be used on an SE bus with appropriate (and expensive) adapters. The LVD devices, on the other hand, can be used on an SE bus if they are multimode devices, in which case they switch into SE mode. If all devices—including the host adapter—support LVD mode, all the devices switch into that mode and much longer cable lengths and higher speeds can be used. The normal limit for an SE SCSI bus is 1.53 meters maximum (about 5–10 feet) and up to 20MHz. If run in LVD mode, the maximum bus length goes up to 12 meters (about 40 feet) and speeds can go up to 80MHz. HVD SCSI supports bus lengths of up to 25 meters (about 80 feet).

Note that almost all modern SCSI hard disks are Ultra2 or Ultra3 devices, which means by default they are also LVD or multimode LVD/SE devices.

Expanders

SCSI expanders separate a SCSI bus into more than one physical segment, each of which can have the full SCSI cable length for that type of signaling. They provide a complete regeneration of the SCSI bus signals, allowing greater cable lengths and incompatible devices to essentially share the same bus. An expander also can be used to separate incompatible parts of a SCSI bus—for example, to keep SE and HVD SCSI devices in separate domains.

Expanders are transparent to the software and firmware on the bus, and they don't take up a device ID. They are normally capable of providing termination if located at the end of a bus segment, or they can have termination disabled if they are in the middle of a bus segment.

Because of their expense, expanders are not normally used except in extreme situations in which no other alternative remains. In most cases it is better to stick within the recommended cable and bus length requirements and keep incompatible devices, such as HVD devices, off a standard SE or LVD bus.

Termination

Because a SCSI bus carries high-speed electrical signals, it can be affected by electrical reflections that might occur within any transmission line system. A terminator is designed to minimize the potential for reflections or noise on the bus, as well as to create the proper load for the bus transmitter circuits. Terminators are placed at each end of the bus to minimize these problems.

Despite the simple rules that only two terminators must be on the bus and they must be at each end, I still see improper termination as the most common cause of problems in SCSI installations.

Several kinds of SCSI terminators are available, dependent on the bus signaling and speed requirements:

- Passive
- Active (also called Alternative 2)
- Forced Perfect Termination (FPT): FPT-3, FPT-18, and FPT-27

- HVD termination
- LVD termination

The first three are used on single-ended SCSI buses only. Passive terminators use a passive network of 220ohm and 330ohm resistors to control bus termination. They should be used only in narrow (8-bit) SCSI buses running at 5MHz. Passive terminators allow signal fluctuations in relation to the terminator power signal on the bus. Usually, passive terminating resistors suffice over short distances, such as 2 or 3 feet, but for longer distances or higher speeds, active termination is a real advantage. Active termination is required with Fast SCSI.

Figure 8.10 shows the schematic of a typical passive terminator.

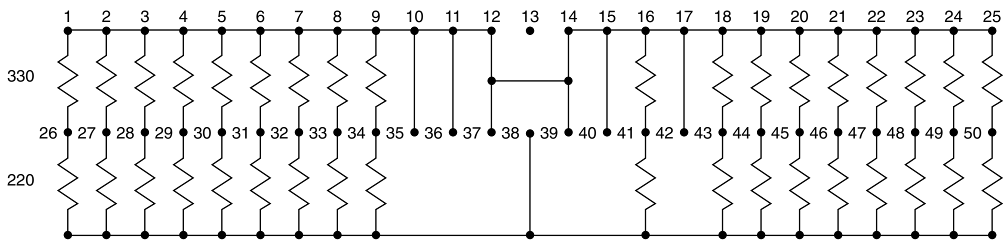

Figure 8.10 Passive SCSI terminator schematic.

Active terminators use built-in voltage regulator ICs combined with 110ohm resistors. An active terminator actually has one or more voltage regulators to produce the termination voltage, rather than resistor voltage dividers alone. This arrangement helps ensure that the SCSI signals always are terminated to the correct voltage level. Active terminators often have some sort of LED indicating the termination activity. The SCSI-2 specification recommends active termination on both ends of the bus and requires active termination whenever Fast or Wide SCSI devices are used. Most high-performance host adapters have an “auto-termination” feature, so if it is the end of a chain, it terminates itself. Figure 8.11 shows a typical active terminator.

A variation on active termination is available for single-ended buses: *forced perfect termination (FPT)*. Forced perfect termination is an even better form of active termination, in which diode clamps are added to eliminate signal overshoot and undershoot. The trick is that instead of clamping to +5 and ground, these terminators clamp to the output of two regulated voltages. This arrangement enables the clamping diodes to eliminate signal overshoot and undershoot, especially at higher signaling speeds and over longer distances. Forced perfect termination is technically not found in the SCSI specifications but is the superior type of termination for single-ended applications that experience high levels of electrical noise. Figure 8.12 shows the schematic of a typical FPT-18 type terminator (18 lines forced perfect, designed for 50-pin connections).

FPT terminators are available in several versions. FPT-3 and FPT-18 versions are available for 8-bit standard SCSI, whereas the FPT-27 is available for 16-bit (Wide) SCSI. The FPT-3 version forces perfect the three most highly active SCSI signals on the 8-bit SCSI bus, whereas the FPT-18 forces perfect all the SCSI signals on the 8-bit bus except grounds. FPT-27 also forces perfect all the 16-bit Wide SCSI signals except grounds.

HVD buses require HVD terminators, constructed using a passive network of 330ohm/150ohm/330ohm resistors. The only choice there is that the terminator matches your cable or device connection.

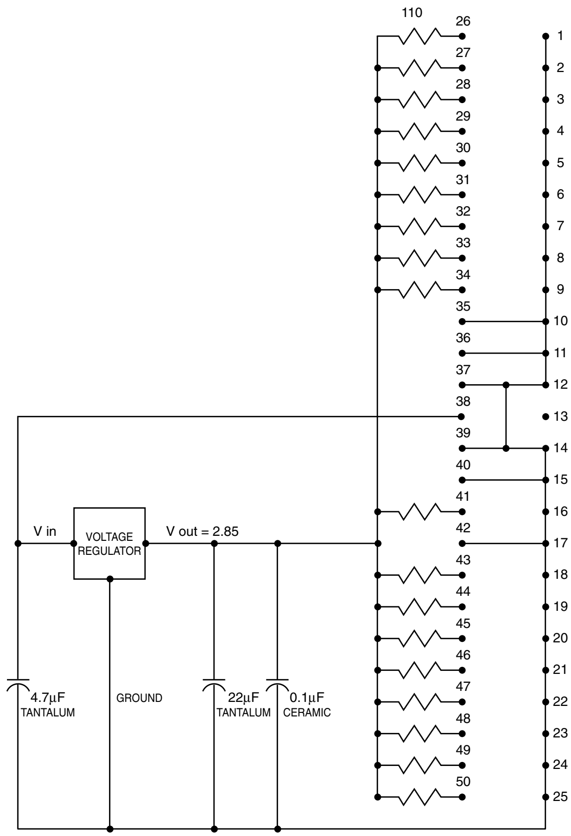

Figure 8.11 Active SCSI terminator schematic.

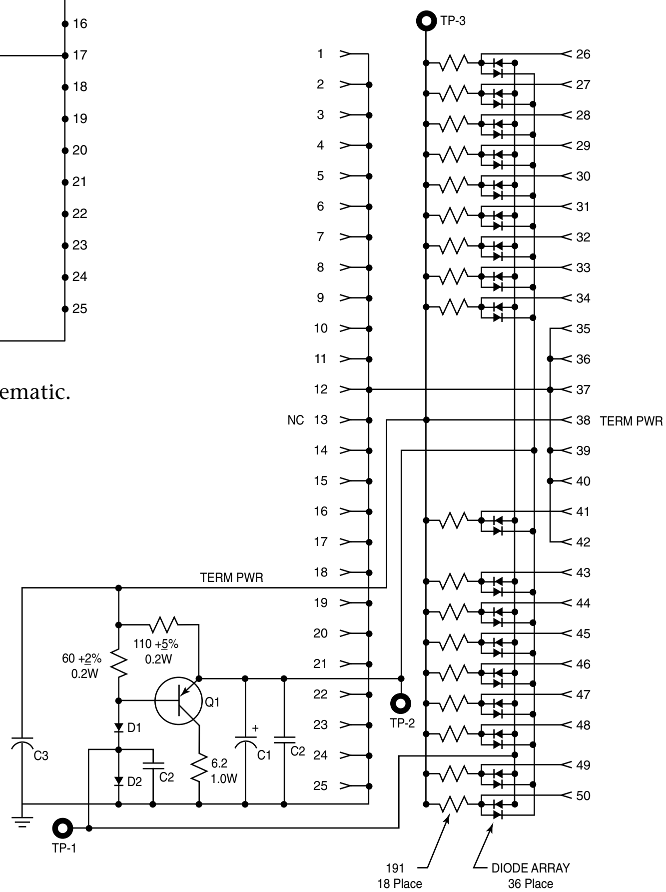

Figure 8.12 FPT SCSI terminator schematic.

The same is true for Low Voltage Differential buses. They require LVD terminators for the bus to function properly. One twist is that special LVD/SE (active) multimode terminators are available. These function as LVD types on an LVD bus and as active types on an SE bus. Note that if any SE devices are on the bus, it functions in SE mode and never uses LVD mode, severely limiting bus length and performance. If any SE-only terminators or SE devices are on the bus, the bus defaults into SE mode.

▶▶ See the next section, "SCSI Drive Configuration," p. 534.

Note

Several companies make high-quality terminators for the SCSI bus, including Aeronics and the Data Mate division of Methode. Both companies make a variety of terminators. Aeronics is well noted for some unique FPT versions that are especially suited to problem configurations that require longer cable runs or higher signal integrity. One of the best investments you can make in any SCSI installation is in high-quality cables and terminators. Contact information for both of these companies is in the Vendor List on the CD.

Special terminators also are required for LVD and HVD SCSI, so if you are using those interfaces, make sure your terminators are compatible.

With LVD or HVD buses, you don't have much choice in terminator types, but for single-ended (SE) buses, you have at least three choices.

Tip

My recommendation is to *never* use passive terminators; instead, use only active or FPT. If you want the best in reliability and integrity, choose FPT. The best rule for terminators as well as for cables is to get the best you can.

SCSI Drive Configuration

SCSI drives are not too difficult to configure, but they are more complicated than IDE drives. The SCSI standard controls the way the drives must be set up. You need to set up two or three items when you configure a SCSI drive:

- SCSI ID setting (0–7 or 0–15)
- Terminating resistors

The SCSI ID setting is very simple. Up to 7 SCSI devices can be used on a single narrow SCSI bus or up to 15 devices on a wide SCSI bus, and each device must have a unique SCSI ID address. There are 8 or 16 addresses respectively, and the host adapter takes 1 address, so the rest are free for up to 7 or 15 SCSI peripherals. Most SCSI host adapters are factory-set to ID 7 or 15, which is the highest priority ID. All other devices must have unique IDs that do not conflict with one another. Some host adapters boot only from a hard disk set to a specific ID. Older Adaptec host adapters required the boot hard disk to be ID 0; newer ones can boot from any ID.

Setting the ID usually involves changing jumpers on the drive. If the drive is installed in an external chassis, the chassis might have an ID selector switch that is accessible at the rear. This selector makes ID selection a simple matter of pressing a button or rotating a wheel until the desired ID number appears. If no external selector is present, you must open the external device chassis and set the ID via the jumpers on the drive.

Three jumpers are required to set the SCSI ID; the particular ID selected actually is derived from the binary representation of the jumpers themselves. One example is setting all three ID jumpers off results in a binary number of 000b, which translates to an ID of 0. A binary setting of 001b equals ID 1; 010b equals 2; 011b equals 3; and so on. (Notice that as I list these values, I append a lowercase b to indicate binary numbers.)

Unfortunately, the jumpers can appear either forward or backward on the drive, depending on how the manufacturer set them up. To keep things simple, I have recorded all the various ID jumper settings in the following tables. Table 8.7 shows the settings for drives that order the jumpers with the most significant bit (MSB) to the left; Table 8.8 shows the settings for drives that have the jumpers ordered so that the MSB is to the right.

Table 8.7 SCSI ID Jumper Settings with the Most Significant Bit to the Left

SCSI	ID	Jumper	Settings
0	0	0	0
1	0	0	1
2	0	1	0
3	0	1	1
4	1	0	0
5	1	0	1
6	1	1	0
7	1	1	1

1 = Jumper On; 0 = Jumper Off

Table 8.8 SCSI ID Jumper Settings with the Most Significant Bit to the Right

SCSI	ID	Jumper	Settings
0	0	0	0
1	1	0	0
2	0	1	0
3	1	1	0
4	0	0	1
5	1	0	1
6	0	1	1
7	1	1	1

1 = Jumper On; 0 = Jumper Off

SCSI termination is very simple. Termination is required at both ends of the bus; there are no exceptions. If the host adapter is at one end of the bus, it must have termination enabled. If the host adapter is in the middle of the bus, and if both internal and external bus links are present, the host adapter must have its termination disabled, and the devices at each end of the bus must have terminators installed. Unfortunately, the majority of problems I see with SCSI installations are the result of improper termination.

Figure 8.13 shows a representation of a SCSI bus with several devices attached. In this case, the host adapter is at one end of the bus and a CD-ROM drive is at the other. For the bus to work properly, those devices must be terminated, whereas the others do not.

When installing an external SCSI device, you usually will find the device in a storage enclosure with both input and output SCSI connectors, so you can use the device in a daisy-chain. If the enclosure is at the end of the SCSI bus, an external terminator module most likely will have to be plugged into the second (outgoing) SCSI port to provide proper termination at that end of the bus (see Figure 8.14).

External terminator modules are available in a variety of connector configurations, including pass-through designs, which are necessary if only one port is available. Pass-through terminators also are commonly used in internal installations in which the device does not have built-in terminating resistors. Many hard drives use pass-through terminators for internal installations to save space on the logic-board assembly (see Figure 8.15).

The pass-through models are required when a device is at the end of the bus and only one SCSI connector is available.

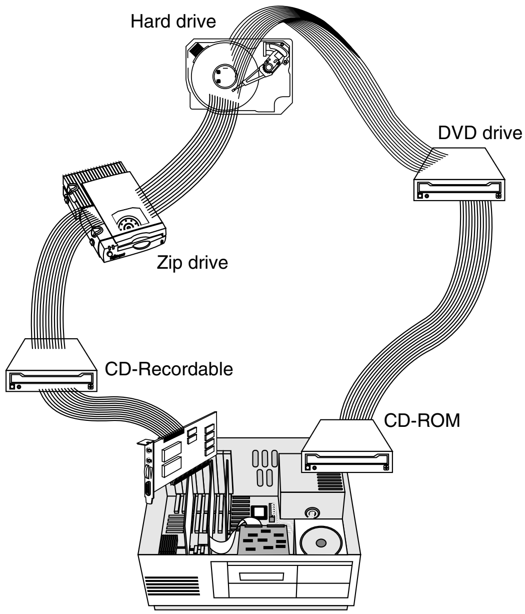

Figure 8.13 SCSI bus daisy-chain connections; the first and last devices must be terminated.

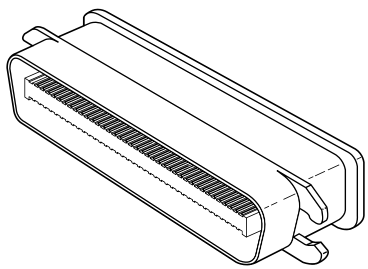

Figure 8.14 External SCSI device terminator.

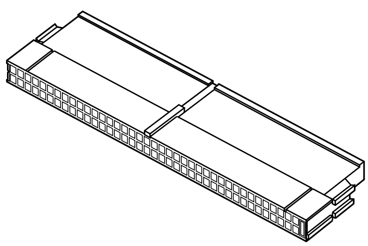

Figure 8.15 Internal pin-header connector pass-through SCSI terminator.

Other configuration items on a SCSI drive can be set via jumpers. Following are several of the most common additional settings that you will find:

- Start on Command (delayed start)
- SCSI Parity
- Terminator Power
- Synchronous Negotiation

These configuration items are described in the following sections.

Start on Command (Delayed Start)

If you have multiple drives installed in a system, it is wise to set them up so that not all the drives start to spin immediately when the system is powered on. A hard disk drive can consume three or four times more power during the first few seconds after power-on than during normal operation. The motor requires this additional power to get the platters spinning quickly. If several drives are drawing all this power at the same time, the power supply can be overloaded, which can cause the system to hang or have intermittent startup problems.

Nearly all SCSI drives provide a way to delay drive spinning so this problem does not occur. When most SCSI host adapters initialize the SCSI bus, they send out a command called Start Unit to each of the ID addresses in succession. By setting a jumper on the hard disk, you can prevent the disk from spinning until it receives the Start Unit command from the host adapter. Because the host adapter sends this command to all the ID addresses in succession, from the highest priority address (ID 7) to the lowest (ID 0), the higher priority drives can be made to start first, with each lower priority drive spinning up sequentially. Because some host adapters do not send the Start Unit command, some drives might simply delay spin-up for a fixed number of seconds rather than wait for a command that never will arrive.

If drives are installed in external chassis with separate power supplies, you need not implement the delayed-start function. This function is best applied to internal drives that must be run from the same power supply that runs the system. For internal installations, I recommend setting Start on Command (delayed start) even if you have only one SCSI drive; this setting eases the load on the power supply by spinning the drive up after the rest of the system has full power. This method is especially good for portable systems and other systems in which the power supply is limited.

SCSI Parity

SCSI Parity is a limited form of error checking that helps ensure that all data transfers are reliable. Virtually all host adapters support SCSI parity checking, so this option should be enabled on every device. The only reason it exists as an option is that some older host adapters do not work with SCSI parity, so the parity must be turned off.

Terminator Power

The terminators at each end of the SCSI bus require power from at least one device on the bus. In most cases, the host adapter supplies this terminator power; in some cases, however, it does not. For example, parallel port SCSI host adapters typically do not supply terminator power. It is not a problem if more than one device supplies terminator power because each source is diode-protected. For simplicity's sake, many people often configure all devices to supply terminator power. If no device supplies terminator power, the bus is not terminated correctly and will not function properly.

SCSI Synchronous Negotiation

The SCSI bus can run in two modes: asynchronous (the default) and synchronous. The bus actually switches modes during transfers through a protocol called *synchronous negotiation*. Before data is transferred across the SCSI bus, the sending device (called the *initiator*) and the receiving device (called the *target*) negotiate how the transfer will take place. If both devices support synchronous transfers, they will discover this fact through the negotiation, and the transfer will take place at the faster synchronous rate.

Unfortunately, some older devices do not respond to a request for synchronous transfer and can actually be disabled when such a request is made. For this reason, both host adapters and devices that support synchronous negotiation often have a jumper that can be used to disable this negotiation so it can work with older devices. By default, all devices today should support synchronous negotiation, and this function should be enabled.

Plug-and-Play SCSI

Plug-and-Play (PnP) SCSI was originally released in April 1994. This specification enables SCSI device manufacturers to build PnP peripherals that are automatically configured when used with a PnP operating system. This enables you to easily connect or reconfigure external peripherals, such as hard disk drives, backup tapes, and CD-ROMs.

To connect SCSI peripherals to the host PC, the specification requires a PnP SCSI host adapter, such as PnP ISA or PCI. PnP add-in cards enable a PnP operating system to automatically configure software device drivers and system resources for the host bus interface.

The PnP SCSI specification version 1.0 includes these technical highlights:

- A single cable connector configuration
- Automatic termination of the SCSI bus
- SCAM (SCSI Configured AutoMagically*) automatic ID assignment
- Full backward compatibility of PnP SCSI devices with the installed base of SCSI systems

Note

"AutoMagically"is not a misspelling. The word is actually used in the official name for the specification, which the X3T9.2 committee designated X3T9.2/93-109r5.

This should go a long way in making SCSI easier to use for the normal user.

Each SCSI peripheral you add to your SCSI bus (other than hard disk drives) requires an external driver to make the device work. Hard disks are the exception; driver support for them normally is provided as part of the SCSI host adapter BIOS. These external drivers are specific not only to a particular device, but also to the host adapter.

Recently, two types of standard host adapter interface drivers have become popular, greatly reducing this problem. By having a standard host adapter driver to write to, peripheral makers can more quickly create new drivers that support their devices and then talk to the universal host adapter driver. This arrangement eliminates dependence on one particular type of host adapter. These primary or universal drivers link the host adapter and operating system.

The Advanced SCSI Programming Interface (ASPI) currently is the most popular universal driver, with most peripheral makers writing their drivers to talk to ASPI. The *A* in ASPI used to stand for Adaptec, the company that introduced it, but other SCSI device vendors have licensed the right to use ASPI with their products. DOS does not support ASPI directly, but it does when the ASPI driver is loaded. Windows 9x/Me, Windows NT/2000, and OS/2 2.1 and later versions provide automatic ASPI support for several SCSI host adapters.

Future Domain and NCR have created another interface driver called the Common Access Method (CAM). CAM is an ANSI-approved protocol that enables a single driver to control several host adapters. In addition to ASPI, OS/2 2.1 and later versions currently offer support for CAM. Future Domain also provides a CAM-to-ASPI converter in the utilities that go with its host adapters.

SCSI Configuration Troubleshooting

When you are installing a chain of devices on a single SCSI bus, the installation can get complicated very quickly. If you have a problem during installation, check these items first:

- Make sure you are using the latest BIOS from your motherboard manufacturer. Some have had problems with their PCI bus slots not working properly.
- Make sure that all SCSI devices attached to the bus are powered on.
- Make sure all SCSI cables and power cables are properly connected. Try removing and reseating all the connectors to be sure.
- Check that the host adapter and each device on each SCSI bus channel have a unique SCSI ID setting.
- Make sure the SCSI bus is terminated properly. Remember there should be only two terminators on the bus, one at each end. All other termination should be removed or disabled.
- If your system BIOS setup has settings for controlling PCI bus configuration, make sure the PCI slot containing the SCSI adapter is configured for an available interrupt. If your system is Plug and Play, use the Windows Device Manager to check and possibly change the resource configuration.
- Make sure the host adapter is installed in a PCI slot that supports bus mastering. Some older motherboards did not allow bus mastering to work in all PCI slots. Check your motherboard documentation and try moving the SCSI host adapter to a different PCI slot.
- If you have a SCSI hard disk installed and your system will not boot from the SCSI drive, there can be several causes for this problem. Note that if both SCSI and non-SCSI disk drives are installed in your computer, in almost all cases the non-SCSI drive will be the boot device. If you want to boot from a SCSI drive, check the boot sequence configuration in your BIOS. If your system allows it, change the boot sequence to allow SCSI devices to boot first. If not, try removing the non-SCSI drives from your system.

If the system has only SCSI disk drives and it still won't boot, check the following items:

- Make sure your computer's BIOS Setup drive configuration is set to "No Drives Installed." The PC BIOS supports only ATA (IDE) drives; by setting this to no drives, the system will then try to boot from another device, such as SCSI.
- Make sure the drive is partitioned and that a primary partition exists. Use FDISK from DOS or Windows to check.
- Make sure the boot partition of the boot hard disk is set to active. This can be checked or changed with the FDISK program.
- Finally as a last resort, you can try backing up all data on the SCSI hard disk, and then perform a low-level format with the Format utility built into or included with the host adapter.

Here are some tips for getting your setup to function quickly and efficiently:

- *Start by adding one device at a time.* Rather than plugging numerous peripherals into a single SCSI card and then trying to configure them at the same time, start by installing the host adapter and a single hard disk. Then, you can continue installing devices one at a time, checking to make sure that everything works before moving on.
- *Keep good documentation.* When you add a SCSI peripheral, write down the SCSI ID address and any other switch and jumper settings, such as SCSI Parity, Terminator Power, and Delayed or Remote Start. For the host adapter, record the BIOS addresses, Interrupt, DMA channel, and I/O Port addresses used by the adapter, and any other jumper or configuration settings (such as termination) that might be important to know later.
- *Use proper termination.* Each end of the bus must be terminated, preferably with active or Forced Perfect terminators. If you are using any Fast SCSI-2 device, you must use active terminators rather than the cheaper passive types. Even with standard (slow) SCSI devices, active termination is highly recommended. If you have only internal or external devices on the bus, the host adapter and last device on the chain should be terminated. If you have external and internal devices on the chain, you generally will terminate the first and last of these devices but not the SCSI host adapter (which is in the middle of the bus).
- *Use high-quality shielded SCSI cables.* Make sure your cable connectors match your devices. Use high-quality shielded cables, and observe the SCSI bus-length limitations. Use cables designed for SCSI use, and, if possible, stick to the same brand of cable throughout a single SCSI bus. Different brands of cables have different impedance values; this situation sometimes causes problems, especially in long or high-speed SCSI implementations.

Following these simple tips will help minimize problems and leave you with a trouble-free SCSI installation.

SCSI Versus IDE

When you compare the performance and capabilities of IDE and SCSI interfaced drives, you need to consider several factors. These two types of drives are the most popular drives used in PC systems today, and a single manufacturer might make identical drives in both interfaces. Deciding which drive type is best for your system is a difficult decision that depends on many factors.

In most cases, you will find that an IDE drive using the same head-disk assembly as a SCSI drive from the same manufacturer will perform about the same or outperform the equivalent SCSI drive at a given task or benchmark. This is mainly true when using a single disk drive with a single-user operating system, such as Windows 9x/Me. More powerful operating systems, such as Windows NT or Windows 2000, can more effectively use the command queuing and other features of SCSI, thus improving performance over IDE—especially when supporting multiple drives.

It is interesting to see that SCSI really evolved from IDE, or you could say that both evolved from the ST-506/412 and ESDI interfaces that were once used.

SCSI Hard Disk Evolution and Construction

SCSI is not a disk interface, but a bus that supports SCSI bus interface adapters connected to disk and other device controllers. The first SCSI drives for PCs were standard ST-506/412 or ESDI drives with a separate SCSI bus interface adapter (sometimes called a bridge controller) that converted the ST-506/412 or ESDI interfaces to SCSI. This interface originally was in the form of a secondary logic board, and the entire assembly often was mounted in an external case.

The next step was to build the SCSI bus interface "converter" board directly into the drive's own logic board. Today, we call these drives embedded SCSI drives because the SCSI interface is built in.

At that point, there was no need to conform to the absolute specifications of ST-506/412 or ESDI on the internal disk interface because the only other device the interface ever would have to talk to was built in as well. Thus, the disk-interface and controller-chipset manufacturers began to develop more customized chipsets that were based on the ST-506/412 or ESDI chipsets already available but offered more features and higher performance.

Today, if you look at a typical SCSI drive, you often can identify the chip or chipset that serves as the disk controller on the drive as being exactly the same kind that would be used on an ST-506/412 or ESDI controller, or as some evolutionary customized variation thereof.

Consider some examples. An ATA IDE drive must fully emulate the system-level disk-controller interface introduced with the Western Digital WD1003 controller series IBM used in the AT. These drives must act as though they have a built-in ST-506/412 or ESDI controller; in fact, they actually do. Most of these built-in controllers have more capabilities than the original WD1003 series (usually in the form of additional commands), but they must at least respond to all the original commands that were used with the WD1003.

If you follow the hard-drive market, you usually will see that drive manufacturers offer most of their newer drives in both ATA-IDE and SCSI versions. In other words, if a manufacturer makes a particular 20GB IDE drive, you invariably see that the company also makes a SCSI model with the same capacity and specifications, which uses the same head disk assembly (HDA) and even looks the same as the IDE version. If you study these virtually identical drives, the only major difference you will find is the additional chip on the logic board of the SCSI version, called a SCSI Bus Adapter Chip (SBIC).

Figures 8.16 and 8.17 show the logic-block diagrams of an ATA/IDE and a SCSI drive from the same manufacturer. These drives use the same HDA; they differ only in their logic boards, and even the logic boards are the same except for the addition of an SBIC on the SCSI drive's logic board.

Notice that even the circuit designs of these two drives are almost identical. Both drives use an LSI (large scale integrated circuit) chip called the WD42C22 Disk Controller and Buffer Manager chip. In the ATA drive, this chip is connected through a DMA control chip directly to the AT bus. In the SCSI version, a WD33C93 SCSI bus interface controller chip is added to interface the disk-controller logic to the SCSI bus. In fact, the logic diagrams of these two drives differ only in the fact that the SCSI version has a complete subset of the ATA drive, with the SCSI bus interface controller logic added. This essentially is a very condensed version of the separate drive and bridge controller setups that were used in the early days of PC SCSI.

◀◀ See "DMA Transfer Modes," p. 504.

To top off this example, study the logic diagram in Figure 8.18 for the WD 1006V-MM1, which is an ST-506/412 controller.

You can clearly see that the main LSI chip onboard is the same WD42C22 disk controller chip used in the IDE and SCSI drives. Here is what the technical reference literature says about that chip:

> *The WD42C22 integrates a high performance, low cost Winchester controller's architecture. The WD42C22 integrates the central elements of a Winchester controller subsystem such as the host interface, buffer manager, disk formatter/controller, encoder/decoder, CRC/ECC (Cyclic Redundancy Check/Error Correction Code) generator/checker, and drive interface into a single 84-pin PQFP (Plastic Quad Flat Pack) device.*

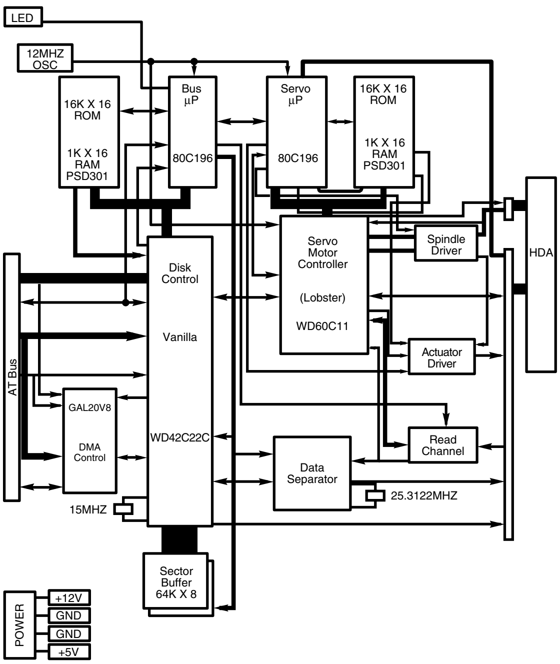

Figure 8.16 Typical ATA-IDE drive logic-board block diagram.

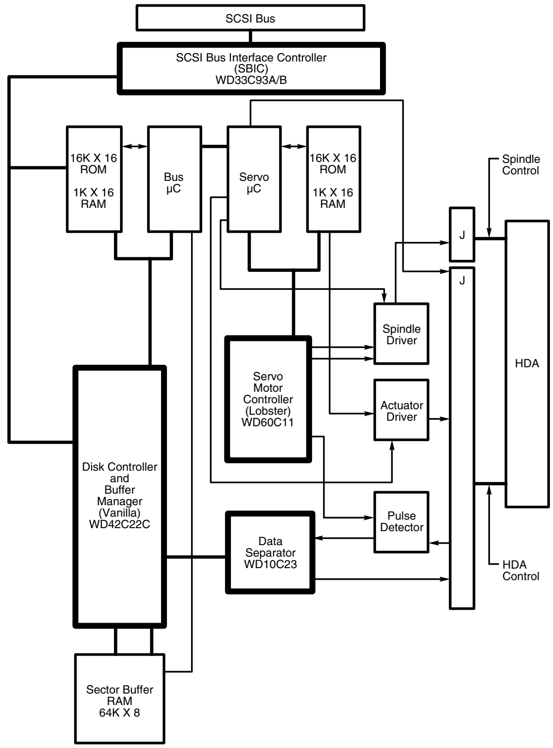

Figure 8.17 Typical SCSI drive logic board block diagram.

The virtually identical design of ATA-IDE and SCSI drives is not unique to Western Digital. Most drive manufacturers design their ATA-IDE and SCSI drives the same way, often using these very same WD chips, and disk controller and SCSI bus interface chips from other manufacturers. You now should be able to understand that most SCSI drives are "regular" ATA-IDE drives with SCSI bus logic added. This fact will come up again later in this chapter in the section "SCSI Versus IDE: Advantages and Limitations," which discusses performance and other issues differentiating these interfaces.

For another example, I have several old IBM 320MB and 400MB embedded SCSI-2 hard disks; each of these drives has onboard a WD-10C00 Programmable Disk Controller in the form of a 68-pin Plastic Leaded Chip Carrier (PLCC) chip. The technical literature states:

> *This chip supports ST412, ESDI, SMD and Optical interfaces. It has 27Mbit/sec maximum transfer rate and an internal, fully programmable 48- or 32-bit ECC, 16-bit CRC-CCITT or external user defined ECC polynomial, fully programmable sector sizes, and 1.25 micron low power CMOS design.*

In addition, these particular embedded SCSI drives include the 33C93 SCSI Bus Interface Controller chip, which also is used in the other SCSI drive I mentioned. Again, there is a distinctly separate disk controller, and the SCSI interface is added on.

So again, most embedded SCSI drives have a built-in disk controller (usually based on previous ST-506/412 or ESDI designs) and additional logic to interface that controller to the SCSI bus (a built-in bridge controller, if you like). Now think about this from a performance standpoint. If virtually all SCSI drives really are ATA-IDE drives with a SCSI Bus Interface Controller chip added, what conclusions can you draw?

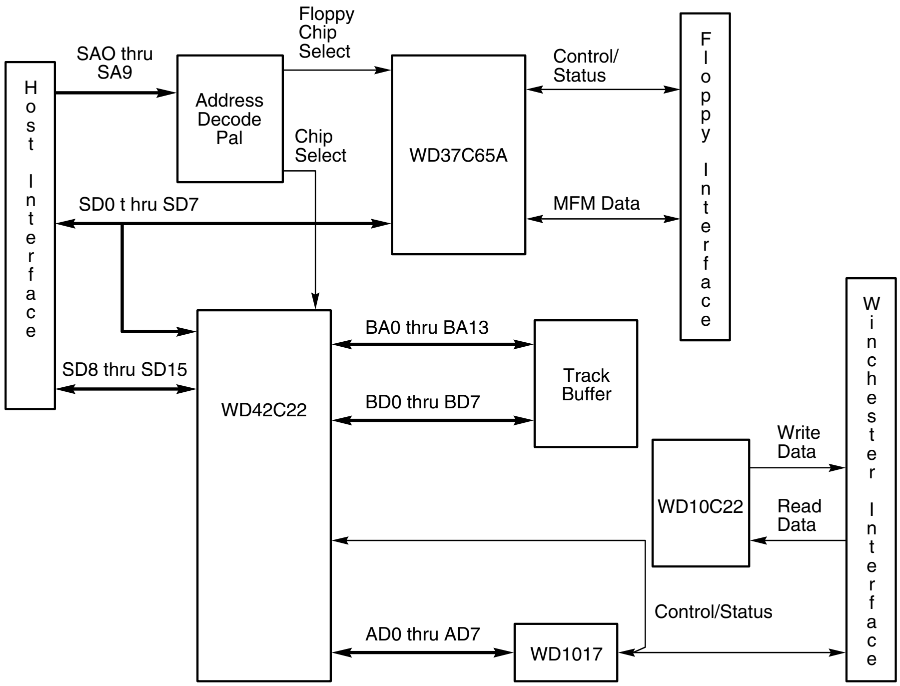

Figure 8.18 Western Digital WD1006V-MM1 ST-506/412 Disk Controller block diagram.

First, no drive can perform sustained data transfers faster than the data can actually be read from the disk platters. In other words, the HDA limits performance to whatever it is capable of achieving. Drives can transmit data in short bursts at very high speeds because they often have built-in cache or read-ahead buffers that store data. Many of the newer high-performance SCSI and ATA-IDE drives have 1MB or more of cache memory onboard. No matter how big or intelligent the cache is, however, sustained data transfer is still limited by the HDA.

◀◀ See "ATA IDE," p. 480.

Data from the HDA must pass through the disk controller circuits, which, as you have seen, are virtually identical between similar SCSI and ATA-IDE drives. In the ATA-IDE drive, this data then is presented directly to the system bus. In the SCSI drive, however, the data must pass through a SCSI bus interface adapter on the drive, travel through the SCSI bus, and then pass through another SCSI bus interface controller in the SCSI host adapter card in your system. The longer route a SCSI transfer must take makes this type of transfer slower than the much more direct ATA-IDE transfer.

The conventional wisdom has been that SCSI always is much faster than IDE; unfortunately, this wisdom is usually wrong. This incorrect conclusion was derived by looking at the raw SCSI and ISA bus performance capabilities. A 16-bit Ultra3 SCSI drive can transfer data at a claimed 160MB/sec, whereas an Ultra-ATA/66 IDE drive can transfer data at 66MB/sec. Based on these raw transfer rates, SCSI seems to be faster, but the raw transfer rate of the bus is not the limiting factor. As discussed previously, the actual HDA and disk-controller circuitry place limits on this performance. The key figure to check is what is reported as the internal transfer rate for the drive. For example, here are the specs on two similar drives (one IDE and one SCSI):

IDE Drive	
Drive	IBM Deskstar 18GXP ATA
Interface	Ultra-ATA/66
Platters	5
Data heads	10
Capacity	18.0GB
Recording density	218.6KB/inch
Rotational speed	7,200rpm
Internal cache buffer	2MB
Interface transfer rate	up to 66.7MB/sec
Media transfer rate	27.9MB/sec max.
Sustained data transfer rate	10.7–17.9MB/sec max.
Average sustained transfer rate	14.3MB/sec

SCSI Drive	
Drive	IBM Ultrastar 18ES SCSI
Interface	Ultra2/Wide SCSI
Platters	5
Data heads	10
Capacity	18.2GB
Recording density	220KB/inch
Rotational speed	7,200rpm
Internal cache buffer	2MB
Interface transfer rate	up to 80MB/sec
Media transfer rate	30.5MB/sec maximum
Sustained data transfer rate	12.7–20.2MB/sec
Average sustained transfer rate	16.45MB/sec

Note that although the SCSI drive can claim a much higher external transfer rate of 80MB/sec as compared to the ATA drive's 66.7MB/sec, in actuality these drives are almost identical performers. The real specs to look at are in the last two lines of the tables, which detail how fast data can actually be read from the drive. In particular, the sustained transfer rates are the true transfer rates for reading data from these drives; as you can see, they are very close indeed. The true transfer rate of a drive is mainly influenced by the rotational speed, track density, and things such as internal buffers or caches.

Then you have to factor in that the SCSI drive listed earlier would cost 50%–100% more than the IDE counterpart. Not to mention the cost of springing for an Ultra2/Wide host adapter to plug the drive into. Decent SCSI adapters, especially Wide SCSI versions, can easily run $300 or more. When you consider that the UltraATA interface is built into most modern motherboards for free, you can see that, depending on your needs, spending a ton of extra cash for SCSI can be a significant waste of money.

Now to present the counterpoint: Although these two drives are basically equivalent, the ATA version was one of the top ATA drives offered by IBM at the time, whereas the SCSI drive listed earlier was only a middle-of-the-pack performer. IBM and others make SCSI drives that have rotational speeds of 10,000rpm, increased track density, and larger buffers. Of course, these drives cost even more. So the bottom line is that if you must have the absolute best performing drives, by all means get the top-of-the-line SCSI drives and Ultra SCSI Wide adapters. However, if you want something that is literally 1/3 to 1/4 the cost and 3/4 or more the performance, stick with IDE.

Performance

ATA IDE drives currently are used in most PC configurations on the market because the cost of an IDE-drive implementation is low and the performance capabilities are high. In comparing any given IDE and SCSI drive for performance, you have to look at the capabilities of the HDAs that are involved.

To minimize the variables in this type of comparison, it is easiest to compare IDE and SCSI drives from the same manufacturer that also use the identical HDA. You will find that in most cases, a drive manufacturer makes a given drive available in both IDE and SCSI forms. For example, most hard drive companies make similar SCSI and IDE drives that use identical HDAs and that differ only in the logic board. The IDE version has a logic board with a built-in disk controller and a direct AT bus interface. The SCSI version has the same built-in disk controller and bus interface circuits and also a SBIC chip. The SBIC chip is a SCSI adapter that places the drive on the SCSI bus. What you will find, in essence, is that virtually all SCSI drives actually are IDE drives with the SBIC chip added.

The HDAs in these sample drives are capable of transferring data at a sustained rate of up to 8MB/sec or more. Because the SCSI version always has the additional overhead of the SCSI bus to go through, in almost all cases the directly attached IDE version performs slightly faster.

SCSI Versus IDE: Advantages and Limitations

Modern operating systems are multitasking, and SCSI devices (with all their additional controller circuitry) function independently of one another, unlike IDE. Therefore, data can be read and written to any of the SCSI devices simultaneously. This enables smoother multitasking and increased overall data throughput. The most advanced operating systems, such as Windows NT/2000, even allow drive striping. A *striped drive set* is two or more drives that appear to the user as one drive. Data is split between the drives equally, again increasing overall throughput. Increased fault tolerance and performance are readily implemented and supported in SCSI drive arrays.

The new Ultra3 (Ultra160) SCSI drives offer even more advantages when compared with IDE. Ultra160 SCSI is 240% faster than UDMA/66 (Ultra DMA) IDE, which has a maximum data rate of 66MB/sec. Ultra160 SCSI also fully supports multitasking and can significantly improve system performance in workstations and servers running Windows NT or 2000. IDE limits cable lengths to 18 inches, effectively eliminating the ability to connect remote or external devices, whereas Ultra3 (Ultra160) SCSI allows external connections of up to 12 meters or more in length. Also note that IDE allows only 2 devices per cable, whereas Ultra160 SCSI can connect up to 15 devices. Finally, the domain validation feature of Ultra160 SCSI enables noise and other problems on the bus to be handled properly, whereas with IDE, if a problem occurs with the connection (and that is more common at the UDMA/66 speeds), the IDE drives simply fail.

IDE drives have much less command overhead for a given sector transfer than do SCSI drives. In addition to the drive-to-controller command overhead that both IDE and SCSI must perform, a SCSI transfer involves negotiating for the SCSI bus; selecting the target drive; requesting data; terminating the transfer over the bus; and finally converting the logical data addresses to the required cylinder, head, and sector addresses. This arrangement gives IDE an advantage in sequential transfers handled by a single-tasking operating system. In a multitasking system that can take advantage of the extra intelligence of the SCSI bus, SCSI can have the performance advantage.

SCSI drives offer significant architectural advantages over IDE and other drives. Because each SCSI drive has its own embedded disk controller that can function independently from the system CPU, the computer can issue simultaneous commands to every drive in the system. Each drive can store these commands in a queue and then perform the commands simultaneously with other drives in the system. The data could be fully buffered on the drive and transferred at high speed over the shared SCSI bus when a time slot was available.

Although IDE drives also have their own controllers, they do not operate simultaneously, and command queuing is not supported. In effect, the dual controllers in a dual-drive IDE installation work one at a time so as not to step on each other.

IDE does not support overlapped, multitasked I/O, which enables a device to take on multiple commands and work on them independently and in an order different from which they were received, releasing the bus for other devices to use. The ATA bus instead waits for each command to be completed before the next one can be sent.

As you can see, SCSI has some advantages over IDE, especially where expansion is concerned, and also with regard to support for multitasking operating systems. Unfortunately, it also costs more to implement.

One final advantage of SCSI is in the portability of external devices. It is easy to take an external SCSI CD-ROM, tape drive, scanner, or even a hard disk and quickly move it to another system. This allows moving peripherals more freely between systems and can be a bonus if you have several systems with which you might want to share a number of peripherals. Installing a new external SCSI device on a system is easier because you normally will not need to open it up.

Recommended SCSI Host Adapters

For SCSI host adapters, I normally recommend Adaptec. Its adapters work well and come with the necessary formatting and operating software. Windows 9x, Windows 2000, and even OS/2 have built-in support for Adaptec SCSI adapters. This support is a consideration in many cases because it frees you from having to deal with additional drivers.

Standard or Fast SCSI is adequately supported by the ISA bus, but if you are going to install a Wide SCSI bus—or especially an Ultra, Ultra2, or Ultra160 bus—you should consider some form of local bus SCSI adapter, normally PCI. This is because ISA supports a maximum transfer speed of only about 8MB/sec, whereas a Fast-Wide SCSI bus runs up to 20MB/sec, and an Ultra3 (Ultra160) SCSI bus runs up to a blazing 160MB/sec! In most cases, a local bus SCSI adapter would be a PCI bus version, which is supported in most current PC systems.

◀◀ See "The ISA Bus," p. 300.

◀◀ See "The PCI Bus," p. 310.

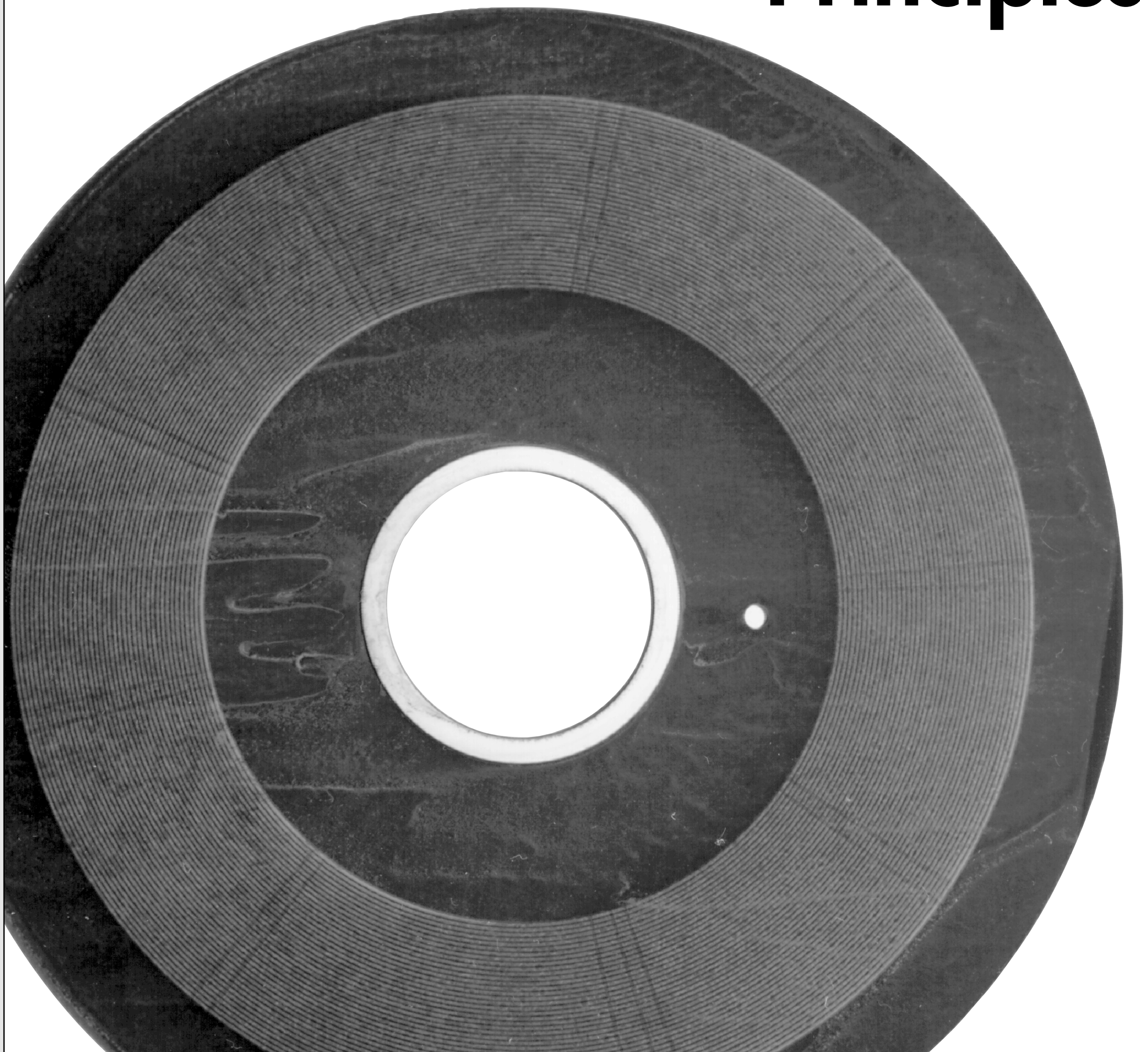
Like all modern PCI adapters, plug-and-play is supported, meaning virtually all functions on the card can be configured and set through software. No more digging through manuals or looking for interrupt, DMA, I/O port, and other jumper settings—everything is controlled by software and saved in a flash memory module on the card. Following are some features found on the latest SCSI cards:

- Complete configuration utility built into the adapter's ROM
- Software-configurable IRQ, ROM addresses, DMA, I/O port addresses, SCSI parity, SCSI ID, and other settings
- Software-selectable automatic termination (no resistors to pull out!)
- Enhanced BIOS support for up to 15 drives
- No drivers required for more than two hard disks
- Drive spin-up on a per-drive basis available
- Boots from any SCSI ID

Adaptec has full PnP support on all its SCSI adapters. These adapters either are automatically configured in any PC that supports the PnP specification or can be configured manually through supplied software in non-PnP systems. The PnP SCSI adapters are highly recommended because they can be configured without opening up the PC! All functions are set by software, and there are no jumpers or switches to attend to. Most peripheral manufacturers write drivers for Adaptec's cards first, so you will not have many compatibility or driver-support problems with any Adaptec card.

CHAPTER 9

Magnetic Storage Principles



Magnetic Storage

Permanent or semipermanent computer data storage works by either optical or magnetic principles or, in some cases, a combination of the two. In the case of magnetic storage, a stream of binary computer data bits (0s and 1s) is stored by magnetizing tiny pieces of metal embedded on the surface of a disk or tape in a pattern that represents the data. Later this magnetic pattern can be read and converted back into the exact same stream of bits you started with. This is the principle of magnetic storage and the subject of this chapter.

Magnetic storage is often difficult for people to understand because magnetic fields cannot be seen by the human eye. This chapter explains the principles, concepts, and techniques behind modern computer magnetic storage, enabling you to understand what is happening behind the scenes. This information is designed for those who have an insatiable curiosity about how these things work; it is not absolutely necessary to know this to use a PC or perform routine troubleshooting, maintenance, or upgrades. Because the data I store on my hard drives, tape drives, floppy drives, and other magnetic storage devices happens to be far more important to me than the devices themselves, knowing how my data is handled makes me feel much more comfortable with the system in general. Having an understanding of the underlying technology does help when it comes to dealing with problems that might arise.

This chapter covers magnetic storage principles and technology and can be considered an introduction to several other chapters in the book, including the following:

- Chapter 10, "Hard Disk Storage"
- Chapter 11, "Floppy Disk Storage"
- Chapter 12, "High-Capacity Removable Storage"
- Chapter 13, "Optical Storage"
- Chapter 14, "Physical Drive Installation and Configuration"

Consult these chapters for more specific information on various types of magnetic and optical storage, as well as drive installation and configuration.

History of Magnetic Storage

Before there was magnetic storage for computers, the primary storage medium was punched cards. What amazes me is that I missed contact with punched cards by about a year; the college I went to discontinued using them during my freshman year, before I was able to take any computer-related courses. I have to believe that this was more a reflection on their budget and lack of focus on current technology at the time (in 1979, there really weren't many punch-card readers being used in the field) than it is on my age!

The history of magnetic storage dates back to June 1949, when a group of IBM engineers and scientists began working on a new storage device. What they were working on was the first magnetic storage device for computers, and it revolutionized the industry. On May 21, 1952, IBM announced the IBM 726 Tape Unit with the IBM 701 Defense Calculator, marking the transition from punched-card calculators to electronic computers.

Four years later, on September 13, 1956, a small team of IBM engineers in San Jose, California, introduced the first computer disk storage system as part of the 305 RAMAC (Random Access Method of Accounting and Control) computer.

The 305 RAMAC drive could store five million characters (that's right, only 5MB!) of data on 50 disks, each a whopping 24 inches in diameter. Unlike tape drives, RAMAC's recording heads could go directly to any location on a disk surface without reading all the information in between. This random accessibility had a profound effect on computer performance at the time, enabling data to be stored and retrieved significantly faster than if it was on tape.

From these beginnings, the magnetic storage industry has progressed such that today you can store 75GB or more on tiny 3.5-inch drives that fit into a single computer drive bay.

IBM's contributions to the history and development of magnetic storage are incredible; in fact, most have either come directly from IBM or as a result of IBM research. Not only did IBM invent computer magnetic tape storage as well as the hard disk drive, but it also invented the floppy drive. The same San Jose facility where the hard drive was created introduced the first floppy drive, then using eight-inch diameter floppy disks, in 1971. The team that developed the drive was led by Alan Shugart, a now legendary figure in computer storage.

Since then, IBM has pioneered advanced magnetic data encoding schemes, such as Modified Frequency Modulation (MFM) and Run Length Limited (RLL); drive head designs, such as Thin Film, magneto-resistive (MR), and Giant magneto-resistive (GMR) heads; and drive technologies, such as Partial Response Maximum Likelihood (PRML), No-ID recording, and Self-Monitoring Analysis and Reporting Technology (S.M.A.R.T.). Today, IBM is arguably the leader in developing and implementing new drive technology and is second in sales only to Seagate Technology in PC hard drives.

How Magnetic Fields Are Used to Store Data

All magnetic storage devices, such as floppy disk drives and hard disk drives, read and write data by using electromagnetism. This basic principle of physics states that as an electric current flows through a conductor (wire), a magnetic field is generated around the conductor (see Figure 9.1). Note that electrons actually flow from negative to positive as shown in the figure, although we normally think of current flowing in the other direction.

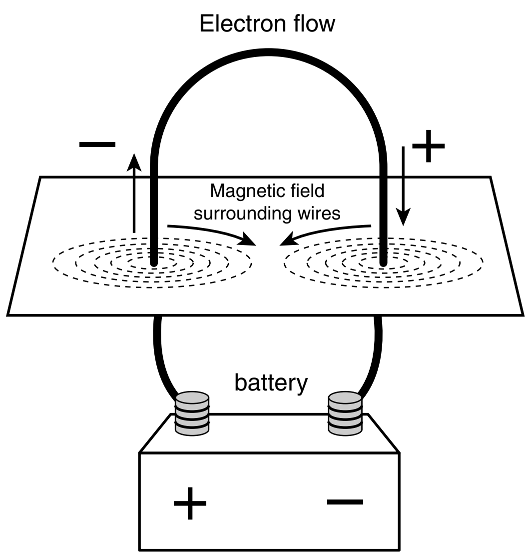


Figure 9.1 A magnetic field is generated around a wire when current is passed through it.

Electromagnetism was discovered in 1819 by Danish physicist Hans Christian Oersted, when he found that a compass needle would deflect away from pointing north when brought near a wire conducting an electric current. When the current was shut off, the compass needle resumed its alignment with the Earth's magnetic field and again pointed north.

The magnetic field generated by a wire conductor can exert an influence on magnetic material in the field. When the direction of the flow of electric current or polarity is reversed, the magnetic field's polarity also is reversed. For example, an electric motor uses electromagnetism to exert pushing and pulling forces on magnets attached to a rotating shaft.

Another effect of electromagnetism was discovered by Michael Faraday in 1831. He found that if a conductor is passed through a moving magnetic field, an electrical current is generated. As the polarity of the magnetic field changes, so does the direction of the electric current's flow (see Figure 9.2).

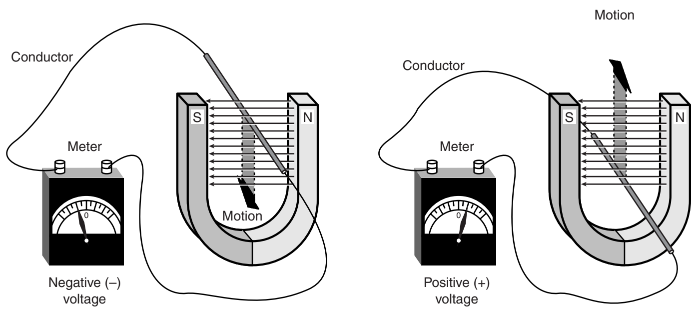

Figure 9.2 Current is induced in a wire when passed through a magnetic field.

For example, an alternator, which is a type of electrical generator used in automobiles, operates by rotating electromagnets on a shaft past coils of stationary wire conductors, which consequently generates large amounts of electrical current in those conductors. Because electromagnetism works two ways, a motor can become a generator and vice versa. When applied to magnetic storage devices, this two-way operation of electromagnetism makes recording data on a disk and reading that data back later possible. When recording, the head changes electrical impulses to magnetic fields, and when reading, the head changes magnetic fields back into electrical impulses.

The read/write heads in a magnetic storage device are U-shaped pieces of conductive material, with the ends of the U situated directly above (or next to) the surface of the actual data storage medium. The U-shaped head is wrapped with coils or windings of conductive wire, through which an electric current can flow (see Figure 9.3). When the drive logic passes a current through these coils, it generates a magnetic field in the drive head. Reversing the polarity of the electric current causes the polarity of the generated field to change also. In essence, the heads are electromagnets whose voltage can be switched in polarity very quickly.

The disk or tape that constitutes the actual storage medium consists of some form of substrate material (such as Mylar for floppy disks or aluminum or glass for hard disks) on which a layer of magnetizable material has been deposited. This material usually is a form of iron oxide with various other elements added. Each of the individual magnetic particles on the storage medium has its own magnetic field. When the medium is blank, the polarities of those magnetic fields are normally in a state of random disarray. Because the fields of the individual particles point in random directions, each tiny magnetic field is canceled out by one that points in the opposite direction; the cumulative effect of this is a surface with no observable field polarity. With many randomly oriented fields, the net effect is no observable unified field or polarity.

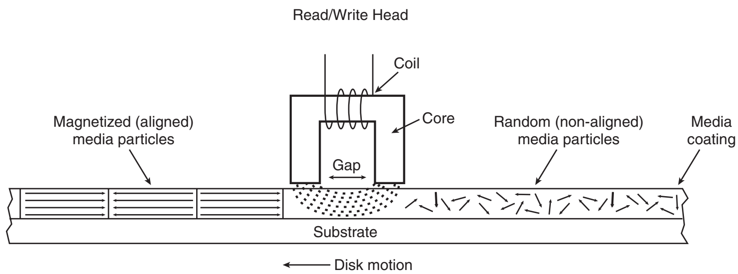

Figure 9.3 A magnetic read/write head.

When a drive's read/write head generates a magnetic field, the field jumps the gap between the ends of the U shape. Because a magnetic field passes through a conductor much more easily than through the air, the field bends outward from the gap in the head and actually uses the adjacent storage medium as the path of least resistance to the other side of the gap. As the field passes through the medium directly under the gap, it polarizes the magnetic particles it passes through so they are aligned with the field. The field's polarity or direction—and, therefore, the polarity or direction of the field induced in the magnetic medium—is based on the direction of the flow of electric current through the coils. A change in the direction of the current flow produces a change in the direction of the magnetic field. During the development of magnetic storage, the distance between the read/write head and the media has decreased dramatically. This enables the gap to be smaller and also makes the size of the recorded magnetic domain smaller. The smaller the recorded magnetic domain, the higher the density of data that can be stored on the drive.

When the magnetic field passes through the medium, the particles in the area below the head gap are aligned in the same direction as the field emanating from the gap. When the individual magnetic domains of the particles are in alignment, they no longer cancel one another out, and an observable magnetic field exists in that region of the medium. This local field is generated by the many magnetic particles that now are operating as a team to produce a detectable cumulative field with a unified direction.

The term *flux* describes a magnetic field that has a specific direction or polarity. As the surface of the medium moves under the drive head, the head can generate what is called a *magnetic flux* of a given polarity over a specific region of the medium. When the flow of electric current through the coils in the head is reversed, so is the magnetic field polarity or flux in the head gap. This flux reversal in the head causes the polarity of the magnetized particles on the disk medium to reverse.

The flux reversal or flux transition is a change in the polarity of the aligned magnetic particles on the surface of the storage medium. A drive head creates flux reversals on the medium to record data. For each data bit (or bits) that a drive writes, it creates a pattern of positive-to-negative and negative-to-positive flux reversals on the medium in specific areas known as *bit cells* or *transition cells*. A bit cell or transition cell is a specific area of the medium—controlled by the time and speed at which the medium travels—in which the drive head creates flux reversals. The particular pattern of flux reversals within the transition cells used to store a given data bit (or bits) is called the *encoding method*. The drive logic or controller takes the data to be stored and encodes it as a series of flux reversals over a period of time, according to the pattern dictated by the encoding method it uses.

Note

The two most popular encoding methods for magnetic media are Modified Frequency Modulation (MFM) and Run Length Limited (RLL). All floppy disk drives and some older hard disk drives use the MFM scheme. Today's hard disk drives use one of several variations on the RLL encoding method. These encoding methods are described in more detail later in this chapter in the section "Data Encoding Schemes."

During the write process, voltage is applied to the head. As the polarity of this voltage changes, the polarity of the magnetic field being recorded also changes. The flux transitions are written precisely at the points where the recording polarity changes. Strange as it might seem, during the read process, a head does not generate exactly the same signal that was written. Instead, the head generates a voltage pulse or spike only when it crosses a flux transition. When the transition changes from positive to negative, the pulse that the head detects is a negative voltage. When the transition changes from negative to positive, the pulse is a positive voltage spike. This effect occurs because current is generated in a conductor only when passing through lines of magnetic force at an angle. Because the head moves parallel to the magnetic fields it created on the media, the only time the head generates voltage when reading is when passing through a polarity or flux transition (flux reversal).

In essence, while reading from the medium, the head becomes a flux transition detector, emitting voltage pulses whenever it crosses a transition. Areas of no transition generate no pulse. Figure 9.4 shows the relationship between the read and write waveforms and the flux transitions recorded on a storage medium.

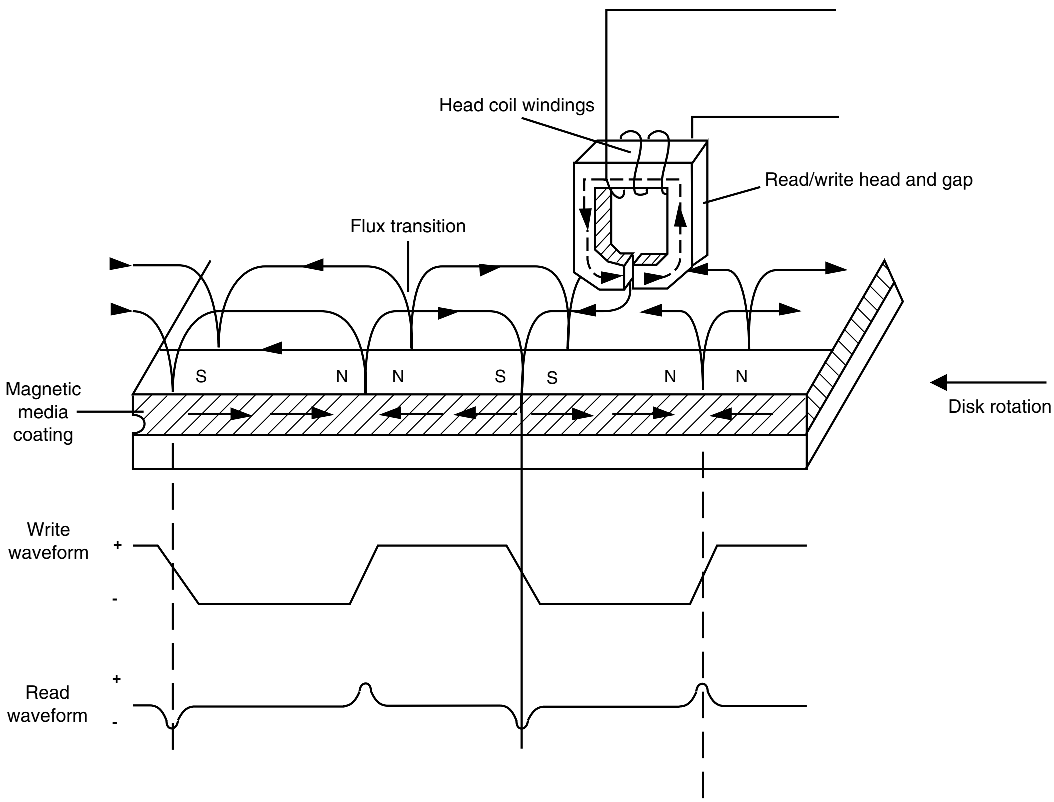

Figure 9.4 Magnetic write and read processes.

You can think of the write pattern as being a square waveform that is at a positive or negative voltage level. When the voltage is positive, a field is generated in the head, which polarizes the magnetic media in one direction. When the voltage changes to negative, the magnetic field induced in the media also changes direction. Where the waveform actually transitions from positive to negative voltage, or vice versa, the magnetic flux on the disk also changes polarity. During a read, the head senses these flux transitions and generates a pulsed positive or negative waveform, rather than the continuously positive or negative waveform used during the original recording. In other words, the signal when reading is 0 volts unless the head detects a magnetic flux transition, in which case it generates a positive or negative pulse accordingly. Pulses appear only when the head is passing over flux transitions on the medium. By knowing the clock timing the drive uses, the controller circuitry can determine whether a pulse (and therefore a flux transition) falls within a given transition cell time period.

The electrical pulse currents generated in the head while it is passing over the storage medium in read mode are very weak and can contain significant noise. Sensitive electronics in the drive and controller assembly amplify the signal above the noise level and decode the train of weak pulse currents back into binary data that is (theoretically) identical to the data originally recorded.

As you can see, hard disk drives and other storage devices read and write data by means of basic electromagnetic principles. A drive writes data by passing electrical currents through an electromagnet (the drive head), generating a magnetic field that is stored on the medium. The drive reads data by passing the head back over the surface of the medium. As the head encounters changes in the stored magnetic field, it generates a weak electrical current that indicates the presence or absence of flux transitions in the signal as it was originally written.

Read/Write Head Designs

As disk drive technology has evolved, so has the design of the read/write head. The earliest heads were simple iron cores with coil windings (electromagnets). By today's standards, the original head designs were enormous in physical size and operated at very low recording densities. Over the years, head designs have evolved from the first simple ferrite core designs into the several types and technologies available today. This section discusses the various types of heads found in PC hard disk drives, including the applications and relative strengths and weaknesses of each.

Five main types of heads have been used in hard disk drives over the years:

- Ferrite
- Thin-Film (TF)
- Metal-In-Gap (MIG)
- Magneto-resistive (MR)
- Giant Magneto-resistive (GMR)

Ferrite

Ferrite heads, the traditional type of magnetic-head design, evolved from the original IBM 30-30 Winchester drive. These heads have an iron-oxide core wrapped with electromagnetic coils. The drive produces a magnetic field by energizing the coils or by passing a magnetic field near them. This gives the heads full read/write capability. Ferrite heads are larger and heavier than thin-film heads and therefore require a larger floating height to prevent contact with the disk while it is spinning.

Manufacturers have made many refinements to the original (monolithic) ferrite head design. One type of ferrite head, called a composite ferrite head, has a smaller ferrite core bonded with glass in a ceramic housing. This design permits a smaller head gap, which enables higher track densities. These heads are less susceptible to stray magnetic fields than the older monolithic design heads.

During the 1980s, composite ferrite heads were popular in many low-end drives, such as the Seagate ST-225. As density demands grew, the competing MIG and thin-film head designs came to be used in place of ferrite heads, which are virtually obsolete today. Ferrite heads cannot write to the higher coercivity media necessary for high-density disk designs and have poor frequency response with higher noise levels. The main advantage of ferrite heads is that they are the cheapest type available.

Metal-In-Gap

Metal-In-Gap heads are a specially enhanced version of the composite ferrite design. In MIG heads, a metal substance is applied to the head's recording gap. Two versions of MIG heads are available: single-sided and double-sided. Single-sided MIG heads are designed with a layer of magnetic alloy placed along the trailing edge of the gap. Double-sided MIG designs apply the layer to both sides of the gap. The metal alloy is applied through a vacuum-deposition process called sputtering.

This magnetic alloy has twice the magnetization capability of raw ferrite and enables the head to write to the higher coercivity thin-film media needed at the higher densities. MIG heads also produce a sharper gradient in the magnetic field for a better-defined magnetic pulse. Double-sided MIG heads offer even higher coercivity capability than the single-sided designs.

Because of these increases in capabilities through improved designs, MIG heads were for a time the most popular head design and were used in many hard disk drives in the late '80s and early '90s. They are still used today in LS-120 (SuperDisk) drives.

Thin Film

Thin-film heads are manufactured much the same way as a semiconductor chip—through a photolithographic process. This process creates many thousands of heads on a single circular wafer and produces a very small, high-quality product.

TF heads have an extremely narrow and controlled head gap that is created by sputtering a hard aluminum material. Because this material completely encloses the gap, the area is very well protected, minimizing the chance of damage from contact with the spinning disk. The core is a combination of iron and nickel alloy that has two to four times more magnetic power than a ferrite head core.

TF heads produce a sharply defined magnetic pulse that enables them to write at extremely high densities. Because they do not have a conventional coil, TF heads are more immune to variations in coil impedance. These small, lightweight heads can float at a much lower height than the ferrite and MIG heads; in some designs, the floating height is two micro-inches or less. Because the reduced height enables the heads to pick up and transmit a much stronger signal from the platters, the signal-to-noise ratio increases, improving accuracy. At the high track and linear densities of some drives, a standard ferrite head would not be capable of picking out the data signal from the background noise. Another advantage of TF heads is that their small size enables the platters to be stacked closer together, enabling more platters to fit into the same space.

Until the past few years, TF heads were relatively expensive compared with older technologies, such as ferrite and MIG. Better manufacturing techniques and the need for higher densities, however, have driven the market to TF heads. The widespread use of these heads has also made them cost-competitive with, if not cheaper than, MIG heads.

Many of the drives in the 100MB to 2GB range used TF heads, especially in the smaller form factors. TF heads displaced MIG heads as the most popular head design, but they have now themselves been displaced by newer magneto-resistive heads.

Magneto-Resistive Heads

A more recent development in magnetic recording, or more specifically, the read phase of magnetic recording, is the magneto-resistive head, sometimes also referred to as the anisotropic magneto-resistant (AMR) head. In the last few years, virtually all modern hard disk designs have shifted to using MR heads. MR heads are capable of increasing density four times or greater as compared to the previous inductive-only heads. IBM introduced the first commercially available drive with MR heads in 1991, in a 1GB 3.5-inch model.

All heads are detectors; that is, they are designed to detect the flux transitions in the media and convert them back to an electrical signal that can be interpreted as data. One problem with magnetic recording is the ever increasing desire for more and more density, which is putting more information (flux transitions) in a smaller and smaller space. As the magnetic domains on the disk get smaller, the signal from the heads during reading operations becomes weaker; distinguishing the true signal from the random noise or stray fields present becomes difficult. What is needed is a more efficient read head, which is a more efficient way to detect these transitions on the disk.

Another magnetic effect that is well known today is being used in modern drives. When a wire is passed through a magnetic field, not only does the wire generate a small current, but the resistance of the wire also changes. Standard read heads use the head as a tiny generator, relying on the fact that the heads will generate a pulsed current when passed over magnetic flux transitions. A newer type of head design pioneered by IBM instead relies on the fact that the resistance in the head wires will also change.

Rather than use the head to generate tiny currents, which must then be filtered, amplified, and decoded, a magneto-resistive head uses the head as a resistor. A circuit passes a voltage through the head and watches for the voltage to change, which will occur when the resistance of the head changes as it passes through the flux reversals on the media. This mechanism for using the head results in a much stronger and clearer signal of what was on the media and enables the density to be increased.

MR heads rely on the fact that the resistance of a conductor changes slightly when an external magnetic field is present. Rather than put out a voltage by passing through a magnetic-field flux reversal—as a normal head would—the MR head senses the flux reversal and changes resistance. A small current flows through the heads, and this sense current measures the change in resistance. This design provides an output that is three or more times more powerful than a TF head during a read. In effect, MR heads are power-read heads, acting more like sensors than generators.

MR heads are more costly and complex to manufacture than other types of heads because several special features or steps must be added:

- Additional wires must be run to and from the head to carry the sense current.
- Four to six more masking steps are required.
- Because MR heads are so sensitive, they are very susceptible to stray magnetic fields and must be shielded.

Because the MR principle can only read data and is not used for writing, MR heads are really two heads in one. The assembly includes a standard inductive TF head for writing data and an MR head for reading. Because two separate heads are built into one assembly, each head can be optimized for its task. Ferrite, MIG, and TF heads are known as single-gap heads because the same gap is used for both reading and writing, whereas the MR head uses a separate gap for each operation.

The problem with single-gap heads is that the gap length is always a compromise between what is best for reading and what is best for writing. The read function needs a thin gap for higher resolution; the write function needs a thicker gap for deeper flux penetration to switch the medium. In a dual-gap MR head, the read and write gaps can be optimized for both functions independently. The write (TF) gap writes a wider track than the read (MR) gap reads. Thus, the read head is less likely to pick up stray magnetic information from adjacent tracks.

A typical IBM-designed MR head is shown in Figure 9.5. This figure first shows the complete MR head-and-slider assembly on the end of an actuator arm. This is the part you would see if you opened up a drive. The slider is the block device on the end of the triangular-shaped arm that carries the head. The actual head is the tiny piece shown magnified at the end of the slider, and then the MR read sensor in the head is shown further magnified.

The read element, which is the actual magneto-resistive sensor, consists of a nickel-ferrite (NiFe) film separated by a spacer from a magnetically soft layer. The NiFe film layer changes resistance in the presence of a magnetic field. Layers of shielding protect the MR sensor read element from being corrupted by adjacent or stray magnetic fields. In many designs, the second shield also functions as one pole of the write element, resulting in what is called a *merged* MR head. The write element is not of MR design but is instead a traditional thin film inductive head.

IBM's MR head design employs a Soft Adjacent Layer (SAL) structure, consisting of the MR NiFe film, as well as a magnetically soft alloy layer separated by a film with high electrical resistance. In this design a resistance change occurs in the NiFe layer as the MR sensor passes through a magnetic field.

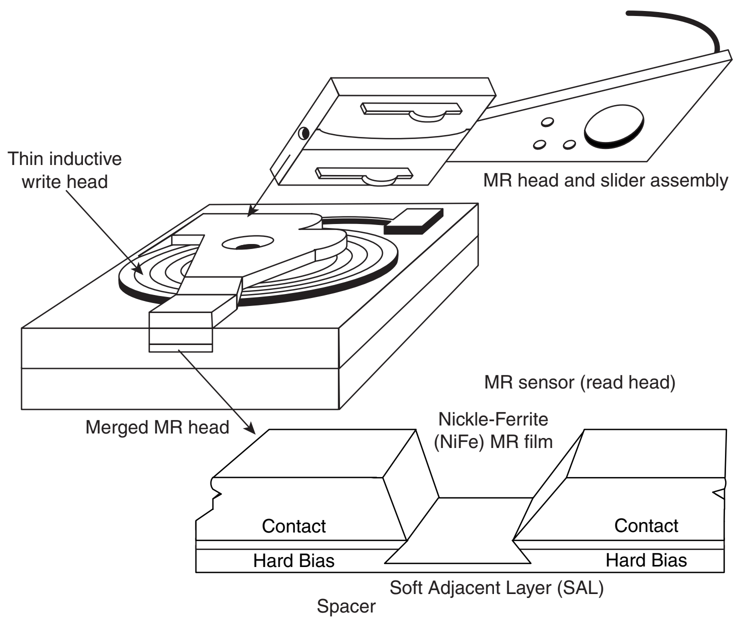

Figure 9.5 Cross section of a magneto-resistive head.

As areal densities have increased, heads have been designed with narrower and thinner MR elements. The newest heads have reduced the film width between the side contacts to as little as half a micron or less.

Giant Magneto-Resistive Heads

In the quest for even more density, IBM introduced a new type of MR head in 1997. Called giant magneto-resistive (GMR) heads, they are physically smaller than standard MR heads but are so named for the GMR effect on which they are based. The design is very similar; however, additional layers replace the single NiFe layer in a conventional MR design. In MR heads, a single NiFe film changes resistance in response to a flux reversal on the disk. In GMR heads, two films (separated by a very thin copper conducting layer) perform this function.

The GMR effect was first discovered in 1988 in crystal samples exposed to high-powered magnetic fields (1,000 times the fields used in HDDs). It was discovered that large resistance changes were occurring in materials comprised of alternating very thin layers of various metallic elements. The key structure in GMR materials is a spacer layer of a nonmagnetic metal between two layers of magnetic metals. One of the magnetic layers is *pinned*, which means it has a forced magnetic orientation. The other magnetic layer is *free*, which means it is free to change orientation or alignment. Magnetic materials tend to align themselves in the same direction. So if the spacer layer is thin enough, the free layer takes on the same orientation as the pinned layer. What was discovered was that the magnetic alignment of the free magnetic layer would periodically swing back and forth from being aligned in the same magnetic direction as the pinned layer to being aligned in opposite magnetic directions. The overall resistance is relatively low when the layers were in the same alignment and relatively high when in opposite magnetic alignment.

Figure 9.6 shows a GMR read element.

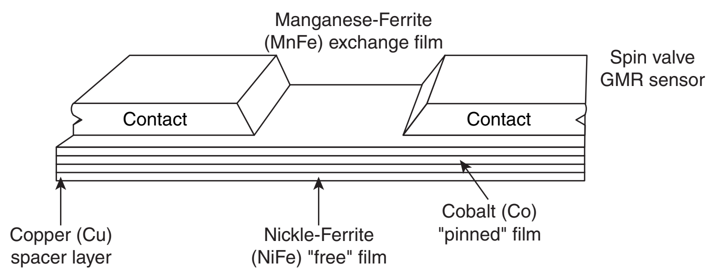

Figure 9.6 Cross section of a giant magneto-resistive head.

When a weak magnetic field, such as that from a bit on a hard disk, passes beneath a GMR head, the magnetic orientation of the free magnetic layer rotates relative to that of the other, generating a significant change in electrical resistance due to the GMR effect. Because the physical nature of the resistance change was determined to be caused by the relative spin of the electrons in the different layers, GMR heads are often referred to as *spin-valve heads*.

IBM announced the first commercially available drive using GMR heads (a 16.8GB 3.5-inch drive) in December 1997. Since then, GMR heads have become the standard in most drives of 20GB and beyond. The latest GMR drives have data densities exceeding 20GB per platter, enabling drives as large as 80GB to be produced in the standard 3.5-inch wide, 1-inch high form factor.

Head Sliders

The term *slider* is used to describe the body of material that supports the actual drive head itself. The slider is what actually floats or slides over the surface of the disk, carrying the head at the correct distance from the medium for reading and writing. Most sliders resemble a trimaran, with two outboard pods that float along the surface of the disk media and a central "hull" portion that actually carries the head and the read/write gap. Figure 9.7 shows a typical slider. Note the actual head, with the read/write gap, is on the trailing end of the slider.

The trend toward smaller and smaller form factor drives has forced sliders to become smaller and smaller as well. The typical mini-Winchester slider design is about .160×.126×.034 inches in size. Most head manufacturers have now shifted to 50% smaller nanosliders, or 70% smaller picosliders. A nanoslider has dimensions of about .08×.063×.017 inches, whereas the smaller picoslider is .049×.039×.012 inches. Picosliders are assembled by using flex interconnect cable (FIC) and chip on ceramic (COC) technology that enables the process to be completely automated.

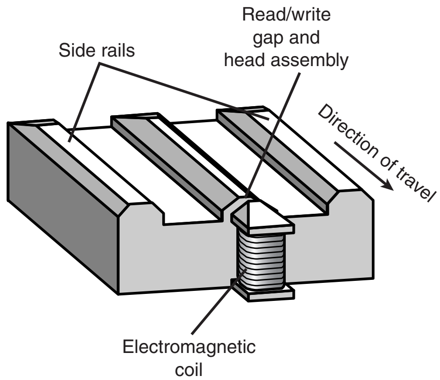

Figure 9.7 The underside of a typical head slider.

Smaller sliders reduce the mass carried at the end of the head actuator arms, providing increased acceleration and deceleration, leading to faster seek times. The smaller sliders also require less area for a landing zone, thus increasing the usable area of the disk platters. Further, the smaller slider contact area reduces the slight wear on the platter surface that occurs during normal startup and spindown of the drive platters.

The newer nanoslider and picoslider designs also have specially modified surface patterns that are designed to maintain the same floating height above the disk surface, whether the slider is positioned above the inner or outer cylinders. Conventional sliders increase or decrease their floating heights considerably, according to the velocity of the disk surface traveling beneath them. Above the outer cylinders, the velocity and floating height are higher. This arrangement is undesirable in newer drives that use zoned bit recording, in which the bit density is the same on all the cylinders. When the bit density is uniform throughout the drive, the head floating height should be relatively constant as well for maximum performance. Special textured surface patterns and manufacturing techniques enable the sliders to float at a much more consistent height, making them ideal for zoned bit recording drives. For more information on zoned recording, see the section "Disk Formatting" in Chapter 10.

Data Encoding Schemes

Magnetic storage is essentially an analog medium. The data a PC stores on it, however, is digital information—that is, 1s and 0s. When the drive sends digital information to a magnetic recording head, the head creates magnetic domains on the storage medium with specific polarities corresponding to the positive and negative voltages the drive applies to the head. It is the flux reversals that form the boundaries between the areas of positive and negative polarity that the drive controller uses to encode the digital data onto the analog medium. During a read operation, each flux reversal the drive detects generates a positive or negative pulse that the device uses to reconstruct the original binary data.

To optimize the placement of flux transitions during magnetic storage, the drive passes the raw digital input data through a device called an encoder/decoder (endec), which converts the raw binary information to a waveform designed to optimally place the flux transitions (pulses) on the media. During a read operation, the endec reverses the process and decodes the pulse train back into the original binary data. Over the years, several schemes for encoding data in this manner have been developed; some are better or more efficient than others, which you see later in this section.

Other descriptions of the data encoding process might be much simpler, but they omit the facts that make some of the issues related to hard drive reliability so critical—namely, timing. Engineers and designers are constantly pushing the envelope to stuff more and more bits of information into the limited quantity of magnetic flux reversals per inch. What they've came up with, essentially, is a design in which the bits of information are not only decoded from the presence or absence of flux reversals, but from the timing between them. The more accurately they can time the reversals, the more information that can be encoded (and subsequently decoded) from that timing information.

In any form of binary signaling, the use of timing is significant. When interpreting a read or write waveform, the timing of each voltage transition event is critical. Timing is what defines a particular bit or transition cell—that is, the time window within which the drive is either writing or reading a transition. If the timing is off, a given voltage transition might be recognized at the wrong time as being in a different cell, which would throw the conversion or encoding off, resulting in bits being missed, added, or misinterpreted. To ensure that the timing is precise, the transmitting and receiving devices must be in perfect synchronization. For example, if recording a zero is done by placing no transition on the disk for a given time period or cell, imagine recording 10 zero bits in a row—you would have a long period of 10 time periods or cells with no transitions.

Imagine now that the clock on the encoder was slightly off time while reading data as compared to when it was originally written. If it were fast, the encoder might think that during this long stretch of 10 cells with no transitions, only nine cells had actually elapsed. Or if it were slow, it might think that 11 cells had elapsed instead. In either case, this would result in a read error, meaning the bits that were originally written would not be read as being the same. To prevent timing errors in drive encoding/decoding, perfect synchronization is necessary between the reading and writing processes. This synchronization often is accomplished by adding a separate timing signal, called a *clock signal*, to the transmission between the two devices. The clock and data signals also can be combined and transmitted as a single signal. Most magnetic data encoding schemes use this type of combination of clock and data signals.

Adding a clock signal to the data ensures that the communicating devices can accurately interpret the individual bit cells. Each bit cell is bounded by two other cells containing the clock transitions. By sending clock information along with the data, the clocks remain in sync, even if the medium contains a long string of identical zero bits. Unfortunately, the transition cells used solely for timing take up space on the medium that could otherwise be used for data.

Because the number of flux transitions a drive can record in a given space on a particular medium is limited by the physical nature or density of the medium and the head technology, drive engineers have developed various ways of encoding the data by using a minimum number of flux reversals (taking into consideration the fact that some flux reversals used solely for clocking are required). Signal encoding enables the system to make the maximum use of a given drive hardware technology.

Although various encoding schemes have been tried, only a few are popular today. Over the years, these three basic types have been the most popular:

- Frequency Modulation
- Modified Frequency Modulation
- Run Length Limited

The following sections examine these codes, how they work, where they are used, and any advantages or disadvantages that apply to them. It will help to refer to Figure 9.8 (later in the chapter) as you read the descriptions of each of these encoding schemes because this figure depicts how each of these schemes would store an "X" on the same media.

FM Encoding

One of the earliest techniques for encoding data for magnetic storage is called Frequency Modulation encoding. This encoding scheme—sometimes called Single-Density encoding—was used in the earliest floppy disk drives installed in PC systems. The original Osborne portable computer, for example, used these Single-Density floppy disk drives, which stored about 80KB of data on a single disk. Although it was popular until the late 1970s, FM encoding is no longer used.

MFM Encoding

Modified Frequency Modulation encoding was devised to reduce the number of flux reversals used in the original FM encoding scheme and, therefore, to pack more data onto the disk. MFM encoding minimizes the use of clock transitions, leaving more room for the data. MFM records clock transitions only when a stored zero bit is preceded by another zero bit; in all other cases, a clock transition is not required. Because MFM minimizes the use of clock transitions, it can double the clock frequency used by FM encoding, enabling it to store twice as many data bits in the same number of flux transitions.

Because MFM encoding writes twice as many data bits by using the same number of flux reversals as FM, the clock speed of the data is doubled, so the drive actually sees the same number of total flux reversals as with FM. This means a drive using MFM encoding reads and writes data at twice the speed of FM, even though the drive sees the flux reversals arriving at the same frequency as in FM.

Because it is twice as efficient as FM encoding, MFM encoding also has been called Double-Density recording. MFM is used in virtually all PC floppy disk drives today and was used in nearly all PC hard disks for a number of years. Today, virtually all hard disks use variations of RLL encoding, which provides even greater efficiency than MFM.

Table 9.1 shows the data bit to flux reversal translation in MFM encoding.

Table 9.1 MFM Data to Flux Transition Encoding

Data Bit Value	Flux Encoding
1	NT
0 preceded by 0	TN
0 preceded by 1	NN

T = Flux transition

N = No flux transition

RLL Encoding

Today's most popular encoding scheme for hard disks, called Run Length Limited, packs up to twice the information on a given disk than MFM does and three times as much information as FM. In RLL encoding, the drive combines groups of bits into a unit to generate specific patterns of flux reversals. By combining the clock and data signals in these patterns, the clock rate can be further increased while maintaining the same basic distance between the flux transitions on the storage medium.

IBM invented RLL encoding and first used the method in many of its mainframe disk drives. During the late 1980s, the PC hard disk industry began using RLL encoding schemes to increase the storage capabilities of PC hard disks. Today, virtually every drive on the market uses some form of RLL encoding.

Instead of encoding a single bit, RLL normally encodes a group of data bits at a time. The term *Run Length Limited* is derived from the two primary specifications of these codes, which are the minimum number (the run length) and maximum number (the run limit) of transition cells allowed between two actual flux transitions. Several variations of the scheme are achieved by changing the length and limit parameters, but only two have achieved any real popularity: RLL 2,7 and RLL 1,7.

You can even express FM and MFM encoding as a form of RLL. FM can be called RLL 0,1, because as few as zero and as many as one transition cells separate two flux transitions. MFM can be called RLL 1,3, because as few as one and as many as three transition cells separate two flux transitions. (Although these codes can be expressed as variations of RLL form, it is not common to do so.)

RLL 2,7 was initially the most popular RLL variation because it offers a high-density ratio with a transition detection window that is the same relative size as that in MFM. This method provides high storage density and fairly good reliability. In very high-capacity drives, however, RLL 2,7 did not prove to be reliable enough. Most of today's highest capacity drives use RLL 1,7 encoding, which offers a density ratio 1.27 times that of MFM and a larger transition detection window relative to MFM. Because of the larger relative timing window or cell size within which a transition can be detected, RLL 1,7 is a more forgiving and more reliable code, which is important when media and head technology are being pushed to their limits.

Another little-used RLL variation called RLL 3,9—sometimes called Advanced RLL (ARLL)—allows an even higher density ratio than RLL 2,7. Unfortunately, reliability suffered too greatly under the RLL 3,9 scheme; the method was used by only a few now-obsolete controllers and has all but disappeared.

Understanding how RLL codes work is difficult without looking at an example. Within a given RLL variation such as RLL 2,7 or 1,7, you can construct many flux transition encoding tables to demonstrate how particular groups of bits are encoded into flux transitions.

In the conversion table shown in Table 9.2, specific groups of data bits two, three, and four bits long are translated into strings of flux transitions 4, 6, and 8 transition cells long, respectively. The selected transitions for a particular bit sequence are designed to ensure that flux transitions do not occur too close together or too far apart.

Limiting how close two flux transitions can be is necessary because of the fixed resolution capabilities of the head and the storage medium. Limiting how far apart two flux transitions can be ensures that the clocks in the devices remain in sync.

Table 9.2 RLL 2,7 Data to Flux Transition Encoding

Data Bit Values	Flux Encoding
10	NTNN
11	TNNN
000	NNNTNN
010	TNNTNN
011	NNTNNN
0010	NNTNNTNN
0011	NNNNTNNN

T = Flux transition

N = No flux transition

In studying this table, you might think that encoding a byte value such as 00000001b would be impossible because no combinations of data bit groups fit this byte. Encoding this type of byte is not a problem, however, because the controller does not transmit individual bytes; instead, the controller sends whole sectors, making encoding such a byte possible by including some of the bits in the following byte. The only real problem occurs in the last byte of a sector, if additional bits are necessary to complete the final group sequence. In these cases, the endec in the controller adds excess bits to the end of the last byte. These excess bits are truncated during any reads so the controller always decodes the last byte correctly.

Encoding Scheme Comparisons

Figure 9.8 shows an example of the waveform written to store the ASCII character X on a hard disk drive by using three different encoding schemes.

In each of these encoding scheme examples, the top line shows the individual data bits (01011000b, for example) in their bit cells separated in time by the clock signal, which is shown as a period (.). Below that line is the actual write waveform, showing the positive and negative voltages as well as head voltage transitions that result in the recording of flux transitions. The bottom line shows the transition cells, with T representing a transition cell that contains a flux transition and N representing a transition cell that is empty.

The FM encoding example shown in Figure 9.8 is easy to explain. Each bit cell has two transition cells: one for the clock information and one for the data itself. All the clock transition cells contain flux transitions, and the data transition cells contain a flux transition only if the data is a one bit. No transition is present when the data is a zero bit. Starting from the left, the first data bit is 0, which decodes as a flux transition pattern of TN. The next bit is a 1, which decodes as TT. The next bit is 0, which decodes as TN, and so on.

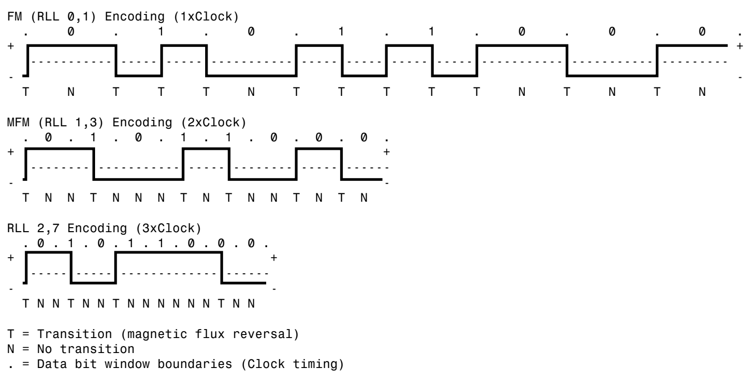

Figure 9.8 ASCII character "X" write waveforms using FM, MFM, and RLL 2,7 encoding.

The MFM encoding scheme also has clock and data transition cells for each data bit to be recorded. As you can see, however, the clock transition cells carry a flux transition only when a zero bit is stored after another zero bit. Starting from the left, the first bit is a 0, and the preceding bit is unknown (assume 0), so the flux transition pattern is TN for that bit. The next bit is a 1, which always decodes to a transition-cell pattern of NT. The next bit is 0, which was preceded by 1, so the pattern stored is NN. By using Table 9.1 (shown earlier), you easily can trace the MFM encoding pattern to the end of the byte. You can see that the minimum and maximum number of transition cells between any two flux transitions are one and three, respectively, which explains why MFM encoding can also be called RLL 1,3.

The RLL 2,7 pattern is more difficult to see because it encodes groups of bits rather than individual bits. Starting from the left, the first group that matches the groups listed in Table 9.2 is the first three bits, 010. These bits are translated into a flux transition pattern of TNNTNN. The next two bits, 11, are translated as a group to TNNN; and the final group, 000 bits, is translated to NNNTNN to complete the byte. As you can see in this example, no additional bits were needed to finish the last group.

Notice that the minimum and maximum number of empty transition cells between any two flux transitions in this example are 2 and 6, although a different example could show a maximum of seven empty transition cells. This is where the RLL 2,7 designation comes from. Because even fewer transitions are recorded than in MFM, the clock rate can be increased to three times that of FM or 1.5 times that of MFM, thus storing more data in the same space. Notice, however, that the resulting write waveform itself looks exactly like a typical FM or MFM waveform in terms of the number and separation of the flux transitions for a given physical portion of the disk. In other words, the physical minimum and maximum distances between any two flux transitions remain the same in all three of these encoding scheme examples.

Partial-Response, Maximum-Likelihood Decoders

Another feature often used in modern hard disk drives involves the disk read circuitry. Read channel circuits using Partial-Response, Maximum-Likelihood (PRML) technology enable disk drive manufacturers to increase the amount of data stored on a disk platter by up to 40%. PRML replaces the standard "detect one peak at a time" approach of traditional analog peak-detect, read/write channels with digital signal processing.

As the data density of hard drives increases, the drive must necessarily record the flux reversals closer together on the medium. This makes reading the data on the disk more difficult because the adjacent magnetic peaks can begin to interfere with each other. PRML modifies the way the drive reads the data from the disk. The controller analyzes the analog data stream it receives from the heads by using digital signal sampling, processing, and detection algorithms (this is the partial response element) and predicts the sequence of bits the data stream is most likely to represent (the maximum likelihood element). PRML technology can take an analog waveform, which might be filled with noise and stray signals, and produce an accurate reading from it.

This might not sound like a very precise method of reading data that must be bit-perfect to be usable, but the aggregate effect of the digital signal processing filters out the noise efficiently enough to enable the drive to place the flux change pulses much closer together on the platter, thus achieving greater densities. Most drives with capacities of 2GB or above use PRML technology in their endec circuits.

Capacity Measurements

In December 1998, the International Electrotechnical Commission (IEC)—the leading international organization for worldwide standardization in electrotechnology—approved as an IEC International Standard names and symbols for prefixes for binary multiples for use in the fields of data processing and data transmission. Prior to this there had been a lot of confusion as to whether a megabyte stood for 1 million bytes (10^6) or 1,048,576 bytes (2^{20}). Even so, these new prefixes have yet to be widely adopted and confusion still reigns. The industry-standard abbreviations for the units used to measure the capacity of magnetic (and other) drives are shown in Table 9.3.

Table 9.3 Standard Abbreviations and Meanings

Abbreviation	Description	Power	Value
K	Kilo	10^3	1,000
Ki	Kibi	2^{10}	1,024
M	Mega	10^6	1,000,000
Mi	Mebi	2^{20}	1,048,576
G	Giga	10^9	1,000,000,000
Gi	Gibi	2^{30}	1,073,741,824
T	Tera	10^{12}	1,000,000,000,000
Ti	Tebi	2^{40}	1,099,511,627,776
P	Peta	10^{15}	1,000,000,000,000,000
Pi	Pebi	2^{50}	1,125,899,906,842,624

According to the new prefix standard, one mebibyte (1 MiB = 2^{20} B = 1,048,576 B), and one megabyte (1 MB = 10^6 B = 1,000,000 B). Because the new prefixes are not in widespread use (and they might never be) M in most cases can indicate both decimal *millions of bytes* and binary *megabytes*. Similarly, G is often used to refer to decimal *billions of bytes* and binary *gigabytes*. In general, memory values are expressed by using the binary values, although disk capacities can go either way. This often leads to confusion in reporting disk capacities because many manufacturers tend to use whichever value makes their products look better. For example, drive capacities are often rated in decimal billions (G - Giga), whereas most BIOS chips and operating system utilities, such as Windows' FDISK, rate the same drive in binary gigabytes (Gi -Gibi). Note also that when bits and bytes are used as part of some other measurement, the difference between bits and bytes is often distinguished by the use of a lower- or uppercase *B*. For example, megabits are typically abbreviated with a lowercase *b*, resulting in the abbreviation *Mbps* for *megabits per second*, whereas *MBps* indicates *megabytes per second*.

Areal Density

Areal density is often used as a technology growth-rate indicator for the hard disk drive industry. *Areal density* is defined as the product of the linear bits per inch (BPI), measured along the length of the tracks around the disk, multiplied by the number of tracks per inch (TPI), measured radially on the disk (see Figure 9.9). The results are expressed in units of megabits or gigabits per square inch (Mbit/sq.-inch or Gbit/sq.-inch) and are used as a measure of efficiency in drive recording technology. Current high-end 3.5-inch drives record at areal densities of 10Gbit/sq.-inch–20Gbit/sq.-inch. Prototype drives with densities as high as 40Gbit/sq.-inch now exist, which will allow 3.5-inch drives with capacities of 400GB or more in the next few years.

Drives record data in tracks, which are circular bands of data on the disk. Each track is divided into sectors. Figure 9.10 shows an actual floppy disk sprayed with magnetic developer (powdered iron) such that an image of the actual tracks and sectors can be clearly seen. The disk shown is a 5 1/4-inch 360KB floppy, which has 40 tracks per side, and each track is divided into 9 sectors. Note that each sector is delineated by gaps in the recording, which precede and postcede the track and sector headers (where ID and address information resides). You can clearly see the triple gap preceding the first sector, which includes the track and sector headers. Then following in a counterclockwise direction, you see each subsequent sector, preceded by gaps delineating the header for that sector. The area between the headers is where the sector data is written.

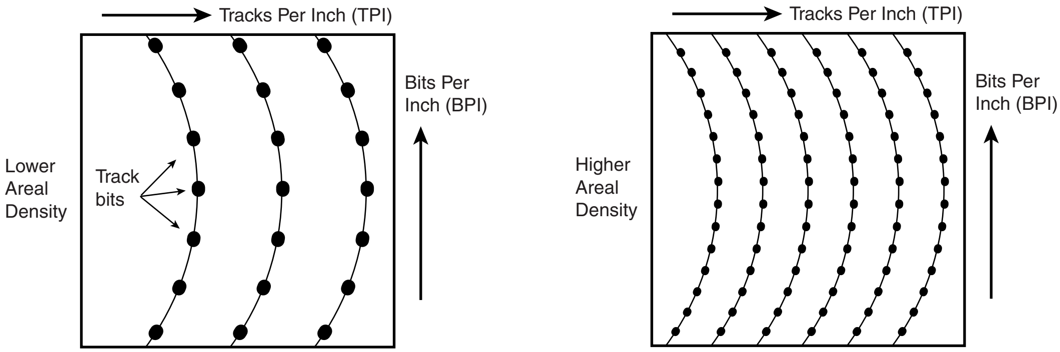

Figure 9.9 Areal density, combining tracks per inch and bits per inch.

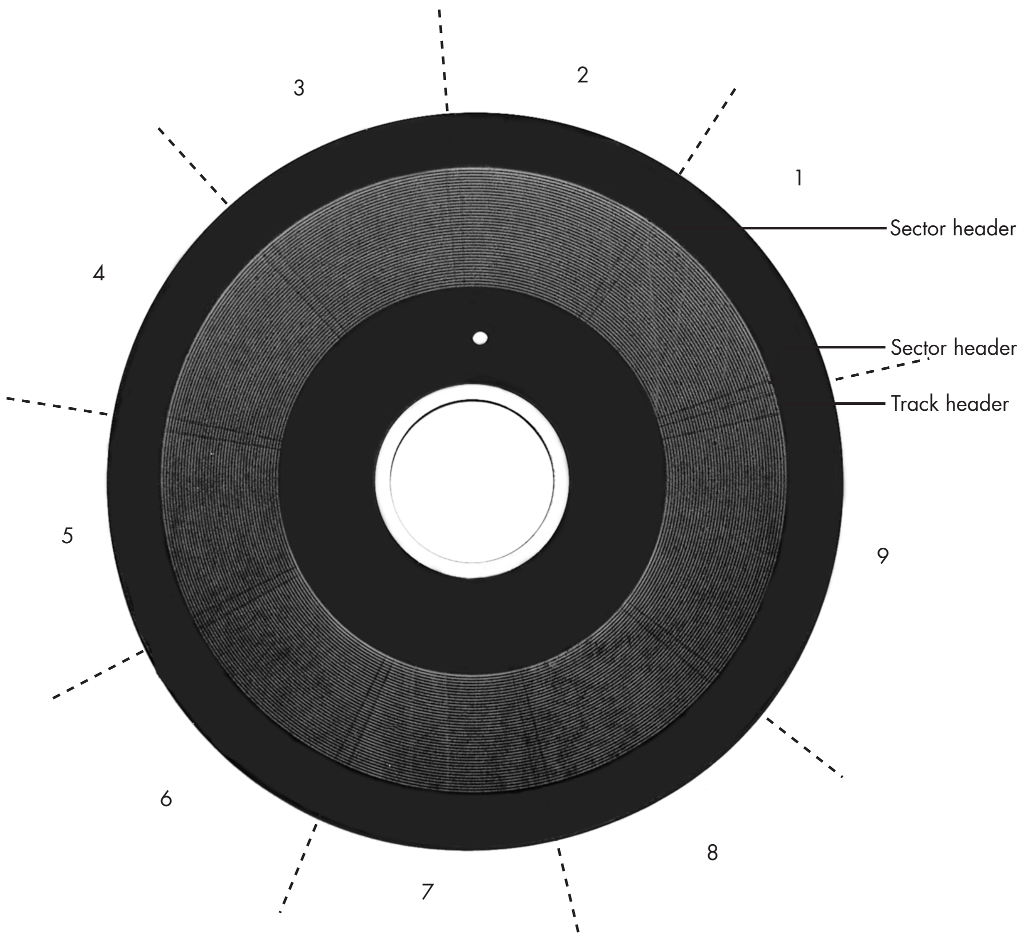

Figure 9.10 360KB floppy disk media sprayed with magnetic developer (powdered iron) showing the actual track and sector images.

Notice that sector 9 is longer than the rest; this is to enable rotational speed differences between drives, so that all the data can be written before running into the start of the track. Also notice that a good portion of the disk surface isn't used because it is simply impractical to have the heads travel in and out that far, and the difference in length between the sectors on the inner and outer tracks becomes more of a problem.

Areal density has been rising steadily since the first magnetic storage drive (IBM RAMAC) was introduced in 1956, initially at a growth rate of about 25% per year (doubling every four years), and since the early 1990s at a growth rate of about 60% per year (doubling every 1.5 years). The development and introduction of magneto-resistive in 1991 and giant magneto-resistive heads in 1997 propelled the increase in the areal density growth rate. In the 44+ years since the RAMAC drive was introduced, the areal density of magnetic storage has increased more than five million fold.

At the current growth rate, within the next five years or so, drive manufacturers will achieve areal densities of approximately 100Gbit/sq.-inch, which is considered near the point at which the superparamagnetic effect takes place. This is an effect in which the magnetic domains become so small that they are intrinsically unstable at room temperature. Techniques such as extremely high coercivity media and vertical polarity recording are projected to enable magnetic storage densities of 200Gbit/sq.-inch or more, but beyond that, scientists and engineers will have to look toward other technologies. One such technology being considered for the future is holographic storage, in which a laser writes data three-dimensionally in a crystal plate or cube.

Figure 9.11 shows how areal density has increased from when magnetic storage was first developed (1956 RAMAC) through the present time.

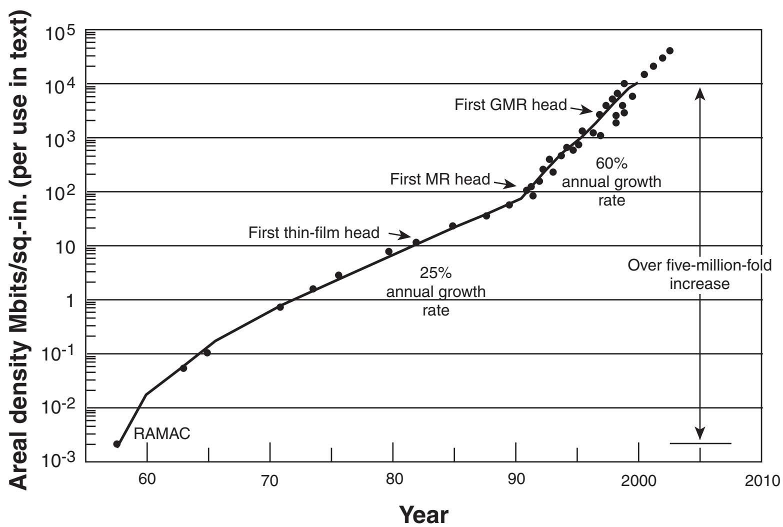

Figure 9.11 Evolution of areal density in magnetic disk storage.

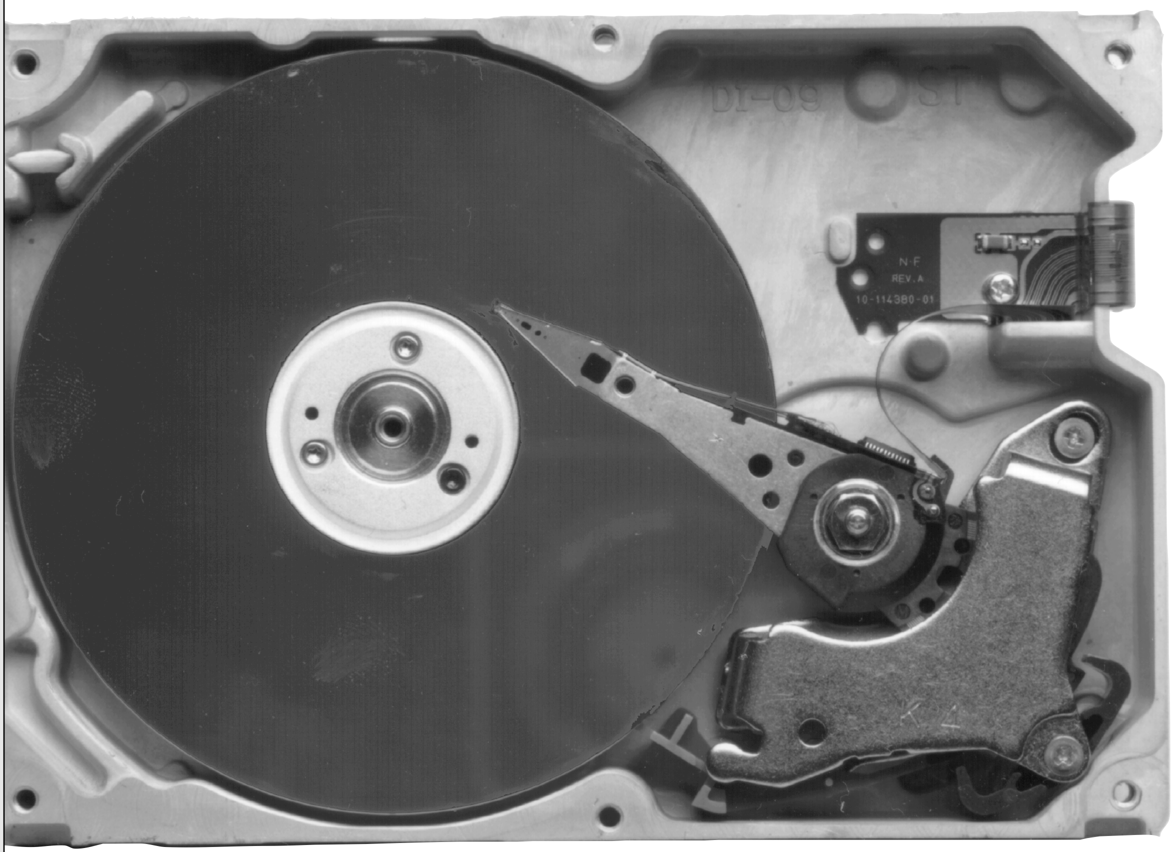
To increase areal density while maintaining the same external drive form factors, drive manufacturers have developed media and head technologies to support these higher areal densities, such as ceramic/glass platters, GMR heads, pseudo-contact recording, and PRML electronics, as discussed earlier in this chapter. The primary challenge in achieving higher densities is manufacturing drive heads and disks to operate at closer tolerances. Improvements in tolerances and the use of more platters in a given form factor continue to fuel improvements in drive capacity, but drive makers continue to seek even greater capacity increases, both by improving current technologies and by developing new ones.

To fit more data on a platter of a given size, the tracks must be placed closer together, and the heads must be capable of achieving greater precision in their placements over the tracks. This also means that as hard disk capacities increase, heads must float ever closer to the disk surface during operation. The gap between the head and disk is as close as 10 nanometers (0.01 microns) in some drives, which is approximately the thickness of a cell membrane. By comparison, a human hair is typically 80 microns in diameter, which is 8,000 times thicker than the gap between the head and disk in some drives. The prospect of actual contact or near contact recording is being considered for future drives to further increase density.

CHAPTER 10

Hard Disk Storage



Definition of a Hard Disk

To many users, the hard disk drive is the most important and yet the most mysterious part of a computer system. A *hard disk drive* is a sealed unit that a PC uses for nonvolatile data storage. *Nonvolatile*, or semi-permanent, storage means that the storage device retains the data even when no power is supplied to the computer. Because the hard disk drive is expected to retain data until deliberately erased or overwritten, the hard drive is used to store crucial programming and data. As a result, when the hard disk fails, the consequences are usually very serious. To maintain, service, and upgrade a PC system properly, you must understand how the hard disk functions.

A hard disk drive contains rigid, disk-shaped platters, usually constructed of aluminum or glass (see Figure 10.1). Unlike floppy disks, the platters cannot bend or flex—hence the term *hard disk*. In most hard disk drives, you cannot remove the platters, which is why they are sometimes called *fixed* disk drives. Removable hard disk drives are also available. Sometimes this term refers to a device in which the entire drive unit (that is, the disk and the drive) is removable, but it is more commonly used to refer to cartridge drives, where the platters are contained in a removable cartridge.

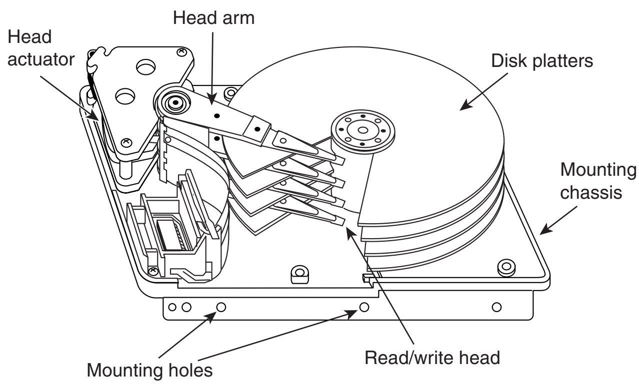


Figure 10.1 Hard disk heads and platters.

Note

Hard disk drives are sometimes referred to as *Winchester drives*. This term dates back to 1973, when IBM introduced the model 3340 drive, which had 30MB of fixed platter and 30MB of removable platter storage on separate spindles. The drive was codenamed Winchester by project leader Ken Haughton, because the original capacity designation (30-30) sounded like the popular .30-30 (caliber-grains of charge) cartridge used by the Winchester 94 rifle introduced in 1895. The original 3340 "Winchester" drive was the first to use a sealed head/disk assembly, and the name has since been applied to all subsequent drives with similar technology.

Hard Drive Advancements

In the almost 20 years that hard disks have commonly been used in PC systems, they have undergone tremendous changes. To give you an idea of how far hard drives have come in that time, I've outlined some of the more profound changes in PC hard disk storage:

- Maximum storage capacities have increased from the 5MB and 10MB 5 1/4-inch full-height drives available in 1982 to 180GB or more for even smaller 3 1/2-inch half-height drives (Seagate Barracuda 180), and 32GB or more for notebook system 2 1/2-inch drives (IBM

Travelstar 32GH) that are 12.5mm (or less) in height. Hard drives smaller than 10GB are rare in today's desktop personal computers.

- Data transfer rates from the media (sustained transfer rates) have increased from 85KB to 102KB/sec for the original IBM XT in 1983 to an average of 51.15MB/sec or more for the fastest drives today (Seagate Cheetah 73LP).
- Average seek times (how long it takes to move the heads to a particular cylinder) have decreased from more than 85ms (milliseconds) for the 10MB XT hard disk in 1983 to 4.2ms or less for some of the fastest drives today (Seagate Cheetah X15).
- In 1982, a 10MB drive cost more than $1,500 ($150 per megabyte). Today, the cost of hard drives has dropped to one-half cent per megabyte or less!

Hard Disk Drive Operation

The basic physical construction of a hard disk drive consists of spinning disks with heads that move over the disks and store data in tracks and sectors. The heads read and write data in concentric rings called *tracks*, which are divided into segments called *sectors*, which normally store 512 bytes each (see Figure 10.2).

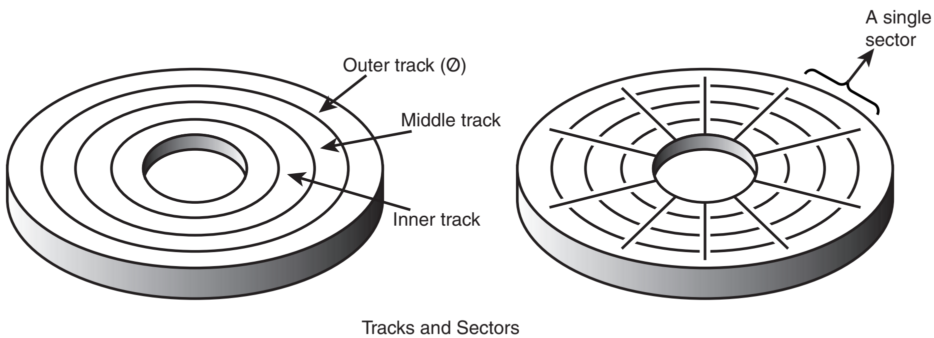

Figure 10.2 The tracks and sectors on a disk.

Hard disk drives usually have multiple disks, called *platters*, that are stacked on top of each other and spin in unison, each with two sides on which the drive stores data. Most drives have two or three platters, resulting in four or six sides, but some PC hard disks have up to 12 platters and 24 sides with 24 heads to read them (Seagate Barracuda 180). The identically aligned tracks on each side of every platter together make up a cylinder (see Figure 10.3). A hard disk drive normally has one head per platter side, with all the heads mounted on a common carrier device or rack. The heads move radially across the disk in unison; they cannot move independently because they are mounted on the same carrier or rack, called an *actuator*.

Originally, most hard disks spun at 3,600rpm—approximately 10 times faster than a floppy disk drive. For many years, 3,600rpm was pretty much a constant among hard drives. Now, however, most drives spin the disks even faster. While speeds can vary, most modern drives spin the platters at 4,200; 5,400; 7,200; 10,000; or 15,000rpm. High rotational speeds combined with a fast head-positioning mechanism and more sectors per track are what make one hard disk faster than another.

The heads in most hard disk drives do not (and should not!) touch the platters during normal operation. When the heads are powered off, however, in most drives they land on the platters as they stop spinning. While the drive is running, a very thin cushion of air keeps each head suspended a short distance above or below the platter. If the air cushion is disturbed by a particle of dust or a shock, the head can come into contact with the platter while it is spinning at full speed. When contact with the spinning platters is forceful enough to do damage, the event is called a *head crash*. The result of a head crash can be anything from a few lost bytes of data to a completely ruined drive. Most drives have special lubricants on the platters and hardened surfaces that can withstand the daily “takeoffs and landings” as well as more severe abuse.

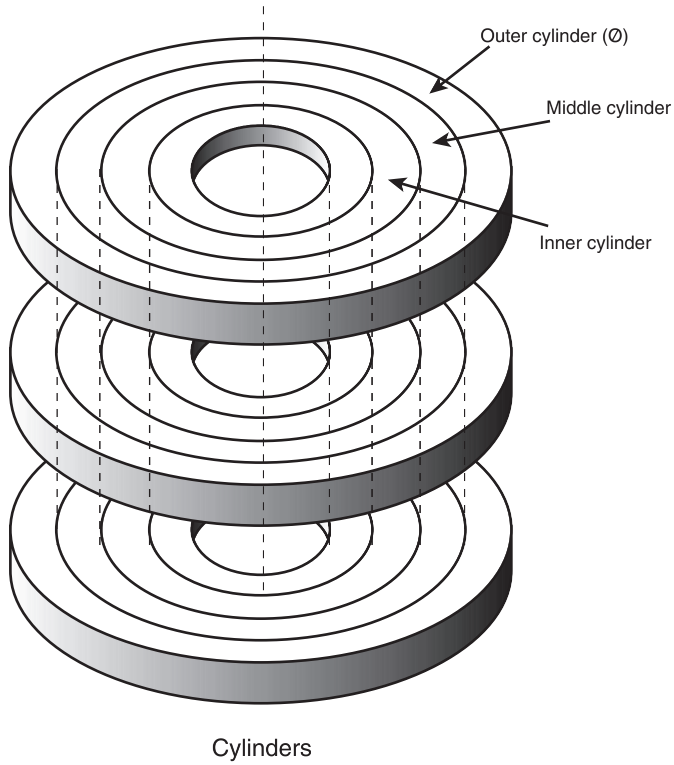

Figure 10.3 Hard disk cylinders.

Because the platter assemblies are sealed and nonremovable, the track densities on the disk can be very high. Hard drives today have up to 38,000 or more TPI (tracks per inch) recorded on the media (IBM Travelstar 30GT). Head Disk Assemblies (HDAs), which contain the platters, are assembled and sealed in clean rooms under absolutely sanitary conditions. Because few companies repair HDAs, repair or replacement of the parts inside a sealed HDA can be expensive. Every hard disk ever made eventually fails. The only questions are when the failure will occur and whether your data is backed up.

Caution

It is strongly recommended that you do not even attempt to open a hard disk drive’s HDA unless you have the equipment and the expertise to make repairs inside. Most manufacturers deliberately make the HDA difficult to open, to discourage the intrepid do-it-yourselfer. Opening the HDA almost certainly voids the drive’s warranty.

Many PC users think that hard disks are fragile, and comparatively speaking, they are one of the more fragile components in your PC. In many of my PC Hardware and Troubleshooting or Data Recovery seminars, however, I have run various hard disks with the covers removed, and have even removed and installed the covers while the drives were operating! Those drives continue to store data perfectly to this day with their lids either on or off. Of course, I do not recommend that you try this with your own drives.

The Ultimate Hard Disk Drive Analogy

There is an old analogy that compares the interaction of the heads and the medium in a typical hard disk drive as being similar in scale to a 747 flying a few feet off the ground at cruising speed (500+ mph). I have heard this analogy used over and over again for years, and I've even used it in my seminars many times without checking to see whether the analogy is technically accurate with respect to modern hard drives. It isn't.

One highly inaccurate aspect of the 747 analogy has always bothered me—the use of an airplane of any type to describe the head-and-platter interaction. This analogy implies that the heads fly very low over the surface of the disk, but technically, this is not true. The heads do not fly at all in the traditional aerodynamic sense; instead, they float on a cushion of air that is being dragged around by the platters.

A much better analogy would use a hovercraft instead of an airplane; the action of a hovercraft much more closely emulates the action of the heads in a hard disk drive. Like a hovercraft, the drive heads rely somewhat on the shape of the bottom of the head to capture and control the cushion of air that keeps them floating over the disk. By nature, the cushion of air on which the heads float forms only in very close proximity to the platter, and is often called an *air bearing* by the disk drive industry.

I thought it was time to come up with a new analogy that more correctly describes the dimensions and speeds at which a hard disk drive operates today. I looked up the specifications on a specific hard disk drive, and then magnified and rescaled all the dimensions involved to make the head floating height equal to one inch. For my example, I used an IBM Deskstar 75GXP drive, which is a 75GB (formatted capacity), 3 1/2-inch ATA (AT Attachment interface) drive. The head sliders (called pico sliders) in this drive are about 0.049 inches long, 0.039 inches wide, and 0.012 inches high. They float on a cushion of air about 15 nanometers (nm or billionths of a meter) over the surface of the disk while traveling at an average speed of 53.55 miles per hour (figuring an average track diameter of about 2.5 inches). These heads read and write individual bits spaced only 2.56 micro-inches (millionths of an inch) apart, along tracks separated by only 35.27 micro-inches. The heads can move from one track to another in 8.5 milliseconds during an average seek.

To create my analogy, I magnified the scale to make the head floating height equal to 5 millimeters (about 0.2 inches). Because 5 millimeters is about 333,333 times greater than 15 nanometers (nm), I scaled up everything else by the same amount.

Magnified to such a scale, the heads in this typical hard disk would be about 1,361 feet long, 1,083 feet wide, and 333 feet high (the length and height are about equal to the Sears Tower if it were toppled over sideways). These skyscraper-sized heads would float on a cushion of air which to scale would be only 5mm thick (about 0.2 inches) while travelling at a speed of 17.8 million miles per hour (4,958 miles per second), all while reading data bits spaced a mere 0.85 inches apart on tracks separated by only 0.98 feet!

The forward scale speed of this imaginary head is difficult to comprehend, so I'll elaborate. The diameter of the Earth at the equator is 7,926 miles, which means a circumference of about 24,900 miles. At 4,958 miles per second, this imaginary skyscraper-sized head would circle the earth once every five seconds (at only two-tenths of an inch over the surface)! It would also read 231.33MB in one lap around this equatorial track.

There is also sideways velocity to consider. Because the average seek time of 8.5 milliseconds is defined as the time it takes to move the heads over one-third of the total tracks (about 9,241 tracks in this case), the heads could move sideways within a scale distance of 1.71 miles in that short time. This results in a scale seek velocity of more than 726,321mph, or 202 miles per second!

This analogy should give you a new appreciation of the technological marvel that the modern hard disk drive actually represents. It makes the old 747 analogy look rather pathetic (not to mention inaccurate), doesn't it?

Tracks and Sectors

A *track* is a single ring of data on one side of a disk. A disk track is too large to manage data effectively as a single storage unit. Many disk tracks can store 100,000 or more bytes of data, which would be very inefficient for storing small files. For that reason, tracks are divided into several numbered divisions known as sectors. These sectors represent arc-shaped pieces of the track.

Various types of disk drives split their disk tracks into different numbers of sectors, depending on the density of the tracks. For example, floppy disk formats use 8–36 sectors per track, although hard disks usually store data at a higher density and today can have 900 or more sectors per track physically. The sectors created by the standard formatting procedure on a PC system have a capacity of 512 bytes, which has been one constant throughout the history of the PC. One interesting phenomenon of the PC standard is that to be compatible with most older BIOS and drivers, drives will usually perform an internal translation to a logical 63 sectors per track.

The sectors on a track are numbered starting with 1, unlike the heads or cylinders that are numbered starting with 0. For example, a 1.44MB floppy disk contains 80 cylinders numbered 0–79 and two heads numbered 0 and 1, whereas each track on each cylinder has 18 sectors numbered 1–18.

When a disk is formatted, the formatting program creates ID areas before and after each sector's data that the disk controller uses for sector numbering and for identifying the start and end of each sector. These areas precede and follow each sector's data area and consume some of the disk's total storage capacity. This accounts for the difference between a disk's unformatted and formatted capacities. Note that most modern hard drives are sold preformatted and only advertise the formatted capacity. The unformatted capacity is usually not mentioned anymore. Another interesting development is that IBM and others now make drives with ID-less recording, which means that the sectors are recorded without ID marks before and after each sector. This means that more of the disk can be used for actual data.

Each sector on a disk normally has a prefix portion, or header, that identifies the start of the sector and contains the sector number, as well as a suffix portion, or trailer, that contains a checksum (which helps ensure the integrity of the data contents). Many newer drives omit this header and have what is called a No-ID recording, allowing more space for data.

Each sector contains 512 bytes of data. The low-level formatting process normally fills the data bytes with some specific value, such as F6h (hex), or some other repeating test pattern used by the drive manufacturer. Some patterns are more difficult for the drive to encode/decode, so these patterns normally are used when the manufacturer is testing the drive during initial formatting. A special test pattern might cause errors to surface that a normal data pattern would not show. This way, the manufacturer can more accurately identify marginal sectors during testing.

Note

The type of disk formatting discussed here is a physical or low-level format, not the high-level format you perform when you use the Windows 9x/Me/2000 Explorer or the DOS FORMAT program on a disk. See the section "Disk Formatting" later in this chapter to learn about the difference between these two types of formatting.

The sector headers and trailers are independent of the operating system, the file system, and the files stored on the drive. In addition to the headers and trailers, gaps exist within the sectors, between the sectors on each track, and also between tracks, but none of these gaps contain usable data space. The gaps are created during the low-level format process when the recording is turned off momentarily. They serve the same function as having gaps of no sound between the songs recorded on a cassette tape. The prefix, suffix, and gaps account for the lost space between the unformatted capacity of a disk and the formatted capacity. For example, a 4MB (unformatted) floppy disk (3 1/2-inch) has a capacity of 2.88MB when it is formatted, a 2MB (unformatted) floppy has a formatted capacity of 1.44MB, and an older 38MB unformatted capacity (for instance, Seagate ST-4038) hard disk has a capacity of only 32MB when it is formatted. Because the ATA/IDE and SCSI hard drives you purchase today are low-level formatted at the factory, the manufacturers now advertise only the formatted capacity. Even so, nearly all drives use some reserved space for managing the data that will be stored on the drive.

Thus, while I stated earlier that each disk sector is 512 bytes in size, this statement is technically not true. Each sector does allow for the storage of 512 bytes of data, but the data area is only a portion of the sector. Each sector on a disk typically occupies 571 bytes of the disk, of which only 512 bytes are available for the storage of user data. The actual number of bytes required for the sector header and trailer can vary from drive to drive, but this figure is typical. As mentioned earlier, though, many modern drives now use a No-ID recording scheme that virtually eliminates the storage overhead of the sector header information. You might find it helpful to think of each disk sector as being a page in a book. In a book, each page contains text, but the entire page is not filled with text; rather, each page has top, bottom, left, and right margins. Information such as chapter titles (track and cylinder numbers) and page numbers (sector numbers) is placed in the margins. The “margin” areas of a sector are created and written to during the low-level formatting process. Formatting also fills the data area of each sector with dummy values. After you perform a high-level format on the disk, the PC’s file system can write to the data area of each sector, but the sector header and trailer information cannot be altered during normal write operations unless the disk is low-level formatted again.

Table 10.1 shows the format for each track and sector on a typical hard disk drive with 17 sectors per track.

Table 10.1 Typical Disk Track/Sector Format Using ID Marks

Bytes	Name	Description
16	POST INDEX GAP	All 4Eh, at the track beginning after the Index mark.
The following sector data (shown between the lines in this table) is repeated as many times as there are sectors on the track.		
13	ID VFO LOCK	All 00h; synchronizes the VFO for the sector ID.
1	SYNC BYTE	A1h; notifies the controller that data follows.
1	ADDRESS MARK	FEh; defines that ID field data follows.
2	CYLINDER NUMBER	A value that defines the head actuator position.
1	HEAD NUMBER	A value that defines the particular head selected.
1	SECTOR NUMBER	A value that defines the sector.
2	CRC	Cyclic Redundancy Check to verify ID data.
3	WRITE TURN-ON GAP	00h written by format to isolate the ID from DATA.
13	DATA SYNC VFO LOCK	All 00h; synchronizes the VFO for the DATA.
1	SYNC BYTE	A1h; notifies the controller that data follows.
1	ADDRESS MARK	F8h; defines that user DATA field follows.

Table 10.1 Continued

Bytes	Name	Description
512	DATA	The area for user DATA.
2	CRC	Cyclic Redundancy Check to verify DATA.
3	WRITE TURN-OFF GAP	00h; written by DATA update to isolate DATA.
15	INTER-RECORD GAP	All 00h; a buffer for spindle speed variation.
693	PRE-INDEX GAP	All 4Eh, at track end before Index mark.

571 = Total bytes per sector; 512 = Data (usable) bytes per sector

Note: "All XXh" indicates that field will be filled with XXh bytes.

As you can see, the usable space for data on each track is about 15% less than its total unformatted capacity. This is true for most disks, although the percentage can vary slightly, depending on how many sectors exist per track. The following paragraphs detail each piece of the sector data listed in Table 10.1.

The POST INDEX GAP provides a head-switching recovery period, so when switching from one track to another, the heads can read sequential sectors without waiting for an additional revolution of the disk. Because the disk is continuously spinning and the heads take some small amount of time to move radially from track to track, reading consecutive sectors on two different tracks, one right after the other, is not possible. By the time the head moves to the new track, the beginning of the second sector has already spun past it. Leaving a gap between sectors provides the heads with time to move to another track.

In some drives, this gap does not provide sufficient time for the heads to move. When this is the case, a drive can gain additional time by skewing the sectors on different tracks so the arrival of the first sector is delayed. In other words, the low-level formatting process offsets the sector numbering, so instead of the same numbered sectors on each track being adjacent to each other, Sector 9 on one track might be next to Sector 8 of the next track, which is next to Sector 7 on the next, and so forth. The optimum skew value is based on the rotational speed of the disk as compared to the lateral speed of the heads.

Note

At one time, the head skew was a parameter you could set yourself while low-level formatting a drive. Today's ATA/IDE and SCSI drives are low-level formatted at the factory with the optimum skew values.

The Sector ID data consists of the Cylinder, Head, and Sector Number fields, as well as a CRC field used to verify the ID data. Most controllers use bit 7 of the Head Number field to mark a sector as bad during a low-level format or surface analysis. This convention is not absolute, however. Some controllers use other methods to mark a bad sector, but usually the mark involves one of the ID fields.

The WRITE TURN-ON GAP follows the ID field's CRC bytes and provides a pad to ensure a proper recording of the user data area that follows, as well as to enable full recovery of the ID CRC.

The user DATA field consists of all 512 bytes of data stored in the sector. This field is followed by a CRC field to verify the data. Although many controllers use two bytes of CRC here, the controller might implement a longer Error Correction Code (ECC) that requires more than two CRC bytes to store. The ECC data stored here provides the possibility of correcting errors in the DATA field as well as detecting them. The correction/detection capabilities depend on the ECC code the drive uses and its implementation by the controller. The WRITE TURN-OFF GAP is a pad that enables the ECC (CRC) bytes to be fully recovered.

The INTER-RECORD GAP provides a means to accommodate variances in drive spindle speeds. A track might have been formatted while the disk was running slightly more slowly than normal and then written to while the disk was running slightly more quickly than normal. In such cases, this gap prevents the accidental overwriting of any information in the next sector. The actual size of this padding varies, depending on the speed of the DATA disk's rotation when the track was formatted and each time the DATA field is updated.

The PRE-INDEX GAP enables speed tolerance over the entire track. This gap varies in size, depending on the variances in disk rotation speed and write-frequency tolerance at the time of formatting.

This sector prefix information is extremely important because it contains the numbering information that defines the cylinder, head, and sector. So this information—except the DATA field, DATA CRC bytes, and WRITE TURN-OFF GAP—is written only during a low-level format.

Disk Formatting

Two formatting procedures are required before you can write user data to a disk:

- Physical, or low-level formatting
- Logical, or high-level formatting

When you format a blank floppy disk, the Windows 9x/Me/2000 Explorer or the DOS `FORMAT` command performs both types of formats simultaneously. If the floppy was already formatted, DOS and Windows will default to doing only a high-level format.

A hard disk, however, requires two separate formatting operations. Moreover, a hard disk requires a third step, between the two formatting procedures, to write the partitioning information to the disk. Partitioning is required because a hard disk is designed to be used with more than one operating system. Using multiple operating systems on one hard drive is possible by separating the physical formatting in a procedure that is always the same, regardless of the operating system used and the high-level format (which is different for each operating system). Partitioning enables a single hard disk drive to run more than one type of operating system, or it can enable a single operating system to use the disk as several volumes or logical drives. A *volume* or *logical drive* is any section of the disk to which the operating system assigns a drive letter or name.

Consequently, preparing a hard disk drive for data storage involves three steps:

1. Low-level formatting (LLF)
2. Partitioning
3. High-level formatting (HLF)

Low-Level Formatting

During a low-level format, the formatting program divides the disk's tracks into a specific number of sectors, creating the intersector and intertrack gaps and recording the sector header and trailer information. The program also fills each sector's data area with a dummy byte value or a pattern of test values. For floppy disks, the number of sectors recorded on each track depends on the type of disk and drive. For hard disks, the number of sectors per track depends on the drive and the controller interface.

Originally, PC hard disk drives used a separate controller that took the form of an expansion card or was integrated into the motherboard. Because the controller could be used with various disk drives and might even have been made by a different manufacturer, some uniformity had to exist in the communications between the controller and the drive. For this reason, the number of sectors written to a track tended to be relatively consistent.

The original ST-506/412 MFM controllers always placed 17 sectors per track on a disk, although ST-506/412 controllers with RLL encoding increased the number of sectors to 25 or 26 per track; ESDI drives had 32 or more sectors per track. The ATA/IDE and SCSI drives found in PCs today can have anywhere from 17 to 900 or more sectors per track.

Virtually all ATA and SCSI drives use a technique called *zoned-bit recording*, which writes a variable number of sectors per track. Without zoned-bit recording, the number of sectors, and therefore bits, on each track is a constant. This means the actual number of bits per inch will vary. More bits per inch will exist on the inner tracks, and fewer will exist on the outer. The data rate and rotational speed will remain constant, as will the number of bits per track. Figure 10.4 shows a drive recorded with the same number of sectors per track.

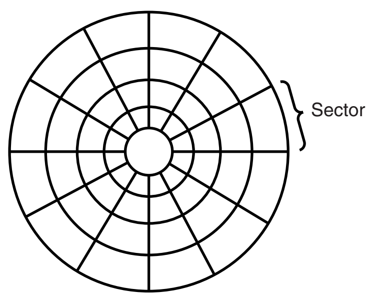

Figure 10.4 Standard recording, where the same number of sectors comprise every track.

A standard recording wastes capacity on the outer tracks, because it is longer and yet holds the same amount of data (more loosely spaced) as the inner tracks. One way to increase the capacity of a hard drive during the low-level format is to create more sectors on the disks' outer cylinders than on the inner ones. Because they have a larger circumference, the outer cylinders can hold more data. Drives without zoned-bit recording store the same amount of data on every cylinder, even though the tracks of the outer cylinders might be twice as long as those of the inner cylinders. The result is wasted storage capacity because the disk medium must be capable of storing data reliably at the same density as on the inner cylinders. When the number of sectors per track is fixed, as in older controllers, the drive capacity is limited by the density of the innermost (shortest) track.

Drives that use zoned-bit recording split the cylinders into groups called *zones*, with each successive zone having more sectors per track as you move outward from the center of the disk. All the cylinders in a particular zone have the same number of sectors per track. The number of zones varies with specific drives, but most drives have 10 or more zones.

Figure 10.5 shows a drive with zoned-bit recording.

Another effect of zoned-bit recording is that transfer speeds vary depending on which zone the heads are in. A drive with zoned-bit recording still spins at a constant speed; because more sectors exist per track in the outer zones, however, data transfer is fastest there. Consequently, data transfer is slowest when reading or writing to the inner zones. That is why virtually all drives today report minimum and maximum sustained transfer rates, which depend on where on the drive you are reading from or writing to.

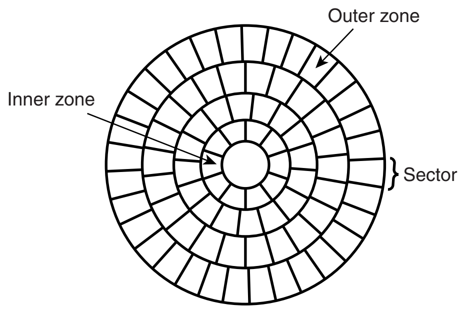

Figure 10.5 Zoned-bit recording, where the number of sectors per track increases within each zone, moving out from the center.

As an example, see Table 10.2, which shows the zones defined for an IBM Travelstar 32GH 2 1/2-inch notebook drive, the sectors per track for each zone, and the resulting data transfer rate.

Table 10.2 Zoned Bit Recording Information for the IBM Travelstar 32GH 32GB 2 1/2-inch Hard Disk Drive

Zone	Sectors per Track	Data Transfer Rate (MB/sec)	Bytes per Track	Sectors per Zone
0	617	28.49	315,904	835,418
1	598	27.60	306,005	809,241
2	578	26.70	296,107	783,063
3	559	25.81	286,208	756,886
4	540	24.92	276,309	730,709
5	520	24.03	266,411	704,531
6	501	23.13	256,512	678,354
7	482	22.24	246,613	652,177
8	462	21.35	236,715	625,999
9	443	20.46	226,816	599,822
10	424	19.56	216,917	573,645
11	404	18.67	207,019	547,467
12	385	17.78	197,120	521,290
13	366	16.88	187,221	495,113
14	346	15.99	177,323	468,935
15	327	15.10	167,424	442,758

21,664 Total Tracks; 16 Zones; 1,354 Tracks per Zone

512 Bytes per Sector; 5,411 rpm; 10,225,408 Total Sectors per Side

This drive has a total of 21,664 tracks on each platter surface and, as you can see, the tracks are divided into 16 zones of 1,354 tracks each. It is not essential for all the zones to be the same size; this is simply how this drive is arranged. Zone 0 consists of the outermost 1,354 tracks, which are the longest and contain the most sectors: 617. Because each sector is 512 bytes, each track in this zone can therefore provide about 315,904 bytes of user data storage, although the 327 sector tracks in zone 15 can hold only 167,424 bytes.

Thus, with zoned-bit recording, each platter surface in this disk drive contains 10,225,408 sectors, for a storage capacity of 5,235MB per side. Without zoned-bit recording, the number of sectors per track would be limited to 327 over the entire surface of each platter, for a total of 7,084,128 sectors, storing 3,627MB. Zoned-bit recording, therefore, provides a 44% increase in the storage capacity of this particular drive.

Notice also the difference in the data transfer rates for each of the zones. The tracks in the outermost zone (0) yield a transfer rate of 28.49MB/sec, which is 89% higher than the 15.10MB/sec of the innermost zone (15). This is one reason you might notice huge discrepancies in the results produced by disk drive benchmark programs. A test that reads or writes files on the outer tracks of the disk naturally yields far better results than one conducted on the inner tracks. It might appear as though your drive is running more slowly, when the problem is actually that the test results you are comparing stem from disk activity on different zones.

Another thing to note is that this drive conforms to the ATA-5 specification and is capable of running in Ultra-ATA/66 mode (also called UDMA-66), which implies a transfer speed of 66MB/sec. As you can see, that is entirely theoretical because the true *media transfer speed* of this drive varies between about 15MB/sec and 28MB/sec, averaging about 21.8MB/sec overall. The interface transfer rate is just that: what the interface is capable of. It has little bearing on the actual capabilities of the drive.

Drives with separate controllers used in the past could not handle zoned-bit recording because no standard way existed to communicate information about the zones from the drive to the controller.

With SCSI and ATA disks, however, formatting individual tracks with different numbers of sectors became possible because these drives have the disk controller built in. The built-in controllers on these drives are fully aware of the zoning algorithm and can translate the physical Cylinder, Head, and Sector numbers to logical Cylinder, Head, and Sector numbers so the drive appears to have the same number of sectors on each track. Because the PC BIOS is designed to handle only a single number of sectors per track throughout the entire drive, a zoned drive must run by using a sector translation scheme.

The use of zoned-bit recording enables drive manufacturers to increase the capacity of their hard drives by 20%–50% compared with a fixed–sector-per-track arrangement. All modern ATA (IDE) and SCSI drives today use zoned-bit recording.

Partitioning

Creating a partition on a hard disk drive enables it to support separate file systems, each in its own partition.

Each file system can then use its own method to allocate file space in logical units called *clusters* or *allocation units*. Every hard disk drive must have at least one partition on it and can have up to four partitions, each of which can support the same or different type file systems. Three common file systems are used by PC operating systems today:

- *FAT (File Allocation Table).* The standard file system supported by DOS, Windows 9x/Me/2000, and Windows NT. FAT partitions support filenames of 11 characters maximum (8 characters+ 3-character extension) under DOS, and 255 characters under Windows 9x/Me/2000 or Windows NT 4.0 (or later). The standard FAT file system uses 12- or 16-bit numbers to identify clusters, resulting in a maximum volume size of 2GB.

  Using FDISK, you can create only two physical FAT partitions on a hard disk drive—primary and extended—but you can subdivide the extended partition into as many as 25 logical volumes. Alternative partitioning programs, such as Partition Magic, can create up to four primary partitions or three primary and one extended.

- *FAT32 (File Allocation Table, 32-bit).* An optional file system supported by Windows 95 OSR2 (OEM Service Release 2), Windows 98, Windows Me, and Windows 2000.

  FAT32 uses 32-bit numbers to identify clusters, resulting in a maximum single volume size of 2TB or 2,048GB.

- *NTFS (Windows NT File System).* The native file system for Windows NT/2000 that supports filenames up to 256 characters long and partitions up to (a theoretical) 16 exabytes. NTFS also provides extended attributes and file system security features that do not exist in the FAT file system. Of these three file systems, the FAT file system still is by far the most popular and is accessible by nearly every operating system, which makes it the most compatible as well. FAT32 and NTFS provide additional features but are not universally accessible by other operating systems.

▶▶ See "FAT Disk Structures," p. 1316 and "FAT32," p. 1334.

Partitioning normally is accomplished by running the FDISK program that comes with your operating system. FDISK enables you to select the amount of space on the drive to use for a partition, from a single megabyte or 1% of the drive up to the entire capacity of the drive, or as much as the particular file system will allow. Normally, it is recommended to have as few partitions as possible, and many people (myself included) try to stick with only one or two at the most. This was more difficult before FAT32 because the maximum partition size for a FAT16 partition was only 2GB. With FAT32, the maximum partition size can be up to 2,048GB.

Caution

FDISK cannot be used to change the size of a partition; all it can do is remove or create partitions. The act of removing or creating a partition destroys any data that was contained in the partition or was on that part of the disk. To manipulate partitions without destroying data, you can use third-party utility programs, such as Partition Magic from PowerQuest or Partition Commander from V Communications.

After a drive is partitioned, each partition must then be high-level formatted by the operating system that will use it.

High-Level Formatting

During the high-level format, the operating system (such as Windows 9x/Me/2000, Windows NT, or DOS) writes the structures necessary for managing files and data on the disk. FAT partitions have a Volume Boot Sector (VBS), two copies of a file allocation table (FAT), and a root directory on each formatted logical drive. These data structures enable the operating system to manage the space on the disk, keep track of files, and even manage defective areas so they do not cause problems.

High-level formatting is not really a physical formatting of the drive, but rather the creation of a table of contents for the disk. In low-level formatting, which is the real physical formatting process, tracks and sectors are written on the disk. As mentioned, the DOS `FORMAT` command can perform both low-level and high-level format operations on a floppy disk, but it performs only the high-level format for a hard disk. Low-level formats of ATA and SCSI hard disk drives are performed by the manufacturer and should almost never be performed by the end user. The only time I low-level format ATA or SCSI drives is when I am attempting to repair a format that has become damaged (parts of the disk become unreadable), or in some cases when I want to wipe away all data on the drive.

Basic Hard Disk Drive Components

Many types of hard disk drives are on the market, but nearly all share the same basic physical components. Some differences might exist in the implementation of these components (and in the quality of the materials used to make them), but the operational characteristics of most drives are similar. The basic components of a typical hard disk drive are as follows (see Figure 10.6):

- Disk platters
- Read/write heads
- Head actuator mechanism
- Spindle motor (inside platter hub)
- Logic board (controller or Printed Circuit Board)
- Cables and connectors
- Configuration items (such as jumpers or switches)

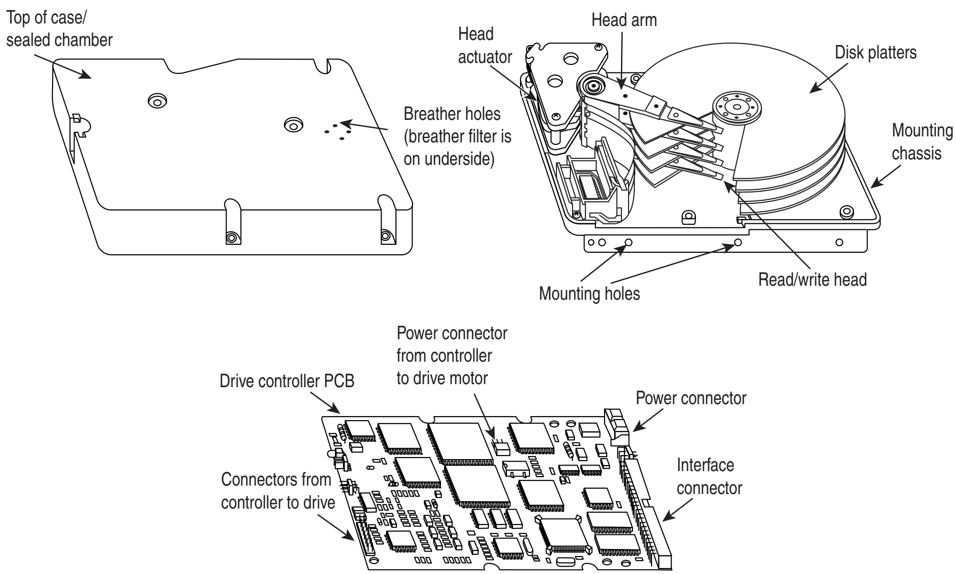

Figure 10.6 Typical hard disk drive components.

The platters, spindle motor, heads, and head actuator mechanisms usually are contained in a sealed chamber called the Head Disk Assembly (HDA). The HDA is usually treated as a single component; it is rarely opened. Other parts external to the drive's HDA, such as the logic boards, bezel, and other configuration or mounting hardware, can be disassembled from the drive.

Hard Disk Platters (Disks)

A hard disk drive has one or more platters, or disks. Hard disks for PC systems have been available in a number of form factors over the years. Normally, the physical size of a drive is expressed as the size of the platters. Following are the platter sizes that have been associated with PC hard disk drives:

- 5 1/4-inch (actually 130mm, or 5.12 inches)
- 3 1/2-inch (actually 95mm, or 3.74 inches)
- 2 1/2-inch (actually 65mm, or 2.56 inches)
- 1-inch (actually 34mm, or 1.33 inches)

Larger hard disk drives that have 8-inch, 14-inch, or even larger platters are available, but these drives are not used with PC systems. Currently, the 3 1/2-inch drives are the most popular for desktop and some portable systems, whereas the 2 1/2-inch and smaller drives are very popular in portable or notebook systems.

During 1998, IBM introduced a drive called the MicroDrive, which currently can store up to 1GB or more on a single platter about the size of a quarter! This type of drive can be used in information appliances, digital cameras, and anywhere else flash memory cards have been used.

Most hard disk drives have two or more platters, although some of the smaller drives used in portable systems have only one. The number of platters a drive can have is limited by the drive's vertical physical size. The maximum number of platters I have seen in any 3 1/2-inch drive is 12; however, most drives have 6 or fewer.

Platters have traditionally been made from an aluminum/magnesium alloy, which provides both strength and light weight. However, manufacturers' desire for higher and higher densities and smaller drives has led to the use of platters made of glass (or, more technically, a glass-ceramic composite). One such material, produced by the Dow Corning Corporation, is called MemCor. MemCor is composed of glass with ceramic implants, enabling it to resist cracking better than pure glass. Glass platters offer greater rigidity than metal (because metal can be bent and glass cannot) and can therefore be machined to one-half the thickness of conventional aluminum disks—sometimes less. Glass platters are also much more thermally stable than aluminum platters, which means they do not expand or contract very much with changes in temperature. Several hard disk drives made by companies such as IBM, Seagate, Toshiba, Areal Technology, and Maxtor currently use glass or glass-ceramic platters. For most manufacturers, glass disks will probably replace the standard aluminum/magnesium substrate over the next few years, especially in high-performance 2 1/2- and 3 1/2-inch drives.

Recording Media

No matter which substrate is used, the platters are covered with a thin layer of a magnetically retentive substance, called the *medium*, on which magnetic information is stored. Two popular types of magnetic media are used on hard disk platters:

- Oxide medium
- Thin-film medium

The oxide medium is made of various compounds, containing iron oxide as the active ingredient. The magnetic layer is created on the disk by coating the aluminum platter with a syrup containing iron-oxide particles. This syrup is spread across the disk by spinning the platters at high speed; centrifugal force causes the material to flow from the center of the platter to the outside, creating an even coating of the material on the platter. The surface is then cured and polished. Finally, a layer of material that protects and lubricates the surface is added and burnished smooth. The oxide coating is normally about 30 millionths of an inch thick. If you could peer into a drive with oxide-coated platters, you would see that the platters are brownish or amber.

As drive density increases, the magnetic medium needs to be thinner and more perfectly formed. The capabilities of oxide coatings have been exceeded by most higher-capacity drives. Because the oxide medium is very soft, disks that use it are subject to head-crash damage if the drive is jolted during operation. Most older drives, especially those sold as low-end models, use oxide media on the drive platters. Oxide media, which have been used since 1955, remained popular because of their relatively low cost and ease of application. Today, however, very few drives use oxide media.

The thin-film medium is thinner, harder, and more perfectly formed than oxide medium. Thin film was developed as a high-performance medium that enabled a new generation of drives to have lower head-floating heights, which in turn made increases in drive density possible. Originally, thin-film media were used only in higher-capacity or higher-quality drive systems, but today, virtually all drives use thin-film media.

The thin-film medium is aptly named. The coating is much thinner than can be achieved by the oxide-coating method. Thin-film media are also known as plated, or sputtered, media because of the various processes used to deposit the thin film on the platters.

Thin-film plated media are manufactured by depositing the magnetic medium on the disk with an electroplating mechanism, in much the same way that chrome plating is deposited on the bumper of a car. The aluminum/magnesium or glass platter is immersed in a series of chemical baths that coat the platter with several layers of metallic film. The magnetic medium layer itself is a cobalt alloy about 1 µ-inch thick.

Thin-film sputtered media are created by first coating the aluminum platters with a layer of nickel phosphorus and then applying the cobalt-alloy magnetic material in a continuous vacuum-deposition process called *sputtering*. This process deposits magnetic layers as thin as 1 µ-inch or less on the disk, in a fashion similar to the way that silicon wafers are coated with metallic films in the semiconductor industry. The same sputtering technique is then used again to lay down an extremely hard, 1 µ-inch protective carbon coating. The need for a near-perfect vacuum makes sputtering the most expensive of the processes described here.

The surface of a sputtered platter contains magnetic layers as thin as 1 µ-inch. Because this surface also is very smooth, the head can float more closely to the disk surface than was possible previously. Floating heights as small as 15nm (nanometers, or about 0.6 µ-inch) above the surface are possible. When the head is closer to the platter, the density of the magnetic flux transitions can be increased to provide greater storage capacity. Additionally, the increased intensity of the magnetic field during a closer-proximity read provides the higher signal amplitudes needed for good signal-to-noise performance.

Both the sputtering and plating processes result in a very thin, hard film of magnetic medium on the platters. Because the thin-film medium is so hard, it has a better chance of surviving contact with the heads at high speed. In fact, modern thin-film media are virtually uncrashable. If you could open a drive to peek at the platters, you would see that platters coated with the thin-film medium look like mirrors.

Read/Write Heads

A hard disk drive usually has one read/write head for each platter surface (meaning that each platter has two sets of read/write heads—one for the top side and one for the bottom side). These heads are connected, or ganged, on a single movement mechanism. The heads, therefore, move across the platters in unison.

Mechanically, read/write heads are simple. Each head is on an actuator arm that is spring-loaded to force the head into contact with a platter. Few people realize that each platter actually is "squeezed" by the heads above and below it. If you could open a drive safely and lift the top head with your finger, the head would snap back down into the platter when you released it. If you could pull down on one of the heads below a platter, the spring tension would cause it to snap back up into the platter when you released it.

Figure 10.7 shows a typical hard disk head-actuator assembly from a voice coil drive.

When the drive is at rest, the heads are forced into direct contact with the platters by spring tension, but when the drive is spinning at full speed, air pressure develops below the heads and lifts them off the surface of the platter. On a drive spinning at full speed, the distance between the heads and the platter can be anywhere from 0.5 to 5 µ-inch or more in a modern drive.

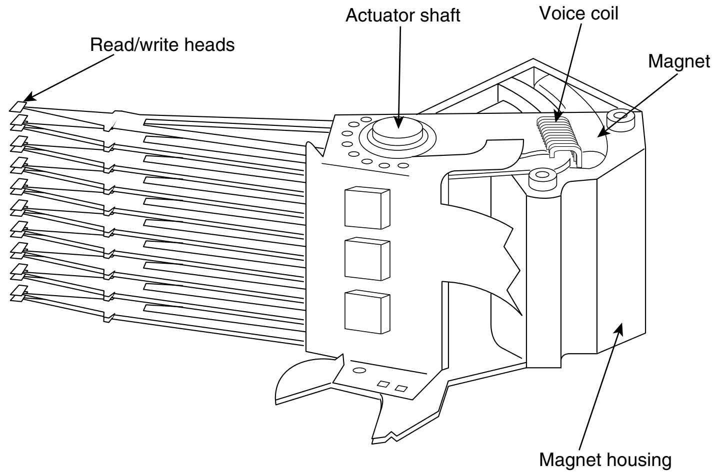

Figure 10.7 Read/write heads and rotary voice coil actuator assembly.

In the early 1960s, hard disk drive recording heads operated at floating heights as large as 200–300 μ-inch; today's drive heads are designed to float as low as 10nm (nanometers) or 0.4 μ-inch above the surface of the disk. To support higher densities in future drives, the physical separation between the head and disk is expected to drop even further, such that on some drives there will even be contact with the platter surface. New media and head designs will make full or partial contact recording possible.

Caution

The small size of the gap between the platters and the heads is why you should never open the disk drive's HDA except in a clean-room environment. Any particle of dust or dirt that gets into this mechanism could cause the heads to read improperly or possibly even to strike the platters while the drive is running at full speed. The latter event could scratch the platter or the head.

To ensure the cleanliness of the interior of the drive, the HDA is assembled in a class-100 or better clean room. This specification means that a cubic foot of air cannot contain more than 100 particles that measure up to 0.5 microns (19.7 μ-inch). A single person breathing while standing motionless spews out 500 such particles in a single minute! These rooms contain special air-filtration systems that continuously evacuate and refresh the air. A drive's HDA should not be opened unless it is inside such a room.

Although maintaining a clean-room environment might seem to be expensive, many companies manufacture tabletop or bench-size clean rooms that sell for only a few thousand dollars. Some of these devices operate like a glove box; the operator first inserts the drive and any tools required, and then closes the box and turns on the filtration system. Inside the box, a clean-room environment is maintained, and a technician can use the built-in gloves to work on the drive.

In other clean-room variations, the operator stands at a bench where a forced-air curtain maintains a clean environment on the bench top. The technician can walk in and out of the clean-room field by walking through the air curtain. This air curtain is very similar to the curtain of air used in some stores and warehouses to prevent heat from escaping in the winter while leaving a passage wide open.

Because the clean environment is expensive to produce, few companies, except those that manufacture the drives, are properly equipped to service hard disk drives.

Read/Write Head Designs

As disk drive technology has evolved, so has the design of the read/write head. The earliest heads were simple iron cores with coil windings (electromagnets). By today's standards, the original head designs were enormous in physical size and operated at very low recording densities. Over the years, head designs have evolved from the first simple Ferrite Core designs into the Magneto-Resistive and Giant Magneto-Resistive types available today.

For more information on the various head designs, see Chapter 9, "Magnetic Storage Principles."

Head Actuator Mechanisms

Possibly more important than the heads themselves is the mechanical system that moves them: the head actuator. This mechanism moves the heads across the disk and positions them accurately above the desired cylinder. Many variations on head actuator mechanisms are in use, but all fall into one of two basic categories:

- Stepper motor actuators
- Voice coil actuators

The use of one or the other type of actuator has profound effects on a drive's performance and reliability. The effects are not limited to speed; they also include accuracy, sensitivity to temperature, position, vibration, and overall reliability. The head actuator is the single most important specification in the drive, and the type of head actuator mechanism in a drive tells you a great deal about the drive's performance and reliability characteristics. Table 10.3 shows the two types of hard disk drive head actuators and the affected performance characteristics.

Table 10.3 Characteristics of Stepper Motor Versus Voice Coil Drives

Characteristic	Stepper Motor	Voice Coil
Relative access speed	Slow	Fast
Temperature sensitive	Yes (very)	No
Positionally sensitive	Yes	No
Automatic head parking	Not usually	Yes
Preventive maintenance	Periodic reformat	None required
Relative reliability	Poor	Excellent

Generally, a stepper motor drive has a slower average access rating, is temperature sensitive during read and write operations, is sensitive to physical orientation during read and write operations, does not automatically park its heads above a save zone during power-down, and usually requires annual or biannual reformats to realign the sector data with the sector header information due to mistracking. To put it bluntly, a drive equipped with a stepper motor actuator is much less reliable (by a large margin) than a drive equipped with a voice coil actuator.

Floppy disk drives position their heads by using a stepper motor actuator. The accuracy of the stepper mechanism is suited to a floppy disk drive because the track densities usually are nowhere near those of a hard disk. The track density of a 1.44MB floppy disk is 135 tracks per inch, whereas hard disk drives have densities of more than 5,000 tracks per inch. Virtually all the hard disk drives being manufactured today use voice coil actuators because stepper motors cannot achieve the degree of accuracy necessary.

Stepper Motor Actuators

A stepper motor is an electrical motor that can "step," or move from position to position, with mechanical detents or click-stop positions. If you were to grip the spindle of one of these motors and spin it manually, you would hear a clicking or buzzing sound as the motor passed each detent position with a soft click.

Stepper motors cannot position themselves between step positions; they can stop only at the predetermined detent positions. The motors are small (between 1 and 3 inches) and can be square, cylindrical, or flat. Stepper motors are outside the sealed HDA, although the spindle of the motor penetrates the HDA through a sealed hole.

Stepper motor mechanisms are affected by a variety of problems; the greatest problem is temperature. As the drive platters heat and cool, they expand and contract, and the tracks on the platters move in relation to a predetermined track position. The stepper mechanism cannot move in increments of less than a single track to correct for these temperature-induced errors. The drive positions the heads to a particular cylinder according to a predetermined number of steps from the stepper motor, with no room for nuance.

Figure 10.8 shows a common stepper motor design, where a split metal band is used to transfer the movement from the rotating motor shaft to the head actuator itself.

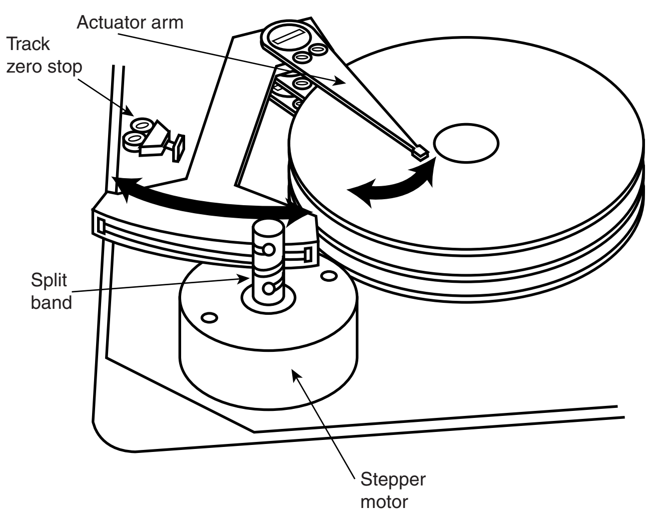

Figure 10.8 A stepper motor actuator.

Voice Coil Actuators

The voice coil actuators used in virtually all hard disk drives made today—unlike stepper motor actuators—use a feedback signal from the drive to accurately determine the head positions and adjust them, if necessary. This arrangement provides significantly greater performance, accuracy, and reliability than traditional stepper motor actuator designs.

A voice coil actuator works by pure electromagnetic force. The construction of the mechanism is similar to that of a typical audio speaker, from which the term *voice coil* is derived. An audio speaker uses a stationary magnet surrounded by a voice coil, which is connected to the speaker's paper cone. Energizing the coil causes it to move relative to the stationary magnet, which produces sound from the cone. In a typical hard disk drive's voice coil system, the electromagnetic coil is attached to the end of the head rack and placed near a stationary magnet. No physical contact occurs between the coil and the magnet; instead, the coil moves by pure magnetic force. As the electromagnetic coils are energized, they attract or repulse the stationary magnet and move the head rack. Systems like these are extremely quick and efficient and usually much quieter than systems driven by stepper motors.

Unlike a stepper motor, a voice coil actuator has no click-stops, or detent positions; rather, a special guidance system stops the head rack above a particular cylinder. Because it has no detents, the voice coil actuator can slide the heads in and out smoothly to any position desired. Voice coil actuators use a guidance mechanism called a *servo* to tell the actuator where the heads are in relation to the cylinders and to place the heads accurately at the desired positions. This positioning system often is called a *closed loop feedback mechanism*. It works by sending the index (or servo) signal to the positioning electronics, which return a feedback signal that is used to position the heads accurately. The system also is called *servo-controlled*, which refers to the index or servo information that is used to dictate or control head-positioning accuracy.

A voice coil actuator with servo control is not affected by temperature changes, as a stepper motor is. When temperature changes cause the disk platters to expand or contract, the voice coil system compensates automatically because it never positions the heads in predetermined track positions. Rather, the voice coil system searches for the specific track, guided by the prewritten servo information, and then positions the head rack precisely above the desired track, wherever it happens to be. Because of the continuous feedback of servo information, the heads adjust to the current position of the track at all times. For example, as a drive warms up and the platters expand, the servo information enables the heads to "follow" the track. As a result, a voice coil actuator is sometimes called a *track following system*.

The two main types of voice-coil positioner mechanisms are

- Linear voice-coil actuators
- Rotary voice-coil actuators

The two types differ only in the physical arrangement of the magnets and coils.

A linear actuator (see Figure 10.9) moves the heads in and out over the platters in a straight line. The coil moves in and out on a track surrounded by the stationary magnets. The primary advantage of the linear design is that it eliminates the head *azimuth* variations that occur with rotary positioning systems. (Azimuth refers to the angular measurement of the head position relative to the tangent of a given cylinder.) A linear actuator does not rotate the head as it moves from one cylinder to another, thus eliminating this problem.

Although the linear actuator seems to be a good design, it has one fatal flaw: The devices are much too heavy. As drive performance has increased, the desire for lightweight actuator mechanisms has become very important. The lighter the mechanism, the faster it can accelerate and decelerate from one cylinder to another. Because they are much heavier than rotary actuators, linear actuators were popular only for a short time; they are virtually nonexistent in drives manufactured today.

Rotary actuators also use stationary magnets and a movable coil, but the coil is attached to the end of an actuator arm. As the coil moves relative to the stationary magnet, it swings the head arms in and out over the surface of the disk. The primary advantage of this mechanism is its light weight, which means that the heads can accelerate and decelerate very quickly, resulting in very fast average seek times. Because of the lever effect on the head arm, the heads move faster than the actuator, which also helps to improve access times. (Refer to Figure 10.7, which shows a rotary voice coil actuator.)

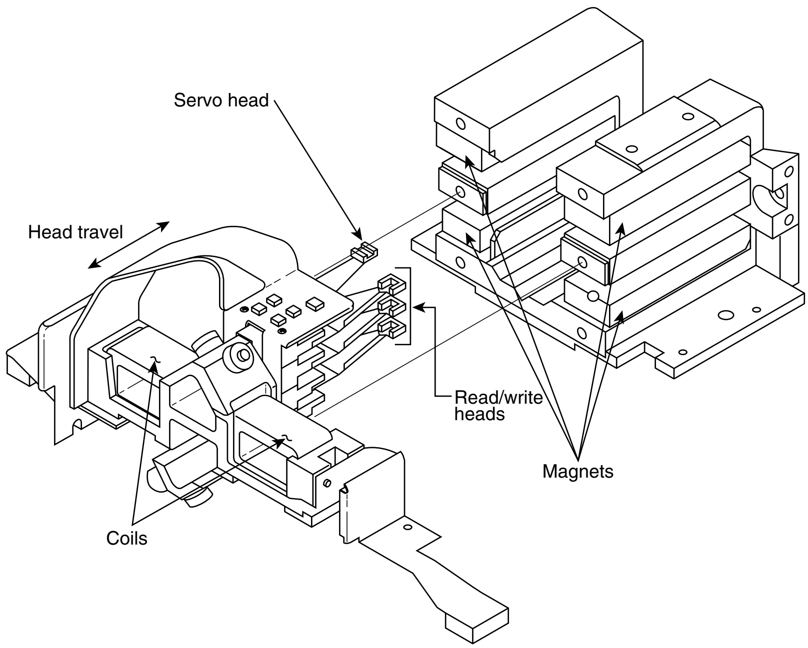

Figure 10.9 A linear voice coil actuator.

The disadvantage of a rotary system is that as the heads move from the outer to the inner cylinders, they rotate slightly with respect to the tangent of the cylinders. This rotation results in an azimuth error and is one reason why the area of the platter in which the cylinders are located is somewhat limited. By limiting the total motion of the actuator, the azimuth error is contained to within reasonable specifications. Virtually all voice coil drives today use rotary actuator systems.

Servo Mechanisms

Three servo mechanism designs have been used to control voice coil positioners over the years:

- Wedge servo
- Embedded servo
- Dedicated servo

The three designs are slightly different, but they accomplish the same basic task: They enable the head positioner to adjust continuously so it is precisely positioned above a given cylinder on the disk. The main difference between these servo designs is where the gray code information is actually written on the drive.

All servo mechanisms rely on special information that is written to the disk when it is manufactured. This information is usually in the form of a special code called a *gray code*. A gray code is a special binary notational system in which any two adjacent numbers are represented by a code that differs in only one bit place or column position. This system makes it easy for the head to read the information and quickly determine its precise position.

At the time of manufacture, a special machine called a servowriter writes the servo gray code on the disk. The servowriter is basically a jig that mechanically moves the heads to a given reference position and then writes the servo information at that position. Many servowriters are themselves guided by a laser-beam reference that calculates its own position by calculating distances in wavelengths of light. Because the servowriter must be capable of moving the heads mechanically, the process requires either that the lid of the drive be removed or that access be available through special access ports in the HDA. After the servowriting is complete, these ports are usually covered with sealing tape. You often see these tape-covered holes on the HDA, usually accompanied by warnings that you will void the warranty if you remove the tape. Because servowriting exposes the interior of the HDA, it requires a clean-room environment.

A servowriter is an expensive piece of machinery, costing up to $50,000 or more, and often must be custom-made for a particular make or model of drive. Some drive-repair companies have servowriting capability, which means they can rewrite the servo information on a drive if it becomes damaged. If a servowriter is not available, a drive with servo-code damage must be sent back to the drive manufacturer for the servo information to be rewritten.

Fortunately, damaging the servo information through disk read and write processes is impossible. Drives are designed so the heads cannot overwrite the servo information, even during a low-level format. One myth that has been circulating (especially with respect to ATA drives) is that you can damage the servo information by improper low-level formatting. This is not true. An improper low-level format can compromise the performance of the drive, but the servo information is totally protected and cannot be overwritten. Even so, the servo information on some drives can be damaged by a strong adjacent magnetic field or by jarring the drive while it is writing, causing the heads to move off track.

The track-following capabilities of a servo-controlled voice coil actuator eliminate the positioning errors that occur over time with stepper motor drives. Voice coil drives are not affected by conditions such as thermal expansion and contraction of the platters. In fact, many voice coil drives today perform a special thermal-recalibration procedure at predetermined intervals while they run. This procedure usually involves seeking the heads from cylinder 0 to some other cylinder one time for every head on the drive. As this sequence occurs, the control circuitry in the drive monitors how much the track positions have moved since the last time the sequence was performed, and a thermal-recalibration adjustment is calculated and stored in the drive's memory. This information is then used every time the drive positions the heads to ensure the most accurate positioning possible.

Most drives perform the thermal-recalibration sequence every 5 minutes for the first 30 minutes that the drive is powered on and then once every 25 minutes after that. With some drives, this thermal-recalibration sequence is very noticeable; the drive essentially stops what it is doing, and you hear rapid ticking for a second or so. Some people think this is an indication that their drive is having a problem reading something and perhaps is conducting a read retry, but this is not true. Most drives today (ATA and SCSI) employ this thermal-recalibration procedure to maintain positioning accuracy.

As multimedia applications grew in popularity, thermal recalibration became a problem with some manufacturers' drives. The thermal-recalibration sequence sometimes interrupted the transfer of a large data file, such as an audio or a video file, which resulted in audio or video playback jitter. Some companies released special A/V (audio visual) drives that hide the thermal-recalibration sequences so they never interrupt a file transfer. Most of the newer ATA and SCSI drives are A/V capable, which means that the thermal-recalibration sequences will not interrupt a transfer such as a video playback.

While we are on the subject of automatic drive functions, most of the drives that perform thermal-recalibration sequences also automatically perform a function called a *disk sweep*. Also called *wear leveling* by some manufacturers, this procedure is an automatic head seek that occurs after the drive has been idle for a period of time. The disk-sweep function moves the heads to a cylinder in the outer portion of the platters, which is where the head float-height is highest (because the head-to-platter velocity is highest). Then, if the drive continues to remain idle for another period, the heads move to another cylinder in this area, and the process continues indefinitely as long as the drive is powered on.

The disk-sweep function is designed to prevent the head from remaining stationary above one cylinder in the drive for too long, where friction between the head and platter eventually would dig a trench in the medium. Although the heads are not in direct contact with the medium, they are so close that the constant air pressure from the head floating above a single cylinder could cause friction and excessive wear. Figure 10.10 shows both a wedge and an embedded servo.

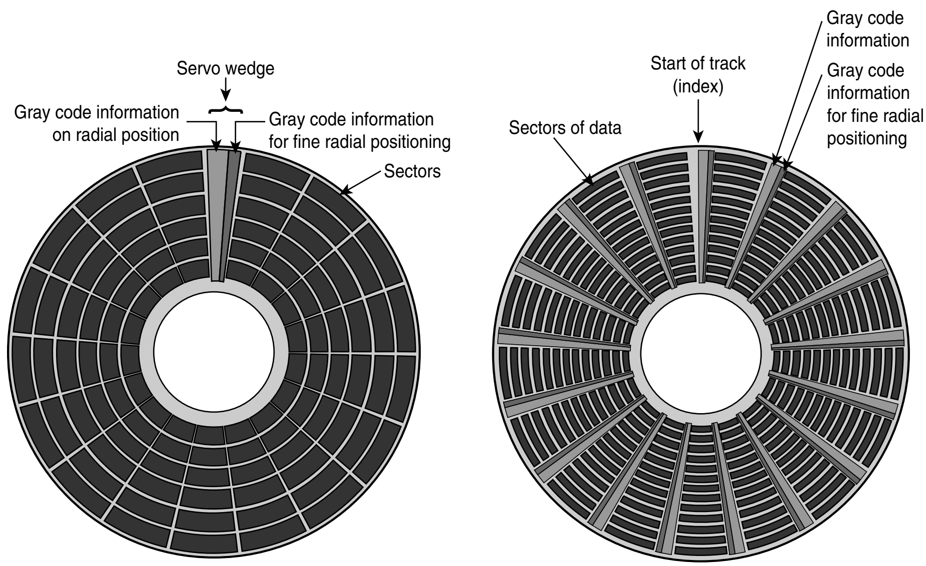

Figure 10.10 A wedge and an embedded servo.

Wedge Servo

Early servo-controlled drives used a technique called a *wedge servo*. In these drives, the gray-code guidance information is contained in a "wedge" slice of the drive in each cylinder immediately preceding the index mark. The index mark indicates the beginning of each track, so the wedge-servo information was written in the PRE-INDEX GAP, which is at the end of each track. This area is provided for speed tolerance and normally is not used by the controller.

Some controllers had to be notified that the drive was using a wedge servo so they could shorten the sector timing to allow for the wedge-servo area. If they were not correctly configured, these controllers would not work properly with the drive.

Another problem was that the servo information appears only one time every revolution, which means that the drive often needed several revolutions before it could accurately determine and adjust the head position. Because of these problems, the wedge servo never was a popular design; it no longer is used in drives.

Embedded Servo

An embedded servo is an enhancement of the wedge servo. Instead of placing the servo code before the beginning of each cylinder, an embedded servo design writes the servo information before the start of each sector. This arrangement enables the positioner circuits to receive feedback many times in a single revolution, making the head positioning much faster and more precise. Another advantage is that every track on the drive has its own positioning information, so each head can quickly and efficiently adjust position to compensate for any changes in the platter or head dimensions, especially for changes due to thermal expansion or physical stress.

Most drives today use an embedded servo to control the positioning system. As in the wedge servo design, the embedded servo information is protected by the drive circuits, and any write operations are blocked whenever the heads are above the servo information. Thus, it is impossible to overwrite the servo information with a low-level format, as some people incorrectly believe.

Although the embedded servo works much better than the wedge servo because the servo feedback information is made available several times in a single disk revolution, a system that offered continuous servo feedback information would be better.

Dedicated Servo

A dedicated servo is a design in which the servo information is written continuously throughout the entire track, rather than just once per track or at the beginning of each sector. Unfortunately, if this procedure were used on the entire drive, no room would be left for data. For this reason, a *dedicated servo* uses one side of one of the platters exclusively for the servo-positioning information. The term "dedicated" comes from the fact that this platter side is completely dedicated to the servo information and cannot contain any data.

When building a dedicated servo drive, the manufacturer deducts one side of one platter from normal read/write usage and records a special set of gray-code data there that indicates the proper track positions. Because the head that rests above this surface cannot be used for normal reading and writing, the gray code can never be erased, and the servo information is protected—as in the other servo designs. No low-level format or other procedure can possibly overwrite the servo information. Figure 10.11 shows a dedicated servo mechanism. Normally, the head on top or one in the center is dedicated for servo use.

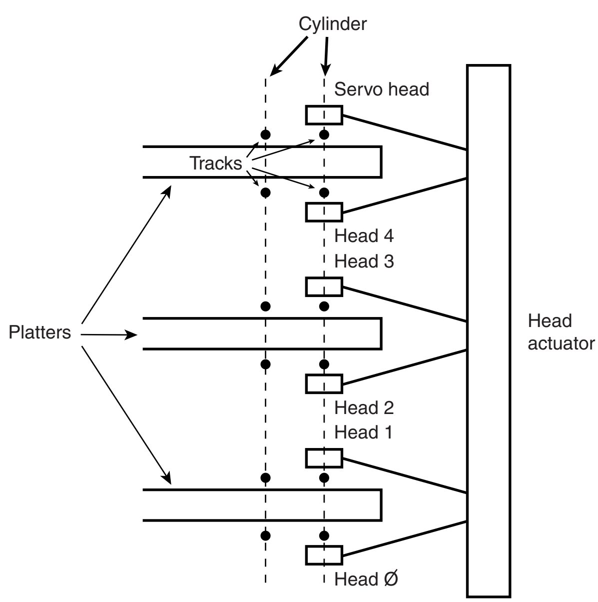

Figure 10.11 A dedicated servo, showing one entire head/side used for servo reading.

When the drive moves the heads to a specific cylinder, the internal drive electronics use the signals received by the servo head to determine the position of the read/write heads. As the heads move, the track counters are read from the dedicated servo surface. When the servo head detects the requested track, the actuator stops. The servo electronics then fine-tune the position so the heads are positioned precisely above the desired cylinder before any writing is permitted. Although only one head is used for servo tracking, the other heads are attached to the same rack so if one head is above the desired cylinder, all the others will be as well.

One way of telling whether a drive uses a dedicated servo platter is if it has an odd number of heads. For example, the Toshiba MK-538FB 1.2GB drive that I used to have in one of my systems had eight platters, but only 15 read/write heads. That drive uses a dedicated servo positioning system, and the 16th head is the servo head. The advantage of the dedicated servo concept is that the servo information is continuously available to the drive, making the head positioning process faster and more precise.

The drawback to a dedicated servo is that dedicating an entire platter surface for servo information is wasteful. Virtually all drives today use a variation on the embedded servo technique instead. Some drives combined a dedicated servo with an embedded servo, but this type of hybrid design is rare. Regardless of whether the servo mechanism is dedicated or embedded, it is far more accurate than the stepper motor mechanisms of the past.

Of course, as mentioned earlier, today's ATA and SCSI drives have head, track, and sector-per-track parameters that are translated from the actual physical numbers. Therefore, you usually can't tell from the published numbers exactly how many heads or platters are contained within a drive.

Automatic Head Parking

When you power off a hard disk drive, the spring tension in each head arm pulls the heads into contact with the platters. The drive is designed to sustain thousands of takeoffs and landings, but it is wise to ensure that the landing occurs at a spot on the platter that contains no data. Older drives required manual head parking; you had to run a program that positioned the drive heads to a landing zone, usually the innermost cylinder, before turning the system off. Modern drives automatically park the heads, so park programs are no longer necessary.

Some amount of abrasion occurs during the landing and takeoff process, removing just a "micro puff" from the magnetic medium—but if the drive is jarred during the landing or takeoff process, real damage can occur.

One benefit of using a voice coil actuator is automatic head parking. In a drive that has a voice coil actuator, the heads are positioned and held by magnetic force. When the power to the drive is removed, the magnetic field that holds the heads stationary over a particular cylinder dissipates, enabling the head rack to skitter across the drive surface and potentially cause damage. In the voice coil design, the head rack is attached to a weak spring at one end and a head stop at the other end. When the system is powered on, the spring is overcome by the magnetic force of the positioner. When the drive is powered off, however, the spring gently drags the head rack to a park-and-lock position before the drive slows down and the heads land. On some drives, you can actually hear the "ting…ting…ting…ting" sound as the heads literally bounce-park themselves, driven by this spring.

On a drive with a voice coil actuator, you activate the parking mechanism by turning off the computer; you do not need to run a program to park or retract the heads. In the event of a power outage, the heads park themselves automatically. (The drives unpark automatically when the system is powered on.)

Air Filters

Nearly all hard disk drives have two air filters. One is called the recirculating filter, and the other is called either a barometric or breather filter. These filters are permanently sealed inside the drive and are designed never to be changed for the life of the drive, unlike many older mainframe hard disks that had changeable filters.

A hard disk on a PC system does not circulate air from inside to outside the HDA or vice versa. The recirculating filter permanently installed inside the HDA is designed to filter only the small particles scraped off the platters during head takeoffs and landings (and possibly any other small particles dislodged inside the drive). Because PC hard disk drives are permanently sealed and do not circulate outside air, they can run in extremely dirty environments (see Figure 10.12).

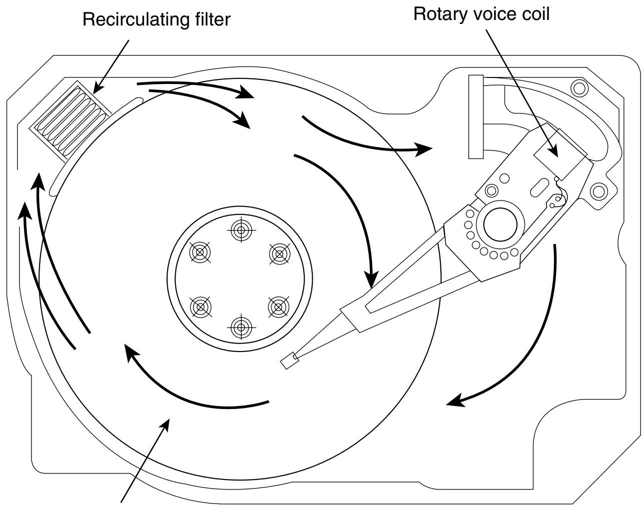

Figure 10.12 Air circulation in a hard disk.

The HDA in a hard disk drive is sealed but not airtight. The HDA is vented through a barometric or breather filter element that enables pressure equalization (breathing) between the inside and outside of the drive. For this reason, most hard drives are rated by the drive's manufacturer to run in a specific range of altitudes, usually from 1,000 feet below to 10,000 feet above sea level. In fact, some hard drives are not rated to exceed 7,000 feet while operating because the air pressure would be too low inside the drive to float the heads properly. As the environmental air pressure changes, air bleeds into or out of the drive so internal and external pressures are identical. Although air does bleed through a vent, contamination usually is not a concern because the barometric filter on this vent is designed to filter out all particles larger than 0.3 microns (about 12 μ-inch) to meet the specifications for cleanliness inside the drive. You can see the vent holes on most drives, which are covered internally by this breather filter. Some drives use even finer grade filter elements to keep out even smaller particles.

I conducted a seminar in Hawaii several years ago, and several of the students were from one of the astronomical observatories atop Mauna Kea. They indicated that virtually all the hard disk drives they had tried to use at the observatory site had failed very quickly, if they worked at all. This was no surprise because the observatories are at the 13,796-foot peak of the mountain, and at that altitude, even people don't function very well! At the time, they had to resort to solid-state (RAM) disks, tape drives, or even floppy disk drives as their primary storage medium. Since then, IBM's Adstar division (which produces all IBM hard drives) has introduced a line of rugged 3 1/2-inch drives that are hermetically sealed (airtight), although they do have air inside the HDA. Because they carry their own internal air under pressure, these drives can operate at any altitude and can also withstand extremes of shock and temperature. The drives are designed for military and industrial applications, such as systems used aboard aircraft and in extremely harsh environments. They are, of course, more expensive than typical hard drives that operate under ambient pressures.

Hard Disk Temperature Acclimation

Because hard drives have a filtered port to bleed air into or out of the HDA, moisture can enter the drive, and after some period of time, it must be assumed that the humidity inside any hard disk is similar to that outside the drive. Humidity can become a serious problem if it is allowed to condense—and especially if you power up the drive while this condensation is present. Most hard disk manufacturers have specified procedures for acclimating a hard drive to a new environment with different temperature and humidity ranges, and especially for bringing a drive into a warmer environment in which condensation can form. This situation should be of special concern to users of laptop or portable systems. If you leave a portable system in an automobile trunk during the winter, for example, it could be catastrophic to bring the machine inside and power it up without allowing it to acclimate to the temperature indoors.

The following text and Table 10.4 are taken from the factory packaging that Control Data Corporation (later Imprimis and eventually Seagate) used to ship with its hard drives:

> If you have just received or removed this unit from a climate with temperatures at or below 50°F (10°C) do not open this container until the following conditions are met, otherwise condensation could occur and damage to the device and/or media may result. Place this package in the operating environment for the time duration according to the temperature chart.

Table 10.4 Hard Disk Drive Environmental Acclimation Table

Previous Climate Temperature	Acclimation Time	Previous Climate Temperature	Acclimation Time
+40°F (+4°C)	13 hours	-10°F (-23°C)	20 hours
+30°F (-1°C)	15 hours	-20°F (-29°C)	22 hours
+20°F (-7°C)	16 hours	-30°F (-34°C) or less	27 hours
+10°F (-12°C)	17 hours		
0°F (-18°C)	18 hours		

As you can see from this table, you must place a hard disk drive that has been stored in a colder-than-normal environment into its normal operating environment for a specified amount of time to allow it to acclimate before you power it on.

Spindle Motors

The motor that spins the platters is called the spindle motor because it is connected to the spindle around which the platters revolve. Spindle motors in hard disk drives are always connected directly; no belts or gears are involved. The motor must be free of noise and vibration; otherwise, it can transmit a rumble to the platters, which can disrupt reading and writing operations.

The spindle motor also must be precisely controlled for speed. The platters in hard disk drives revolve at speeds ranging from 3,600rpm to 15,000rpm (60–250 revolutions per second) or more, and the motor has a control circuit with a feedback loop to monitor and control this speed precisely. Because the speed control must be automatic, hard drives do not have a motor-speed adjustment. Some diagnostics programs claim to measure hard drive rotation speed, but all these programs do is estimate the rotational speed by the timing at which sectors pass under the heads.

There is actually no way for a program to measure the hard disk drive's rotational speed; this measurement can be made only with sophisticated test equipment. Don't be alarmed if some diagnostics program tells you that your drive is spinning at an incorrect speed; most likely, the program is wrong, not the drive. Platter rotation and timing information is not provided through the hard disk controller interface. In the past, software could give approximate rotational speed estimates by performing multiple sector read requests and timing them, but this was valid only when all drives had the same number of sectors per track and spun at the same speed. Zoned-bit recording—combined with the many various rotational speeds used by modern drives, not to mention built-in buffers and caches—means that these calculation estimates cannot be performed accurately by software.

On most drives, the spindle motor is on the bottom of the drive, just below the sealed HDA. Many drives today, however, have the spindle motor built directly into the platter hub inside the HDA. By using an internal hub spindle motor, the manufacturer can stack more platters in the drive because the spindle motor takes up no vertical space.

Note

Spindle motors, particularly on the larger form-factor drives, can consume a great deal of 12-volt power. Most drives require two to three times the normal operating power when the motor first spins the platters. This heavy draw lasts only a few seconds or until the drive platters reach operating speed. If you have more than one drive, you should try to sequence the start of the spindle motors so the power supply does not have to provide such a large load to all the drives at the same time. Most SCSI and some ATA drives have a delayed spindle-motor start feature.

Logic Boards

All hard disk drives have one or more logic boards mounted on them. The logic boards contain the electronics that control the drive's spindle and head actuator systems and present data to the controller in some agreed-upon form. On ATA drives, the boards include the controller itself, whereas SCSI drives include the controller and the SCSI bus adapter circuit.

Many disk drive failures occur in the logic board, not in the mechanical assembly. (This statement does not seem logical, but it is true.) Therefore, you sometimes can repair a failed drive by replacing the logic board rather than the entire drive. Replacing the logic board, moreover, enables you to regain access to the data on the drive—something that replacing the entire drive does not provide.

In many cases, logic boards plug into the drive and are easily replaceable. These boards are usually mounted with standard screw hardware. If a drive is failing and you have a spare, you might be able to verify a logic-board failure by taking the board off the known good drive and mounting it on the bad one. If your suspicions are confirmed, you can order a new logic board from the drive manufacturer, but unless you have data on the drive you need to recover, it might make more sense to buy a new drive, considering today's low disk drive costs.

To reduce costs further, many third-party vendors can also supply replacement logic-board assemblies. These companies often charge much less than the drive manufacturers for the same components. (See the Vendor List on the CD for vendors of drive components, including logic boards.)

Cables and Connectors

Hard disk drives typically have several connectors for interfacing to the computer, receiving power, and sometimes grounding to the system chassis. Most drives have at least these three types of connectors:

- Interface connector(s)
- Power connector
- Optional ground connector (tab)

Of these, the interface connectors are the most important because they carry the data and command signals between the system and the drive. In most cases, the drive interface cables can be connected in a daisy-chain or bus-type configuration. Most interfaces support at least two devices, and SCSI (Small Computer System Interface) can support up to seven (Wide SCSI can support up to 15) devices in the chain, in addition to the host adapter. Older interfaces, such as ST-506/412 or ESDI (Enhanced Small Device Interface), used separate cables for data and control signals, but today's SCSI and ATA (AT Attachment) drives have a single connector.

◀◀ See "ATA I/O Connector," p. 486, and "SCSI Cables and Connectors," p. 526.

The power connector is usually the same four-pin type that is used in floppy disk drives, and the same power-supply connector plugs into it. Most hard disk drives use both 5- and 12-volt power, although some of the smaller drives designed for portable applications use only 5-volt power. In most cases, the 12-volt power runs the spindle motor and head actuator, and the 5-volt power runs the circuitry. Make sure your power supply can supply adequate power for the hard disk drives installed in your system.

The 12-volt power consumption of a drive usually varies with the physical size of the unit. The larger the drive is, the faster it spins. In addition, the more platters there are to spin, the more power it requires. For example, most of the 3 1/2-inch drives on the market today use roughly one-half to one-fourth the power (in watts) of the older 5 1/4-inch drives. Some of the very small (2 1/2- or 1.8-inch) hard disks barely sip electrical power and actually use 1 watt or less!

A grounding tab provides an optional ground connection between the drive and the system's chassis. In most computers, the hard disk drive is mounted directly to the chassis using screws, or the drive is grounded via the ground wires in the power connector, so an extra ground wire is unnecessary.

Configuration Items

To configure a hard disk drive for installation in a system, you usually must set several jumpers (and, possibly, terminating resistors) properly. These items vary from interface to interface and often from drive to drive, as well.

The Faceplate or Bezel

Many hard disk drives offer as an option a front faceplate, or bezel (see Figure 10.13). A bezel usually is supplied as an option for the drive rather than as a standard item. In most cases today, the bezel is a part of the case and not the drive itself.

Older systems had the drive installed so it was visible outside the system case. To cover the hole in the case, you would use an optional bezel or faceplate. Bezels often come in several sizes and colors to match various PC systems. Many faceplate configurations for 3 1/2-inch drives are available, including bezels that fit 3 1/2-inch drive bays as well as 5 1/4-inch drive bays. You even have a choice of colors (usually black, cream, or white).

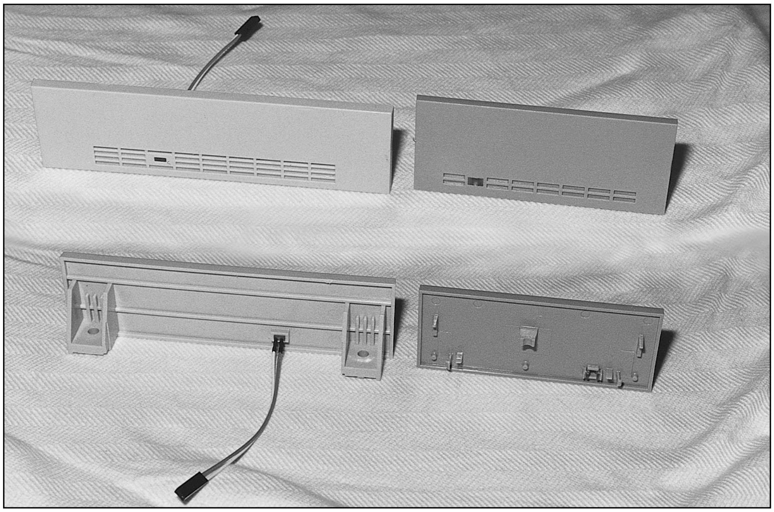

Figure 10.13 Typical 5 1/4- and 3 1/2-inch hard drives bezel shown from the front (as seen on the outside of the PC case) (top) and from the back (bottom—the inside mounting and LED wiring).

Some bezels feature a light-emitting diode (LED) that flickers when your hard disk is in use. The LED is mounted in the bezel; the wire hanging off the back of the LED plugs into the drive. In some drives, the LED is permanently mounted on the drive, and the bezel has a clear or colored window so you can see the LED flicker while the drive is being accessed.

In systems in which the hard disk is hidden by the unit's cover, a bezel is not needed. In fact, using a bezel can prevent the cover from resting on the chassis properly, in which case the bezel will have to be removed. If you are installing a drive that does not have a proper bezel, frame, or rails to attach to the system, check the Vendor List on the CD; several listed vendors offer these accessories for a variety of drives.

Hard Disk Features

To make the best decision in purchasing a hard disk for your system or to understand what distinguishes one brand of hard disk from another, you must consider many features. This section examines some of the issues you should consider when you evaluate drives:

- Reliability
- Performance
- Cost

Reliability

When you shop for a drive, you might notice a statistic called the Mean Time Between Failures (MTBF) described in the drive specifications. MTBF figures usually range from 300,000 to 1,000,000 hours or more. I usually ignore these figures because they are derived theoretically.

In understanding the MTBF claims, you must understand how the manufacturers arrive at them and what they mean. Most manufacturers have a long history of building drives, and their drives have seen millions of hours of cumulative use. They can look at the failure rate for previous drive models with the same components and calculate a failure rate for a new drive based on the components used to build the drive assembly. For the electronic circuit board, they also can use industry standard techniques for predicting the failure of the integrated electronics. This enables them to calculate the predicted failure rate for the entire drive unit.

To understand what these numbers mean, you must know that the MTBF claims apply to a population of drives, not an individual drive. This means that if a drive claims to have an MTBF of 500,000 hours, you can expect a failure in that population of drives in 500,000 hours of total running time. If 1,000,000 drives of this model are in service and all 1,000,000 are running at once, you can expect one failure out of this entire population every half-hour. MTBF statistics are not useful for predicting the failure of any individual drive or a small sample of drives.

You also need to understand the meaning of the word *failure*. In this sense, a failure is a fault that requires the drive to be returned to the manufacturer for repair, not an occasional failure to read or write a file correctly.

Finally, as some drive manufacturers point out, this measure of MTBF should really be called mean time to first failure. "Between failures" implies that the drive fails, is returned for repair, and then at some point fails again. The interval between repair and the second failure here would be the MTBF. Because in most cases, a failed hard drive that would need manufacturer repair is replaced rather than repaired, the whole MTBF concept is misnamed.

The bottom line is that I do not really place much emphasis on MTBF figures. For an individual drive, they are not accurate predictors of reliability. However, if you are an information systems manager considering the purchase of thousands of PCs or drives per year, or a system vendor building and supporting thousands of systems, it is worth your while to examine these numbers and study the methods used to calculate them by each vendor. If you can understand the vendor's calculations and compare the actual reliability of a large sample of drives, you can purchase more reliable drives and save time and money in service and support.

S.M.A.R.T.

S.M.A.R.T. (Self-Monitoring, Analysis, and Reporting Technology) is an industry standard providing failure prediction for disk drives. When S.M.A.R.T. is enabled for a given drive, the drive monitors predetermined attributes that are susceptible to or indicative of drive degradation. Based on changes in the monitored attributes, a failure prediction can be made. If a failure is deemed likely to occur, S.M.A.R.T. makes a status report available so the system BIOS or driver software can notify the user of the impending problems, perhaps enabling the user to back up the data on the drive before any real problems occur.

Predictable failures are the types of failures S.M.A.R.T. attempts to detect. These failures result from the gradual degradation of the drive's performance. According to Seagate, 60% of drive failures are mechanical, which is exactly the type of failures S.M.A.R.T. is designed to predict.

Of course, not all failures are predictable, and S.M.A.R.T. cannot help with unpredictable failures that occur without any advance warning. These can be caused by static electricity; improper handling or sudden shock; or circuit failure, such as thermal-related solder problems or component failure.

S.M.A.R.T. was originally created by IBM in 1992. That year IBM began shipping 3 1/2-inch hard disk drives equipped with Predictive Failure Analysis (PFA), an IBM-developed technology that periodically measures selected drive attributes and sends a warning message when a predefined threshold is exceeded. IBM turned this technology over to the ANSI organization, and it subsequently became the ANSI-standard S.M.A.R.T. protocol for SCSI drives, as defined in the ANSI-SCSI Informational Exception Control (IEC) document X3T10/94-190.

Interest in extending this technology to IDE/ATA drives led to the creation of the S.M.A.R.T. Working Group in 1995. Besides IBM, other companies represented in the original group were Seagate Technology, Conner Peripherals (now a part of Seagate), Fujitsu, Hewlett-Packard, Maxtor, Quantum, and Western Digital. The S.M.A.R.T. specification produced by this group and placed in the public domain covers both IDE/ATA and SCSI hard disk drives and can be found in most of the more recently produced drives on the market.

The S.M.A.R.T. design of attributes and thresholds is similar in IDE/ATA and SCSI environments, but the reporting of information differs.

In an IDE/ATA environment, driver software on the system interprets the alarm signal from the drive generated by the S.M.A.R.T. "report status" command. The driver polls the drive on a regular basis to check the status of this command and, if it signals imminent failure, sends an alarm to the operating system where it will be passed on via an error message to the end user. This structure also enables future enhancements, which might allow reporting of information other than drive failure conditions. The system can read and evaluate the attributes and alarms reported in addition to the basic "report status" command.

SCSI drives with S.M.A.R.T. communicate a reliability condition only as either good or failing. In a SCSI environment, the failure decision occurs at the disk drive, and the host notifies the user for action. The SCSI specification provides for a sense bit to be flagged if the drive determines that a reliability issue exists. The system then alerts the end user via a message.

The basic requirements for S.M.A.R.T. to function in a system are simple. All you need are a S.M.A.R.T.-capable hard disk drive and a S.M.A.R.T.-aware BIOS or hard disk driver for your particular operating system. If your BIOS does not support S.M.A.R.T., utility programs are available that can support S.M.A.R.T. on a given system. These include Norton Disk Doctor from Symantec, EZ Drive from StorageSoft, and Data Advisor from Ontrack Data International.

Note that traditional disk diagnostics, such as Scandisk and Norton Disk Doctor, work only on the data sectors of the disk surface and do not monitor all the drive functions that are monitored by S.M.A.R.T. Most modern disk drives keep spare sectors available to use as substitutes for sectors that have errors. When one of these spares is reallocated, the drive reports the activity to the S.M.A.R.T. counter but still looks completely defect-free to a surface analysis utility, such as Scandisk.

Drives with S.M.A.R.T. monitor a variety of attributes that vary from one manufacturer to another. Attributes are selected by the device manufacturer based on their capability to contribute to the prediction of degrading or fault conditions for that particular drive. Most drive manufacturers consider the specific set of attributes being used and the identity of those attributes as vendor specific and proprietary.

Some drives monitor the floating height of the head above the magnetic media. If this height changes from a nominal figure, the drive could fail. Other drives can monitor different attributes, such as ECC (error correcting code) circuitry that indicates whether soft errors are occurring when reading or writing data. Some of the attributes monitored on various drives include the following:

- Head floating height
- Data throughput performance
- Spin-up time
- Reallocated (spared) sector count
- Seek error rate
- Seek time performance

- Drive spin-up retry count
- Drive calibration retry count

Each attribute has a threshold limit that is used to determine the existence of a degrading or fault condition. These thresholds are set by the drive manufacturer and cannot be changed.

When sufficient changes occur in the monitored attributes to trigger a S.M.A.R.T. alert, the drive sends an alert message via an IDE/ATA or a SCSI command (depending on the type of hard disk drive you have) to the hard disk driver in the system BIOS, which then forwards the message to the operating system. The operating system then displays a warning message as follows:

> Immediately back up your data and replace your hard disk drive. A failure may be imminent.

The message might contain additional information, such as which physical device initiated the alert; a list of the logical drives (partitions) that correspond to the physical device; and even the type, manufacturer, and serial number of the device.

The first thing to do when you receive such an alert is to heed the warning and back up all the data on the drive. It also is wise to back up to new media and not overwrite any previous good backups you might have, just in case the drive fails before the backup is complete.

After backing up your data, what should you do? S.M.A.R.T. warnings can be caused by an external source and might not actually indicate that the drive itself is going to fail. For example, environmental changes, such as high or low ambient temperatures, can trigger a S.M.A.R.T. alert, as can excessive vibration in the drive caused by an external source. Additionally, electrical interference from motors or other devices on the same circuit as your PC can induce these alerts.

If the alert was not caused by an external source, a drive replacement might be indicated. If the drive is under warranty, contact the vendor and ask them whether they will replace it. If no further alerts occur, the problem might have been an anomaly, and you might not need to replace the drive. If you receive further alerts, replacing the drive is recommended. If you can connect both the new and existing (failing) drive to the same system, you might be able to copy the entire contents of the existing drive to the new one, saving you from having to install or reload all the applications and data from your backup.

Performance

When you select a hard disk drive, one of the important features you should consider is the performance (speed) of the drive. Hard drives can have a wide range of performance capabilities. As is true of many things, one of the best indicators of a drive's relative performance is its price. An old saying from the automobile-racing industry is appropriate here: "Speed costs money. How fast do you want to go?"

You can measure the speed of a disk drive in two ways:

- Average seek time
- Transfer rate

Average seek time, normally measured in milliseconds (ms), is the average amount of time it takes to move the heads from one cylinder to another a random distance away. One way to measure this specification is to run many random track-seek operations and then divide the timed results by the number of seeks performed. This method provides an average time for a single seek.

The standard method used by many drive manufacturers to measure the average seek time involves measuring the time it takes the heads to move across one-third of the total cylinders. Average seek time depends only on the drive itself; the type of interface or controller has little effect on this specification. The rating is a gauge of the capabilities of the head actuator.

Note

Be wary of benchmarks that claim to measure drive seek performance. Most ATA/IDE and SCSI drives use a scheme called sector translation, so any commands the drive receives to move the heads to a specific cylinder might not actually result in the intended physical movement. This situation renders some benchmarks meaningless for those types of drives. SCSI drives also require an additional step because the commands first must be sent to the drive over the SCSI bus. These drives might seem to have the fastest access times because the command overhead is not factored in by most benchmarks. However, when this overhead is factored in by benchmark programs, these drives receive poor performance figures.

Average Access Time

A slightly different measurement, called average access time, involves another element called *latency*. Latency is the average time (in milliseconds) it takes for a sector to be available after the heads have reached a track. On average, this figure is half the time it takes for the disk to rotate once. A drive that spins twice as fast would have half the latency. A measurement of a drive's average access time is the sum of its average seek time and latency. This number provides the average amount of time required before the drive can access a randomly requested sector.

Latency

Latency is a factor in disk read and write performance. Decreasing the latency increases the speed of access to data or files and is accomplished only by spinning the drive platters more quickly. Latency figures for most popular drive rotational speeds are shown in Table 10.5.

Table 10.5 Hard Disk Rotation Speeds and Their Latencies

Revs/Minute	Revs/Second	Latency
3,600	60	8.33
4,200	70	7.14
5,400	90	5.56
7,200	120	4.17
10,000	167	3.00
15,000	250	2.00

Many drives today spin at 7,200rpm, resulting in a latency time of only 4.17ms, whereas others spin at 10,000rpm or even 15,000rpm, resulting in incredible 3.00ms or 2.00ms latency figures. In addition to increasing performance where real-world access to data is concerned, spinning the platters more quickly also increases the data-transfer rate after the heads arrive at the desired sectors.

Transfer Rate

The transfer rate is probably more important to overall system performance than any other statistic, but it is also one of the most misunderstood specifications. The problem stems from the fact that now several transfer rates can be specified for a given drive.

Most drive manufacturers now report up to five transfer rates. One is the interface transfer rate, which for most newer ATA drives is 100MB/sec. The other (FAR more important) transfer rate specifications are the media transfer rates, which can be expressed as a raw maximum, a raw minimum, a formatted maximum, or a formatted minimum. Few report the average, but that can be easily calculated.

The media transfer rate is far more important than the interface transfer rate because the media transfer rate is the true rate at which data can be read from the disk, which is how fast data can be read from the drive platters (media). It is the maximum rate that any sustained transfer can hope to achieve.

Drive makers report a minimum and maximum media transfer rate because drives today have a zoned recording with various numbers of sectors per track. Typically, a drive is divided into 16 zones, and the inner zone has about half the sectors (and therefore about half the transfer rate) of the outer zone. Because the drive spins at a constant rate, data is read more quickly from the outer cylinders (with more sectors per track) than from the inner cylinders.

Another issue is the raw transfer rate versus the formatted transfer rate. The *raw* rate refers to how fast bits can be read off the media. Because not all bits represent data (some are intersector or ID bits), and because some time is lost when the heads have to move from track to track, the *formatted* transfer rate represents the true rate at which data can be read from or written to the drive.

Note that some manufacturers report only raw transfer rates, but you usually can figure that the formatted rates are about two-thirds of the raw rates. Likewise, some manufacturers report only maximum transfer rates (either raw, formatted, or both); in that case you can generally assume the minimum transfer rate is one-half of the maximum and that the average transfer rate is three-fourths of the maximum.

Let's look at a specific drive as an example. The IBM Deskstar 60GXP is one of the fastest ATA/IDE drives on the market, spins at 7,200rpm, and fully supports the ATA/100 interface transfer rate (100MB/sec from the controller to the motherboard). As with all current drives, the actual transfer rate is much less.

Table 10.6 shows the specifications for the 7,200rpm Ultra-ATA/100 IBM Deskstar 60GXP drive.

Table 10.6 Transfer Rate Specifications for the IBM Deskstar 60GXP Drive

Transfer Rates	Megabits/Sec	Megabytes/Sec
Interface Transfer Rate	800Mb/sec	100.0MB/sec
Raw Media Transfer Rate (Min)	253Mb/sec	31.6MB/sec
Raw Media Transfer Rate (Max)	494Mb/sec	61.8MB/sec
Formatted Media Transfer Rate (Min)	167Mb/sec	20.9MB/sec
Formatted Media Transfer Rate (Max)	326Mb/sec	40.8MB/sec
Formatted Media Transfer Rate (Avg)	247Mb/sec	30.8MB/sec

MB/sec = Million bytes per second; Mb/sec = Million bits per second

As you can see, the TRUE media transfer rate for this drive is between 20.9MB/sec and 40.8MB/sec, or an average of about 30.8MB/sec, or less than one-third of the interface transfer rate. Of course, if this were your drive you shouldn't be dissapointed becuase 30.8MB/sec is excellent performance—in fact, this is one of the fastest ATA drives on the market. Many, if not most other, ATA/IDE drives would have equal or slower performance.

A common question I get is about upgrading the ATA interface in a system. Many people are using older motherboards that support only ATA/33 or ATA/66 modes and not the faster ATA/100 specification. After studying the true formatted media transfer rates of most drives, you can see why I generally do not recommend installing a separate ATA/100 controller for those systems. Those who perform such an upgrade will see little if any increase in performance. This is because in almost all cases, the drives they are using will be on average slower than even ATA/33—and often significantly slower than the ATA/66 or ATA/100 interface speeds.

Two primary factors contribute to transfer rate performance: rotational speed and the linear recording density or sector-per-track figures. When comparing two drives with the same number of sectors per track, the drive that spins more quickly will transfer data more quickly. Likewise, when comparing two drives with identical rotational speeds, the drive with the higher recording density (more sectors per track) will be faster. A higher-density drive can be faster than one that spins faster—both factors have to be taken into account.

Let's look at another example. One of the fastest rotating drives today is the Seagate Cheetah X15, which spins at 15,000rpm.

Table 10.7 shows the specifications for the 15,000rpm Ultra3-SCSI/160 Seagate Cheetah X15 drive.

Table 10.7 Transfer Rate Specifications for the Seagate Cheetah X15 Drive

Transfer Rates	Megabits/Sec	Megabytes/Sec
Interface Transfer Rate	1,280Mb/sec	160.0MB/sec
Raw Media Transfer Rate (Min)	385Mb/sec	48.1MB/sec
Raw Media Transfer Rate (Max)	508Mb/sec	63.5MB/sec
Formatted Media Transfer Rate (Min)	299Mb/sec	37.4MB/sec
Formatted Media Transfer Rate (Max)	391Mb/sec	48.9MB/sec
Formatted Media Transfer Rate (Avg)	345Mb/sec	43.2MB/sec

As a comparison, Table 10.8 contains the specifications for the 10,000rpm Ultra3-SCSI/160 Seagate Cheetah 73LP drive.

Table 10.8 Transfer Rates for the Seagate Cheetah 73LP Drive

Transfer Rates	Megabits/Sec	Megabytes/Sec
Interface Transfer Rate	1,280Mb/sec	160.0MB/sec
Raw Media Transfer Rate (Min)	399Mb/sec	49.9MB/sec
Raw Media Transfer Rate (Max)	671Mb/sec	83.9MB/sec
Formatted Media Transfer Rate (Min)	307Mb/sec	38.4MB/sec
Formatted Media Transfer Rate (Max)	511Mb/sec	63.9MB/sec
Formatted Media Transfer Rate (Avg)	409Mb/sec	51.2MB/sec

As you can see, in this case the 10,000rpm Cheetah 73LP is significantly faster than the 15,000rpm Cheetah X15. Neither of these drives, however, is close to the Ultra3 SCSI (160MB/sec) bandwidth that the interface would allow. With a comparison such as this, you can see that you need to be careful. Don't just compare one specification, such as rotational speed, because in some cases (like this one), the drive that spins twice as quickly is actually slower in transfer performance. This is a good reminder why you need to be careful with simplistic comparisons. With hard drives, the bottom line is that the media transfer rate is probably the most important specification you can know about a drive, and faster is better.

With older drives the manufacturers often reported minimum and maximum sector per track specifications, which—combined with the rotational speed—can be used to calculate true formatted media performance. Also, be aware that many drives (especially zoned-bit recording drives) are configured with sector translation, so the number of sectors per track reported by the BIOS has little to do with the actual physical characteristics of the drive. You must know the drive's true physical parameters, rather than the values the BIOS uses.

When you know these figures, you can use the following formula to determine the true media data transfer rate in millions of bytes per second (MBps):

Media Transfer Rate (MBps) = SPT×512 bytes×rpm/60 seconds/1,000,000 bytes

For example, the IBM Travelstar 32GH 32GB 2 1/2-inch drive spins at 5,411rpm and has an average of 472 sectors per track. The average media transfer rate for this drive is figured as follows:

472×512×(5,411/60)/1,000,000 = 21.8MBps

Using this formula, you can calculate the media transfer rate of any drive, if you know the rotational speed and average sectors per track.

Some drives report their transfer speeds as a maximum sustainable formatted rate. For example, the IBM Deskstar 60GXP drive detailed earlier has minimum and maximum formatted transfer rates of 20.9MB/sec and 40.8MB/sec, respectively (to or from the media), and spins at 7,200rpm, which works out to be:

20.9×1,000,000/(7200/60)/512 = 340 sectors per track maximum

40.8×1,000,000/(7200/60)/512 = 664 sectors per track maximum

Averaging these figures results in a 30.8MB/sec average transfer rate and 502 sectors per track average.

Note that these are the true numbers of sectors per track (with differing values across 18 zones in this case) even though the drive would report only 63 sectors per track if queried with the ATA Identify command, such as in a BIOS Setup with autodetect. Don't be confused because the numbers reported by the drive are different from what is actually inside. For example, this drive has 6 actual heads even though it would report 16, and it has about 34,000 actual cylinders even though it would report 16,384 to the BIOS setup.

Cache Programs and Caching Controllers

At the software level, disk cache programs, such as SMARTDRV (in DOS) and VCACHE (in Windows 9x, Windows NT, and Windows 2000), can have a major effect on disk drive performance. These cache programs hook into the BIOS hard drive interrupt and intercept the read and write calls to the disk BIOS from application programs and device drivers.

When an application program wants to read data from a hard drive, the cache program intercepts the read request, passes the read request to the hard drive controller in the usual way, saves the data read from the disk in its cache memory buffer, and then passes the data back to the application program. Depending on the size of the cache buffer, data from numerous sectors can be read into and saved in the buffer.

When the application wants to read more data, the cache program again intercepts the request and examines its buffers to see whether the requested data is still in the cache. If so, the program passes the data back from the cache to the application immediately, without another hard drive operation. Because the cached data is stored in memory, this method speeds access tremendously and can greatly affect disk drive performance measurements.

Most controllers now have some form of built-in hardware buffer or cache that doesn't intercept or use any BIOS interrupts. Instead, the drive caches data at the hardware level, which is invisible to normal performance-measurement software. Manufacturers originally included track read-ahead buffers in controllers to permit 1:1 interleave performance. Some manufacturers now increase the size of these read-ahead buffers in the controller, whereas others add intelligence by using a cache instead of a simple buffer.

Many ATA and SCSI drives have cache memory built directly into the drive's onboard controller. Most newer ATA drives have between 512KB and 2MB of built-in cache, whereas many SCSI drives have up to 16MB. I remember when 640KB was a lot of memory for an entire system. Now, tiny 3 1/2-inch hard disk drives can have 16MB built right in! These integrated caches are part of the reason many ATA (IDE) and SCSI drives perform so well.

Although software and hardware caches can make a drive faster for routine transfer operations, a cache will not affect the true maximum transfer rate the drive can sustain.

Interleave Selection

In a discussion of disk performance, the issue of interleave often comes up. Although traditionally this was more a controller performance issue than a drive issue, modern ATA/IDE and SCSI hard disk drives with built-in controllers are fully capable of processing the data as fast as the drive can send it. In other words, all modern ATA and SCSI drives are formatted with no interleave (sometimes expressed as a 1:1 interleave ratio). On older hard drive types, such as MFM and ESDI, you could modify the interleave during a low-level format to optimize the drive's performance. Today, drives are low-level formatted at the factory and interleave adjustments are a moot topic.

Note

For more information on interleaving and cylinder skewing as used on older drives, see Chapter 10 of *Upgrading and Repairing PCs, 12th Edition*, included in its entirety on the CD included with this book.

Cost

The cost of hard disk storage is continually falling. You can now purchase a 30GB ATA drive for around $150, which is about half a cent per megabyte.

A drive I bought in 1983 had a maximum capacity of 10MB and cost $1,800. At current pricing (0.5 cents per megabyte), that drive is worth about 5 cents!

Of course, the cost of drives continues to fall, and eventually, even half a cent per megabyte will seem expensive. Because of the low costs of disk storage today, not many 3-1/2 inch drives with capacities of less than 10GB are even being manufactured.

Capacity

Four figures are commonly used in advertising drive capacity:

- Unformatted capacity, in millions of bytes
- Formatted capacity, in millions of bytes
- Unformatted capacity, in megabytes
- Formatted capacity, in megabytes

The term *formatted*, in these figures, refers to the low-level (or physical) formatting of the drive. Most manufacturers of ATA/IDE and SCSI drives now report only the formatted capacities because these drives are delivered preformatted. Usually, advertisements and specifications refer to the unformatted or formatted capacity in millions of bytes because these figures are larger than the same capacity expressed in megabytes. This situation generates a great deal of confusion when the user runs FDISK (which reports total drive capacity in megabytes) and wonders where the missing space is. This question can seem troubling. Fortunately, the answer is easy; it only involves a little math to figure it out.

Perhaps the most common questions I get are concerning "missing" drive capacity. Consider the following example: I just installed a new Seagate ST330630A drive in a system, which is advertised as having 30.6GB capacity. After entering the drive parameters in the BIOS Setup (I used the autodetect feature to automate the process), when I went to partition the drive using FDISK, the capacity was reported by FDISK as only 203MB! "What happened to the other 29.8GB?"

The answer is only a few calculations away. By multiplying the drive specification parameters, you get this result:

Total sectors:	59,777,640
Bytes per sector:	512
Total bytes (in decimal megabytes):	30,606
Total bytes (in decimal gigabytes):	30.6
Total bytes (in binary megabytes):	29,188
Total bytes (in binary gigabytes):	28.5
As reported by FDISK:	29,188

All the numbers in the table above are correct. Drive manufacturers usually report drive capacity in decimal megabytes (millions of bytes) because they result in larger, more impressive sounding numbers, although your BIOS and especially the FDISK drive partitioning software report the capacity in binary megabytes. One decimal megabyte equals one million bytes, whereas one binary megabyte equals 1,048,576 bytes (or 1,024KB, in which each kilobyte is 1,024 bytes). So the bottom line is that, because the same abbreviations are often used for both millions of bytes and megabytes, this 30.6GB drive could also be called a 28.5GB drive, depending on how you look at it!

Specific Recommendations

If you are going to add a hard disk to a system today, I can give you a few recommendations. For the drive interface, there really are only two types to consider:

- ATA (AT Attachment, also called IDE)
- SCSI (Small Computer System Interface)

These interfaces are covered more completely in Chapters 7, "The IDE Interface," and 8, "The SCSI Interface." SCSI offers great expandability, cross-platform compatibility, high capacity, performance, and flexibility. ATA is less expensive than SCSI and also offers a very high-performance solution, but expansion, compatibility, capacity, and flexibility are more limited when compared with SCSI. I usually recommend ATA for most people for two reasons. First, the interface is already integrated into virtually every motherboard and BIOS sold today. Second, most users will not need more capacity than the four devices supported by the standard primary and secondary ATA interfaces found in most systems. SCSI offers additional performance potential with a multithreaded operating system, such as Windows NT/2000, as well as support for more devices, but it also requires the purchase of a separate host adapter card, which is in addition to the higher cost for the drive itself.

Note

Note that the current fastest ATA standard is UltraDMA/100 or UltraATA/100, which runs at 100MB/sec raw interface transfer rate. Serial ATA is coming out with a 150MB/sec transfer rate. The current fastest SCSI standard is Ultra4 (also called Ultra/320)-SCSI, which runs a raw interface transfer rate of 320MB/sec. Both interfaces have improvements slated that should double their respective transfer rates in the future.

CHAPTER 11

Floppy Disk Storage

This chapter examines the standard types of floppy disk drives and disks that have been used in PCs since the beginning. It explores the various types of drives and disks, how they function, and how to properly install and service them. The newer high-capacity floppy drives, such as the SuperDisk (LS-120), are covered separately in Chapter 12, "High-Capacity Removable Storage." Magnetic storage in general—that is, how data is actually stored on the disk media—is covered in Chapter 9, "Magnetic Storage Principles."

Floppy Disk Drives

Although no longer used for primary storage, the floppy is still necessary in most systems as a system installation and configuration device, and also especially when troubleshooting. When building up a system or installing one from scratch, the floppy is often used to load software necessary for partitioning and formatting the hard disk, as well as to run diagnostics in case of problems.

Another interesting use is in the transfer of data from some digital cameras. A device called the *FlashPath adapter* enables your PC to read SmartMedia flash memory storage chips via the floppy drive. These are covered in more detail in Chapter 12, although I think they are worth mentioning here.

Even though higher-capacity storage devices are available and most modern systems can boot directly from CD-ROMs, the ubiquitous floppy drive will likely remain as a staple in systems for several more years to come.

History of the Floppy

Alan Shugart is generally credited with inventing the floppy disk drive in 1967 while working for IBM. One of Shugart's senior engineers, David Noble, actually proposed the flexible medium (then 8 inches in diameter) and the protective jacket with the fabric lining. Shugart left IBM in 1969, and in 1976 his company, Shugart Associates, introduced the minifloppy (5 1/4-inch) disk drive. It, of course, became the standard eventually used by personal computers, rapidly replacing the 8-inch drives. He also helped create the Shugart Associates System Interface (SASI), which was later renamed SCSI (small computer system interface) when approved as an ANSI standard.

Sony introduced the first 3 1/2-inch microfloppy drives and disks in 1983. The first significant company to adopt the 3 1/2-inch floppy for general use was Hewlett-Packard in 1984 with its partially PC-compatible HP-150 system. The industry adoption of the 3 1/2-inch drive was furthered when Apple used it in the first Macintosh systems in 1984, and IBM put the drive into its entire PC product line starting in 1986.

Note that all PC floppy disk drives are still based on (and mostly compatible with) the original Shugart designs, including the electrical and command interfaces. Compared to other parts of the PC, the floppy disk drive has undergone relatively few changes over the years.

Drive Components

All floppy disk drives, regardless of type, consist of several basic common components. To properly install and service a disk drive, you must be able to identify these components and understand their functions (see Figure 11.1).

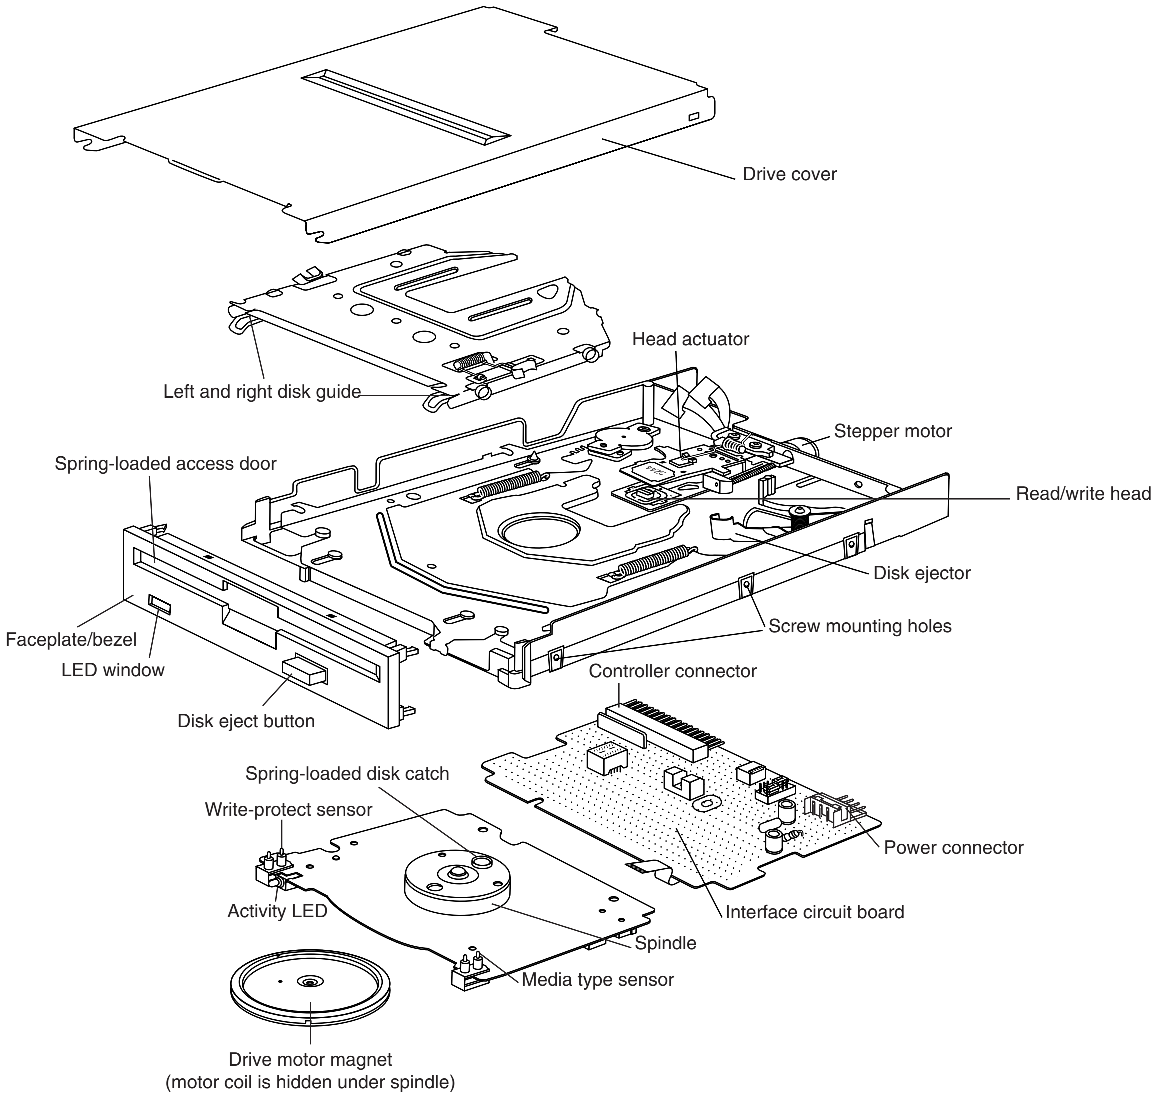

Figure 11.1 A typical floppy disk drive.

Read/Write Heads

A floppy disk drive normally has two read/write heads, one for each side of the disk, with both heads being used for reading and writing on their respective disk sides (see Figure 11.2). At one time, single-sided drives were available for PC systems (the original PC had such drives), but today single-sided drives are a fading memory.

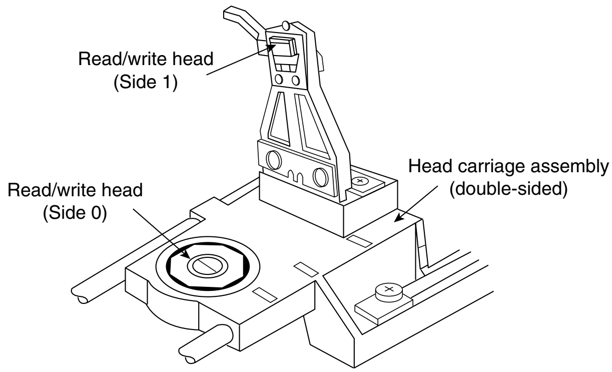

Figure 11.2 A double-sided drive head assembly.

Note

Many people do not realize that Head 0, or the first head on a floppy disk drive, is the bottom one. Single-sided drives, in fact, used only the bottom head; the top head has been replaced by a felt pressure pad. Another bit of disk trivia is that the top head (Head 1) is not positioned directly over the bottom head (Head 0). The top head is instead offset by either four or eight tracks inward from the bottom head, depending on the drive type.

The head mechanism is moved by a motor called a *head actuator*. The heads can move in and out over the surface of the disk in a straight line to position themselves over various tracks. On a floppy drive, the heads move in and out tangentially to the tracks they record on the disk. This is different from hard disks, where the heads move on a rotating arm similar to the tone-arm of a record player. Because the top and bottom heads are mounted on the same rack, or mechanism, they move in unison and cannot move independently of each other. The upper and lower heads each define tracks on their respective sides of the disk medium, whereas at any given head position, the tracks under the top and bottom head simultaneously are called a *cylinder*. Most floppy disks are recorded with 80 tracks on each side (160 tracks total), which is 80 cylinders.

The heads themselves are made of soft ferrous (iron) compounds with electromagnetic coils. Each head is a composite design, with a read/write head centered within two tunnel-erase heads in the same physical assembly (see Figure 11.3).

Floppy disk drives use a recording method called *tunnel erasure*. As the drive writes to a track, the trailing tunnel-erase heads erase the outer bands of the track, trimming it cleanly on the disk. The heads force the data into a specified narrow "tunnel" on each track. This process prevents the signal from one track from being confused with the signals from adjacent tracks, which would happen if the signal were allowed to naturally "taper off" to each side. *Alignment* is the placement of the heads with respect to the tracks they must read and write. Head alignment can be checked against only some sort of reference-standard disk recorded by a perfectly aligned machine. These types of disks are available, and you can use one to check your drive's alignment. However, this is usually not practical for the end user because one calibrated analog alignment disk can cost more than a new drive.

The floppy disk drive's two heads are spring-loaded and physically grip the disk with a small amount of pressure, which means they are in direct contact with the disk surface while reading and writing to the disk. Because floppy disk drives spin at only 300rpm or 360rpm, this pressure does not present an excessive friction problem. Some newer disks are specially coated with Teflon or other compounds to further reduce friction and enable the disk to slide more easily under the heads. Because of the contact between the heads and disk, a buildup of the magnetic material from the disk eventually forms on the heads. The buildup should periodically be cleaned off the heads as part of a preventive maintenance or normal service program. Most manufacturers recommend cleaning the heads after every 40 hours of drive operation, which, considering how many people use these drives today, could be a lifetime.

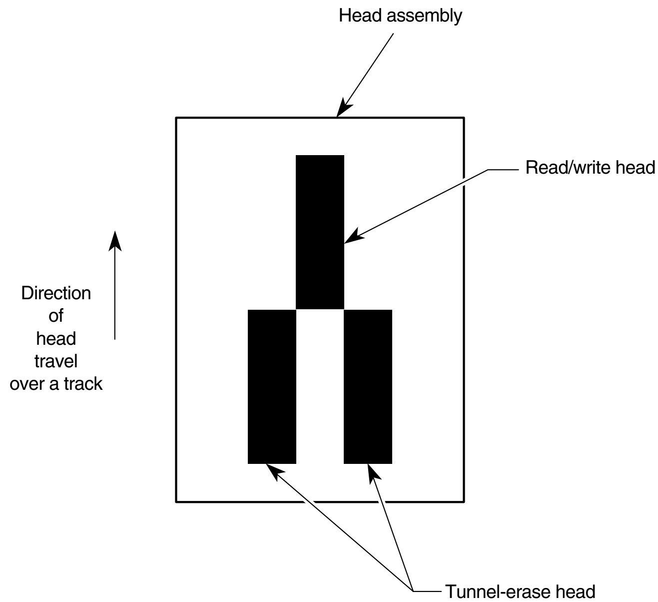

Figure 11.3 Composite construction of a typical floppy disk drive head.

To read and write to the disk properly, the heads must be in direct contact with the magnetic medium. Very small particles of loose oxide, dust, dirt, smoke, fingerprints, or hair can cause problems with reading and writing the disk. Disk and drive manufacturers' tests have found that a spacing as little as .000032 inch (32 millionths of an inch) between the heads and medium can cause read/write errors. You now can understand why it is important to handle disks carefully and avoid touching or contaminating the surface of the disk medium in any way. The rigid jacket and protective shutter for the head access aperture on 3 1/2-inch disks is excellent for preventing problems caused by contamination. Disks that are 5 1/4-inch do not have the same protective elements, which is perhaps one reason why they have fallen into disuse. If you still use 5 1/4-inch floppy disks, you should exercise extra care in their handling.

The Head Actuator

The *head actuator* for a floppy disk drive is what moves the heads across the disk and is driven by a special kind of motor, called a *stepper motor* (see Figure 11.4). This type of motor does not spin around continuously; rather, the motor turns a precise specified distance and stops. Stepper motors are not infinitely variable in their positioning; they move in fixed increments—or *detents*—and must stop at a particular detent position. This is ideal for disk drives because the location of each track on the disk can then be defined by moving one or more increments of the motor's motion. The disk controller can instruct the motor to position itself any number of steps within the range of its travel. To position the heads at cylinder 25, for example, the controller instructs the motor to go to the 25th detent position or step from Cylinder 0.

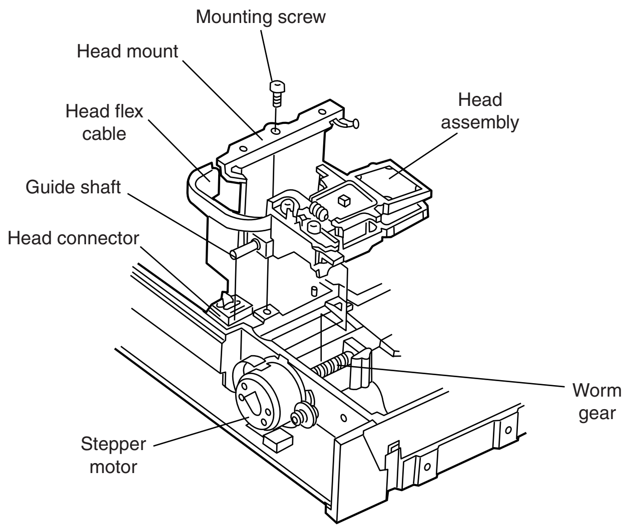

Figure 11.4 An expanded view of a stepper motor and head actuator.

The stepper motor can be linked to the head rack in one of two ways. In the first, the link is a coiled, split-steel band. The band winds and unwinds around the spindle of the stepper motor, translating the rotary motion into linear motion. Some drives, however, use a worm-gear arrangement rather than a band. In this type of drive, the head assembly rests on a worm gear driven directly off the stepper motor shaft. Because this arrangement is more compact, you normally find worm-gear actuators on the smaller 3 1/2-inch drives.

Most stepper motors used in floppy disk drives can step in specific increments that relate to the track spacing on the disk. Older 48-track-per-inch (TPI) drives have a motor that steps in increments of 3.6 degrees. This means that each 3.6 degrees of stepper motor rotation moves the heads from one track to the next. Most 96 or 135 TPI drives have a stepper motor that moves in 1.8-degree increments, which is exactly half of what the 48 TPI drives use. Sometimes you see this information actually printed or stamped right on the stepper motor itself, which is useful if you are trying to figure out which type of drive you have. 5 1/4-inch 360KB drives are the only 48 TPI drives that use the 3.6 degree increment stepper motor. All other drive types normally use the 1.8-degree stepper motor. On most drives, the stepper motor is a small cylindrical object near one corner of the drive.

A stepper motor usually has a full travel time of about 1/5 of a second—about 200ms. On average, a half-stroke is 100ms, and a one-third stroke is 66ms. The timing of a one-half or one-third stroke of the head-actuator mechanism is often used to determine the reported average access time for a disk drive. Average access time is the normal amount of time the heads spend moving at random from one track to another.

The Spindle Motor

The *spindle motor* is what spins the disk. The normal speed of rotation is either 300rpm or 360rpm, depending on the type of drive. The 5 1/4-inch high-density (HD) drive is the only drive that spins at 360rpm. All others, including the 5 1/4-inch double-density (DD), 3 1/2-inch DD, 3 1/2-inch HD, and 3 1/2-inch extra-high density (ED) drives, spin at 300rpm. This is a slow speed when compared to a hard disk drive, which helps explain why floppy disk drives have much lower data transfer rates. However, this slow speed also enables the drive heads to be in physical contact with the disk while it is spinning, without causing friction damage.

Many earlier drives used a mechanism by which the spindle motor physically turned the disk spindle with a belt, but all modern drives use a direct-drive system with no belts. The direct-drive systems are more reliable and less expensive to manufacture, as well as smaller in size. The earlier belt-driven systems did have more rotational torque available to turn a sticky disk because of the torque multiplication factor of the belt system. Most newer direct-drive systems, on the other hand, use an automatic torque-compensation capability that sets the disk-rotation speed to a fixed 300rpm or 360rpm and compensates with additional torque for high-friction disks or less torque for more slippery ones. Besides compensating for varying amounts of friction, this arrangement eliminates the need to adjust the rotational speed of the drive, something that was frequently required on older drives.

Circuit Boards

A disk drive always incorporates one or more *logic boards*, which are circuit boards that contain the circuitry used to control the head actuator, read/write heads, spindle motor, disk sensors, and other components on the drive. The logic board implements the drive's interface to the controller board in the system unit.

The standard interface used by all PC floppy disk drives is termed the Shugart Associates SA-400 interface, which was invented in the 1970s and is based on the NEC 765 controller chip. All modern floppy controllers contain circuits that are compatible with the original NEC 765 chip. This industry-standard interface is why you can purchase drives from almost any manufacturer and they will all be compatible.

The Controller

At one time, the controller for a computer's floppy disk drives took the form of a dedicated expansion card installed in an Industry Standard Architecture (ISA) bus slot. Later implementations used a multifunction card that provided the IDE/ATA, parallel, and serial port interfaces in addition to the floppy disk drive controller. Today's PCs have the floppy controller integrated into the motherboard, usually in the form of a Super I/O chip that also includes the serial and parallel interfaces, among other things. Even though the floppy controller can be found in the Super I/O chip on the motherboard, it is still interfaced to the system via the ISA bus and functions exactly as if it were a card installed in an ISA slot. These built-in controllers are normally configured via the system BIOS Setup routines and can be disabled if an actual floppy controller card is going to be installed.

Whether it is built in or not, each primary floppy controller uses a standard set of system resources:

- IRQ 6 (Interrupt Request)
- DMA 2 (Direct Memory Address)
- I/O ports 3F0–3F5, 3F7 (input/output)

These system resources are standardized and generally not changeable. This normally does not present a problem because no other devices will try to use these resources (which would result in a conflict).

◄◄ See "System Resources," p. 316.

Unlike the IDE interface, the floppy disk controller has not changed much over the years. Virtually the only thing that has changed is the controller's maximum speed. As the data density of floppy disks (and their capacity) has increased over the years, the controller speed has had to increase, as well. Nearly all floppy disk controllers in computers today support speeds of up to 1Mbit/sec, which supports all the standard floppy disk drives. 500Kbit/sec controllers can support all floppy disk drives except for the 2.88MB extra high-density models. Older computers used 250Kbit/sec controllers that could support only 360KB 5 1/4-inch and 720KB 3 1/2-inch drives. To install a standard 1.44MB 3 1/2-inch drive in an older machine you might have to replace the floppy controller with a faster model.

Tip

The best way to determine the speed of the floppy disk drive controller in your computer is to examine the floppy disk drive options provided by the system BIOS.

◀◀ See Chapter 5, "BIOS," p. 345.

Even if you do not intend to use a 2.88MB floppy disk drive, you still might want to ensure that your computer has the fastest possible controller. Some of the tape drives on the market use the floppy disk interface to connect to the system, and in this case, the controller has a profound effect on the overall throughput of the tape drive.

The Faceplate

The *faceplate*, or *bezel*, is the plastic piece that comprises the front of the drive. This piece, usually removable, comes in various colors and configurations.

Most floppy drive manufacturers offer drives with matching faceplates in gray, beige, or black and with a choice of red, green, or yellow activity LEDs as well. This enables a system builder to better match the drive to the aesthetics of the case for a seamless, integrated, and more professional look.

Connectors

Nearly all floppy disk drives have two connectors—one for power to run the drive and the other to carry the control and data signals to and from the drive. These connectors are fairly standardized in the computer industry. A 4-pin in-line connector (called Mate-N-Lock by AMP) in both large and small styles is used for power (see Figure 11.5), and a 34-pin connector in both edge and pin header designs is used for the data and control signals. Normally, 5 1/4-inch drives use the large style power connector and the 34-pin edge-type connector, whereas most 3 1/2-inch drives use the smaller version of the power connector and the 34-pin header-type logic connector. The drive controller and logic connectors and pinouts are detailed later in this chapter, as well as on the Vendor List on this book's CD-ROM.

Both the large and small power connectors from the power supply are female plugs. They plug into the male portion, which is attached to the drive itself. One common problem with upgrading an older system with 3 1/2-inch drives is that your power supply has only the large-style connectors, whereas the drive has the small style. An adapter cable is available, from Radio Shack (cat. no. 278-765) and other sources, which converts the large-style power connector to the proper small style used on most 3 1/2-inch drives.

Most standard PCs use 3 1/2-inch drives with a 34-pin signal connector and a separate small-style power connector. For older systems, many drive manufacturers also sell 3 1/2-inch drives installed in a 5 1/4-inch frame assembly with a special adapter built in that enables you to use the larger power connector and older edge-type signal connectors.

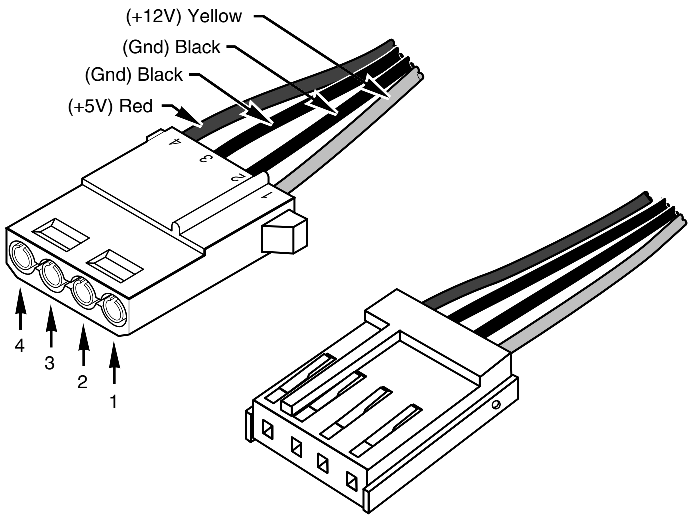

Figure 11.5 Large (5.25" drive) and small (3.5" drive) disk drive female power supply cable connectors.

The Floppy Disk Drive Cable

The 34-pin connector on a floppy disk drive takes the form of either an edge connector (on 5 1/4-inch drives) or a pin connector (on 3 1/2-inch drives). The pinouts for the connector are shown in Table 11.1.

Table 11.1 Pinouts for the Standard Floppy Disk Drive Connector

Pin	Signal	Pin	Signal
1	Ground	2	Density Select
3	Ground	4	Reserved (Unused)
5	Ground	6	Reserved (Unused)
7	Ground	8	Index
9	Ground	10	Motor Enable A
11	Ground	12	Drive Select B
13	Ground	14	Drive Select A
15	Ground	16	Motor Enable B
17	Ground	18	Direction (Stepper motor)
19	Ground	20	Step Pulse
21	Ground	22	Write Data
23	Ground	24	Write Enable
25	Ground	26	Track 0
27	Ground	28	Write Protect
29	Ground	30	Read Data
31	Ground	32	Head Select
33	Ground	34	Disk Change

The cable used to connect the floppy disk drive(s) to the controller on the motherboard is quite strange. To support various drive configurations, the cable typically has five connectors on it—two edge connectors and two pin connectors to attach to the drives and one pin connector to connect to the controller. The cable has redundant connectors for each of the two drives (A and B) supported by the standard floppy disk drive controller, so you can install any combination of 5 1/4-inch and 3 1/2-inch drives (see Figure 11.6).

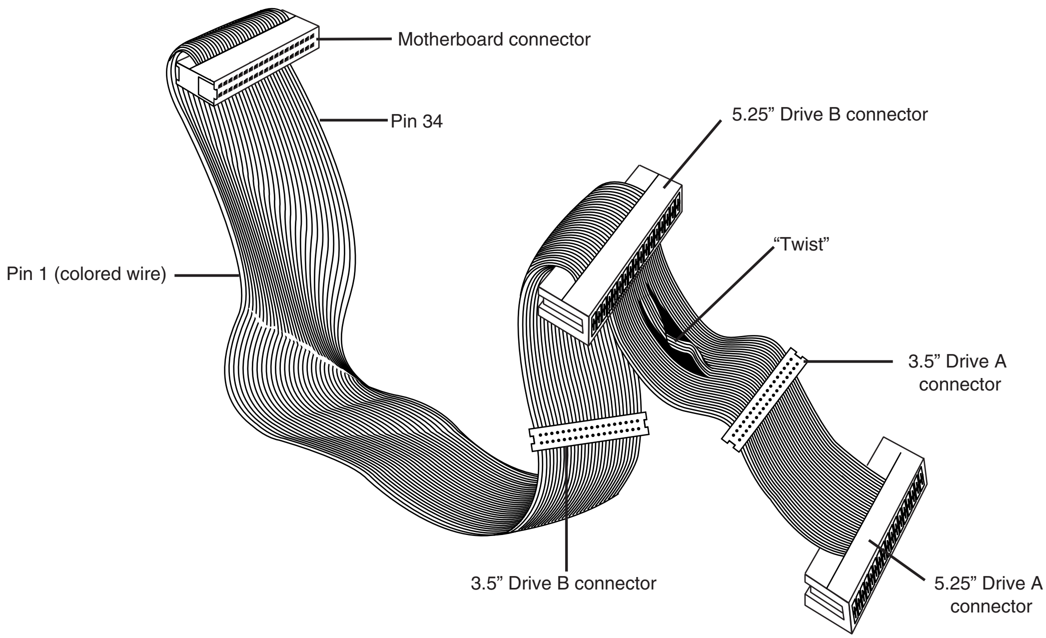

Figure 11.6 Standard five-connector floppy interface cable.

In addition to the connectors, the cable on most systems has a special twist that inverts the signals of wires 10–16. These are the wires carrying the Drive Select (DS) and Motor Enable signals for each of the two drives. Floppy disk drives have DS jumpers designed to enable you to select whether a given drive should be recognized as A or B.

You might not even know that these jumpers exist because the twist in the cable prevents you from having to adjust them. When installing two floppy disk drives in one system (admittedly a rarity nowadays), the cable electrically changes the DS configuration of the drive that is plugged in after the twist. Thus, the twist causes a drive physically set to the second DS position (B) to appear to the controller to be set to the first DS position (A) and vice versa. The adoption of this cable has enabled the use of a standard jumper configuration for all floppy disk drives, regardless of whether you install one or two drives in a computer.

If you install only a single floppy disk drive, you use the connector after the twist, which causes the drive to be recognized as drive A.

Disk Physical Specifications and Operation

Most PCs sold today are equipped with a 3 1/2-inch 1.44MB floppy disk drive. You might run into an older system that has a 5 1/4-inch 1.2MB drive instead of, or in addition to, the 3 1/2-inch drive. In addition, some PC systems have a 2.88MB 3 1/2-inch drive that can also read and write 1.44MB disks. The older drive types—5 1/4-inch 360KB and 3 1/2-inch 720KB—are obsolete and rarely found anymore.

The physical operation of a disk drive is fairly simple to describe. The disk rotates in the drive at either 300rpm or 360rpm. Most drives spin at 300rpm; only the 5 1/4-inch 1.2MB drives spin at 360rpm. With the disk spinning, the heads can move in and out approximately one inch and write 80 tracks. The tracks are written on both sides of the disk and are therefore sometimes called *cylinders*. A single cylinder comprises the tracks on the top and bottom of the disk. The heads record by using a tunnel-erase procedure that writes a track to a specified width, and then erases the edges of the track to prevent interference with any adjacent tracks.

Different drives record tracks at different widths. Table 11.2 shows the track widths in both millimeters and inches for the various types of floppy disk drives found in modern PC systems.

Table 11.2 Floppy Disk Drive Track-Width Specifications

Drive Type	No. of Tracks	Track Width	
5 1/4-in. 360KB	40 per side	0.300mm	0.0118 in.
5 1/4-in. 1.2MB	80 per side	0.155mm	0.0061 in.
3 1/2-in. 720KB	80 per side	0.115mm	0.0045 in.
3 1/2-in. 1.44MB	80 per side	0.115mm	0.0045 in.
3 1/2-in. 2.88MB	80 per side	0.115mm	0.0045 in.

How the Operating System Uses a Disk

To the operating system, data on your PC disks is organized in tracks and sectors, just as on a hard disk drive. *Tracks* are narrow, concentric circles on a disk. *Sectors* are pie-shaped slices of the individual tracks.

Table 11.3 summarizes the standard disk formats for PC floppy disk drives.

Table 11.3 5 1/4-Inch and 3 1/2-Inch Floppy Disk Drive Formats

5 1/4-Inch Floppy Disks	Double-Density 360KB (DD)	High-Density 1.2MB (HD)
Bytes per sector	512	512
Sectors per track	9	15
Tracks per side	40	80
Sides	2	2
Capacity (kilobytes)	360	1,200
Capacity (megabytes)	0.352	1.172
Capacity (million bytes)	0.369	1.229

Table 11.3 Continued

3 1/2-Inch Floppy Disks	Double-Density 720KB (DD)	High-Density 1.44MB (HD)	Extra High-Density 2.88MB (ED)
Bytes per sector	512	512	512
Sectors per track	9	18	36
Tracks per side	80	80	80
Sides	2	2	2
Capacity (kilobytes)	720	1,440	2,880
Capacity (megabytes)	0.703	1.406	2.813
Capacity (million bytes)	0.737	1.475	2.949

You can calculate the capacity differences between various formats by multiplying the sectors per track by the number of tracks per side together with the constants of two sides and 512 bytes per sector.

Note that the floppy disk's capacity can actually be expressed in various ways. The traditional method is to refer to the capacity of a floppy by the number of kilobytes (1,024 bytes equals 1KB). This works fine for the old-style 360KB and 720KB disks but is strange when applied to the 1.44MB and 2.88MB disks. As you can see, a 1.44MB disk is really 1,440KB and not actually 1.44 megabytes. Because a megabyte is 1,024KB, what we call a 1.44MB disk actually has a capacity of 1.406MB.

Another way of expressing disk capacity is in millions of bytes. In that case, the 1.44MB disk has 1.475 million bytes of capacity.

Note

Again, as with hard disk drives, both megabyte and millions of bytes are abbreviated as MB or M, often resulting in a great deal of confusion.

Like blank sheets of paper, new, unformatted disks contain no information. Formatting a disk is similar to adding lines to the paper so you can write straight across. Formatting the disk writes the information the operating system needs to maintain a directory and file table of contents. On a floppy disk, no distinction exists between a high-level and low-level format, nor do you have to create any partitions. When you format a floppy disk with Windows 9x Explorer or the DOS FORMAT.COM program, both the high- and low-level formats are performed at the same time.

When you format a floppy disk, the operating system reserves the track nearest to the outside edge of a disk (track 0) almost entirely for its purposes. Track 0, Side 0, Sector 1 contains the DOS Boot Record (DBR), or Boot Sector, that the system needs to begin operation. The next few sectors contain the file allocation tables (FATs), which keep records of which clusters or allocation units on the disk contain file information and which are empty. Finally, the next few sectors contain the root directory, in which the operating system stores information about the names and starting locations of the files on the disk.

Note that most floppies today are sold preformatted. This saves time because the formatting can take a minute or more per disk. Even if disks come preformatted, they can always be reformatted later.

Cylinders

The cylinder number is usually used in place of the track number because all floppy drives today are double-sided. A cylinder on a floppy disk includes two tracks: the one on the bottom of the disk above Head 0, and the one on the top of the disk below Head 1. Because a disk cannot have more than two sides and the drive has two heads, there are always two tracks per cylinder for floppy disks. Hard disk drives, on the other hand, can have multiple disk platters—each with two heads—resulting in many tracks per single cylinder. The simple rule is that there are as many tracks per cylinder as there are heads on the drive.

Cylinders are discussed in more detail in Chapter 10, "Hard Disk Storage," and Chapter 25, "File Systems and Data Recovery."

Clusters or Allocation Units

A *cluster* also is called an *allocation unit* in DOS version 4.0 and higher. The term is appropriate because a single cluster is the smallest unit of the disk that DOS can allocate when it writes a file. A cluster or allocation unit consists of one or more sectors—usually a power of two (1, 2, 4, 8, and so on). Having more than one sector per cluster reduces the FAT size and enables DOS to run more quickly because it has fewer individual clusters to manage. The tradeoff is in some wasted disk space. Because DOS can manage space only in the cluster size unit, every file consumes space on the disk in increments of one cluster.

For more information on allocation units, see Chapter 25.

Table 11.4 lists the default cluster sizes used by DOS and Windows for various floppy disk formats.

Table 11.4 Default Cluster and Allocation Unit Sizes

Floppy Disk Capacity	Cluster/Allocation Unit Size		FAT Type
5 1/4-in., 360KB	2 sectors	1,024 bytes	12-bit
5 1/4-in., 1.2MB	1 sector	512 bytes	12-bit
3 1/2-in., 720KB	2 sectors	1,024 bytes	12-bit
3 1/2-in., 1.44MB	1 sector	512 bytes	12-bit
3 1/2-in., 2.88MB	2 sectors	1,024 bytes	12-bit

KB = 1,024 bytes

MB = 1,048,576 bytes

Disk Change

The standard PC floppy controller and drive use a special signal on pin 34 called *Disk Change* to determine whether the disk has been changed—or more accurately, to determine whether the same disk loaded during the previous disk access is still in the drive. Disk Change is a pulsed signal that changes a status register in the controller to let the system know that a disk has been either inserted or ejected. This register is set to indicate that a disk has been inserted or removed (changed) by default.

The register is cleared when the controller sends a step pulse to the drive and the drive responds, acknowledging that the heads have moved. At this point, the system knows that a specific disk is in the drive. If the Disk Change signal is not received before the next access, the system can assume that the same disk is still in the drive. Any information read into memory during the previous access can therefore be reused without rereading the disk.

Because of this process, systems can buffer or cache the contents of the FAT or directory structure of a disk in the system's memory. By eliminating unnecessary rereads of these areas of the disk, the apparent speed of the drive is increased. If you move the door lever or eject button on a drive that supports the Disk Change signal, the DC pulse is sent to the controller, thus resetting the register and indicating that the disk has been changed. This procedure causes the system to purge buffered or cached data that had been read from the disk because the system then cannot be sure that the same disk is still in the drive.

One interesting problem can occur when certain drives are installed in a 16-bit or greater system. As mentioned, some drives use pin 34 for a "Ready" (RDY) signal. The RDY signal is sent whenever a disk is installed and rotating in the drive. If you install a drive that has pin 34 set to send RDY, the system "thinks" it is continuously receiving a Disk Change signal, which causes problems. Usually, the drive fails with a Drive Not Ready error and is inoperable. The only reason the RDY signal exists on some drives is that it happens to be a part of the standard Shugart SA-400 disk interface; however, it has never been used in PC systems.

The biggest problem occurs if the drive should be sending the DC signal on pin 34 but isn't. If a system is told (through CMOS setup) that the drive is any type other than a 360KB (which cannot ever send the DC signal), the system expects the drive to send DC whenever a disk has been ejected. If the drive is not configured properly to send the signal, the system never recognizes that a disk has been changed. Therefore, even if you do change the disk, the system still acts as though the first disk is in the drive and holds the first disk's directory and FAT information in RAM. This can be dangerous because the FAT and directory information from the first disk can be partially written to any subsequent disks written to in the drive.

Caution

If you ever have seen a system with a floppy disk drive that shows "phantom directories" of the previously installed disk, even after you have changed or removed it, you have experienced this problem firsthand. The negative side effect is that all disks after the first one you place in this system are in extreme danger. You likely will overwrite the directories and FATs of many disks with information from the first disk.

If it's even possible at all, data recovery from such a catastrophe can require quite a bit of work with utility programs, such as Norton Utilities. These problems with Disk Change most often are traced to an incorrectly configured drive.

If the drive you are installing is a 5 1/4-inch 1.2MB or 3 1/2-inch 720KB, 1.44MB, or 2.88MB drive, be sure to set pin 34 to send the Disk Change (DC) signal. Most drives come permanently preset this way, but some have used a jumper (usually labeled DC) to set this option.

Types of Floppy Disk Drives

The characteristics of the floppy disk drives you might encounter in PC-compatible systems are summarized in Table 11.5. As you can see, the different disk capacities are determined by several parameters, some of which seem to remain constant on all drives, although others change from drive to drive. For example, all drives use 512-byte physical sectors, which is true for hard disks as well.

Table 11.5 Floppy Disk Logical Formatted Parameters

	Current Formats					Obsolete Formats		
Disk Size (Inches)	**3 1/2**	**3 1/2**	**3 1/2**	**5 1/4**	**5 1/4**	**5 1/4**	**5 1/4**	**5 1/4**
Disk Capacity (KB)	**2,880**	**1,440**	**720**	**1,200**	**360**	**320**	**180**	**160**
Media descriptor byte	F0h	F0h	F9h	F9h	FDh	FFh	FCh	FEh
Sides (heads)	2	2	2	2	2	2	1	1
Tracks per side	80	80	80	80	40	40	40	40
Sectors per track	36	18	9	15	9	8	9	8
Bytes per sector	512	512	512	512	512	512	512	512
Sectors per cluster	2	1	2	1	2	2	1	1
FAT length (sectors)	9	9	3	7	2	1	2	1
Number of FATs	2	2	2	2	2	2	2	2
Root dir. length (sectors)	15	14	7	14	7	7	4	4
Maximum root entries	240	224	112	224	112	112	64	64
Total sectors per disk	5,760	2,880	1,440	2,400	720	640	360	320
Total available sectors	5,726	2,847	1,426	2,371	708	630	351	313
Total available clusters	2,863	2,847	713	2,371	354	315	351	313

The 1.44MB 3 1/2-Inch Drive

The 3 1/2-inch, 1.44MB, high-density (HD) drives first appeared from IBM in the PS/2 product line introduced in 1987. Most other computer vendors started offering the drives as an option in their systems immediately afterward. This type of floppy drive is still the most popular in systems today.

The drive records 80 cylinders consisting of 2 tracks each with 18 sectors per track, resulting in a formatted capacity of 1.44MB. Some disk manufacturers label these disks as 2.0MB, and the difference between this unformatted capacity and the formatted usable result is lost during the format. Note that the 1,440KB of total formatted capacity does not account for the areas the FAT file system reserves for file management, leaving only 1,423.5KB of actual file-storage area.

The drive spins at 300rpm, and in fact must spin at that speed to operate properly with existing high- and low-density controllers. To use the 500KHz data rate (the maximum from most standard high- and low-density floppy controllers), these drives must spin at a maximum of 300rpm. If the drives were to spin at the faster 360rpm rate of the 5 1/4-inch drives, they would have to reduce the total number of sectors per track to 15; otherwise, the controller could not keep up. In short, the 1.44MB 3 1/2-inch drives store 1.2 times the data of the 5 1/4-inch 1.2MB drives, and the 1.2MB drives spin exactly 1.2 times faster than the 1.44MB drives. The data rates used by both of these HD drives are identical and compatible with the same controllers. In fact, because these 3 1/2-inch HD drives can run at the 500KHz data rate, a controller that can support a 1.2MB 5 1/4-inch drive can also support the 1.44MB drives.

The 2.88MB 3 1/2-Inch Drive

The 3 1/2-inch, 2.88MB drive was developed by Toshiba Corporation in the 1980s and was officially announced in 1987. Toshiba began production manufacturing of the drives and disks in 1989, and several vendors began selling the drives as upgrades for their systems. IBM officially adopted these drives in its PS/2 systems in 1991, and a number of manufacturers began making them, including Toshiba, Mitsubishi, Sony, and Panasonic. Because a 2.88MB drive can fully read and write 1.44MB disks, the change is an easy one. Unfortunately, due to high media costs and a relatively low increase in data capacity, these drives never caught on widely, although virtually all systems today have built-in support for them. DOS version 5.0 or later is required to support the 2.88MB drives.

The 2.88MB extra high-density (ED) drive uses a technique called *vertical recording* to achieve its great linear density of 36 sectors per track. This technique increases density by magnetizing the domains perpendicular to the recording surface. By essentially placing the magnetic domains on their ends and stacking them side by side, the disk density increases enormously.

The technology for producing heads that can perform a vertical or perpendicular recording has been around for some time. But it is not the heads or even the drive that represent the major breakthrough in technology; rather, it is the medium that is special. Standard disks have magnetic particles shaped like tiny needles that lie on the surface of the disk. Orienting these acicular particles in a perpendicular manner to enable vertical recording is very difficult. The particles on a barium-ferrite floppy disk are shaped like tiny, flat, hexagonal platelets that can more easily be arranged to have their axes of magnetization perpendicular to the plane of recording.

Toshiba perfected a glass-crystallization process for manufacturing the ultra-fine platelets used in coating the barium-ferrite disks. This technology, patented by Toshiba, is being licensed to a number of disk manufacturers, all of whom are producing barium-ferrite disks using Toshiba's process. Toshiba also made certain modifications to the design of standard disk drive heads to enable them to read and write the new barium-ferrite disks, as well as standard cobalt or ferrite disks. This technology is being used not only in floppy disk drives, but also in a variety of tape drive formats.

The disks are called 4MB disks in reference to their unformatted capacity. The actual formatted capacity is 2,880KB, or 2.88MB. Because of space lost in the formatting process—as well as space occupied by the volume boot sector, FATs, and root directory—the total usable storage space is 2,863KB.

To support the 2.88MB drive, modifications to the disk controller circuitry were required because these drives spin at the same 300rpm but have an astonishing 36 sectors per track. Because all floppy disks are formatted with consecutively numbered sectors (1:1 interleave), the drive must read and write 36 sectors in the same time it takes a 1.44MB drive to read and write 18 sectors. This requires that the controller support a much higher data transmission rate of 1MHz (1 million bps). Most older floppy controllers support only the maximum data rate of 500KHz used by the 1.44MB drives. To upgrade to a 2.88MB drive, the controller must be changed to one that supports the higher 1MHz data rate.

An additional support issue is the ROM BIOS. The BIOS must have support for the controller and the capability to specify and accept the 2.88MB drive as a CMOS setting.

Virtually all modern PCs have built-in floppy controllers and ROM BIOS software that fully support the 2.88MB drives. Adding or upgrading to a 2.88MB drive in these systems is as easy as plugging in the drive and running the CMOS Setup program. For systems that do not have this built-in support, the upgrade process is much more difficult. Several companies offer new controllers and BIOS upgrades as well as the 2.88MB drives specifically for upgrading older systems.

The 720KB 3 1/2-Inch Drive

The 720KB, 3 1/2-inch, DD drives first appeared in an IBM system with the IBM Convertible laptop system introduced in 1986. In fact, all IBM systems introduced since that time have 3 1/2-inch drives as the standard supplied drives.

Note

Outside the PC-compatible world, other computer-system vendors (Apple, Hewlett-Packard, and so on) offered 3 1/2-inch drives for their systems two years before the PC-compatible world "caught on."

The 720KB, 3 1/2-inch, DD drive normally records 80 cylinders of 2 tracks each, with 9 sectors per track, resulting in the formatted capacity of 720KB.

PC-compatible systems have used 720KB, 3 1/2-inch DD drives primarily in XT-class systems because the drives operate from any low-density controller. The drives spin at 300rpm, and therefore require only a 250KHz data rate from the controller to operate properly. This data rate is the same as the 360KB disk drives, which means any controller that supports a 360KB drive also supports the 720KB drives.

An IBM system with a ROM BIOS date of 06/10/85 or later has built-in support for 720KB drives and requires no driver to use them. If your system has an earlier ROM BIOS date, the DRIVER.SYS program from DOS V3.2 or later—as well as the `CONFIG.SYS DRIVPARM` command in some OEM DOS versions—is all you need to provide the necessary software support to operate these drives.

The 1.2MB 5 1/4-Inch Drive

The 1.2MB high-density floppy disk drive first appeared in the IBM AT system introduced in August 1984. The drive required the use of a new type of disk to achieve the 1.2MB format capacity, but it still could read and write (although not always reliably) the lower-density 360KB disks.

The 1.2MB 5 1/4-inch drive normally recorded 80 cylinders of 2 tracks each, starting with cylinder 0 at the outside of the disk. This situation differs from the low-density 5 1/4-inch drive in its capability to record twice as many cylinders in approximately the same space on the disk. This capability alone suggests that the recording capacity for a disk would double, but that is not all. Each track normally is recorded with 15 sectors of 512 bytes each, increasing the storage capacity even more. In fact, these drives store nearly four times the data of the 360KB disks. The density increase for each track required the use of special disks with a modified medium designed to handle this type of recording. Because these disks initially were expensive and difficult to obtain, many users attempted incorrectly to use the low-density disks in the 1.2MB 5 1/4-inch drives and format them to the higher 1.2MB-density format, which resulted in data loss and unnecessary data-recovery operations.

A compatibility problem with the 360KB drives stems from the 1.2MB drive's capability to write twice as many cylinders in the same space as the 360KB drives. The 1.2MB drives position their heads over the same 40 cylinder positions used by the 360KB drives through *double stepping*, a procedure in which the heads are moved every 2 cylinders to arrive at the correct positions for reading and writing the 40 cylinders on the 360KB disks. The problem is that because the 1.2MB drive normally must write 80 cylinders in the same space in which the 360KB drive writes 40, the heads of the 1.2MB units had to be made dimensionally smaller. These narrow heads can have problems overwriting tracks produced by a 360KB drive that has a wider head because the narrower heads on the 1.2MB drive cannot "cover" the entire track area written by the 360KB drive.

The 1.2MB 5 1/4-inch drives spin at 360rpm, or six revolutions per second, or 166.67ms per revolution. The drives spin at this rate no matter what type of disk is inserted—either low- or high-density.

To send or receive 15 sectors (plus required overhead) six times per second, a controller must use a data transmission rate of 500,000bps (500KHz). All standard high- and low-density controllers support this data rate and, therefore, these drives.

This support also depends on proper ROM BIOS support of the controller in this mode of operation. When a standard 360KB disk is running in an HD drive, it also is spinning at 360rpm. A data rate of 300,000bps (300KHz), therefore, is required to work properly. All standard AT-style low- and high-density controllers support the 250KHz, 300KHz, and 500KHz data rates. The 300KHz rate, however, is used only for HD 5 1/4-inch drives reading or writing to low-density 5 1/4-inch disks.

The 360KB 5 1/4-Inch Drive

The 5 1/4-inch double-density drive is designed to create a standard-format disk with 360KB capacity. The term "double-density" arose from the use of the term "single-density" to indicate a type of drive that used frequency modulation (FM) encoding to store approximately 90KB on a disk. This type of obsolete drive never was used in any PC-compatible systems, but was used in some older systems, such as the original Osborne-1 portable computer. When drive manufacturers changed the drives to use modified frequency modulation (MFM) encoding, they began using the term double-density to indicate it, as well as the (approximately doubled) increase in recording capacity realized from this encoding method.

The 360KB 5 1/4-inch drives spin at 300rpm, which equals exactly five revolutions per second, or 200ms per revolution. All standard floppy controllers support a 1:1 interleave, in which each sector on a specific track is numbered (and read) consecutively. To read and write to a disk at full speed, a controller sends data at a rate of 250,000bps.

Analyzing Floppy Disk Construction

The 5 1/4-inch and 3 1/2-inch disks each have unique construction and physical properties. The flexible (or floppy) disk is contained within a plastic jacket. The 3 1/2-inch disks are covered by a more rigid jacket than are the 5 1/4-inch disks. The disks within the jackets, however, are virtually identical except, of course, for size.

When you look at a typical 5 1/4-inch floppy disk, you see several things (see Figure 11.7). Most prominent is the large, round hole in the center. When you close the disk drive's "door," a cone-shaped clamp grabs and centers the disk through the center hole. Many disks come with *hub-ring reinforcements*—thin, plastic rings that help the disk withstand the mechanical forces of the clamping mechanism. The HD disks usually lack these reinforcements because the difficulty in accurately placing them on the disk means they can cause alignment problems.

On the right side, just below the center of the hub hole, is a smaller round hole called the *index hole*. If you carefully turn the disk within its protective jacket, you can see a small hole in the disk itself. The drive uses the index hole as the starting point for all the sectors on the disk—sort of the "prime meridian" for the disk sectors. A disk with a single index hole is a soft-sectored disk; the software (operating system) decides the actual number of sectors on the disk. Some older equipment, such as Wang word processors, use hard-sectored disks, which have an index hole to demarcate individual sectors. Do not use hard-sectored disks in a PC.

Below the hub hole is a slot shaped somewhat like a long racetrack through which you can see the disk surface. The disk drive heads read and write data to the disk surface through this media-access hole.

On the right side, about one inch from the top, is a rectangular punch from the side of the disk cover. If this write-enable notch is present, writing to the disk has been enabled. Disks without this notch (or with the notch taped over) are write-protected disks. The notch might not be present on all disks, particularly those purchased with programs on them.

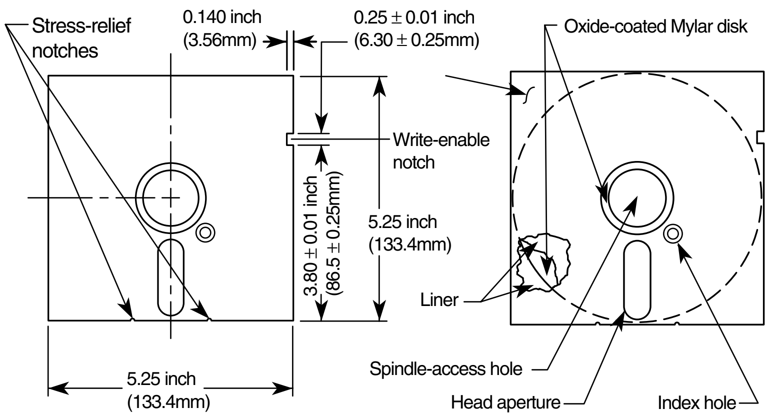

Figure 11.7 Construction of a 5 1/4-inch floppy disk.

On the rear of the disk jacket at the bottom, two very small oval notches flank the head slot. These notches relieve stress on the disk and help prevent it from warping. The drive might also use these notches to assist in keeping the disk in the proper position in the drive.

Because the 3 1/2-inch disks use a much more rigid plastic case, which helps stabilize the magnetic medium inside, these disks can record at track and data densities greater than the 5 1/4-inch disks (see Figure 11.8). A metal shutter protects the media-access hole. The drive manipulates the shutter, leaving it closed whenever the disk is not in a drive. The medium is then completely insulated from the environment and from your fingers. The shutter also obviates the need for a disk jacket.

Because the shutter is not necessary for the disk to work, you can remove it from the plastic case if it becomes bent or damaged. Pry it off the disk case; it will pop off with a snap. You also should remove the spring that pushes it closed. Additionally, after removing the damaged shutter, you should copy the data from the damaged disk to a new one.

Rather than an index hole in the disk, the 3 1/2-inch disks use a metal center hub with an alignment hole. The drive "grasps" the metal hub, and the hole in the hub enables the drive to position the disk properly.

On the lower-left part of the disk is a hole with a plastic slider—the write-protect/enable hole. When the slider is positioned so the hole is visible, the disk is *write-protected*—the drive is prevented from recording on the disk. When the slider is positioned to cover the hole, writing is enabled, and you can save data to the disk. For more permanent write-protection, some commercial software programs are supplied on disks with the slider removed so you cannot easily enable recording on the disk. This is exactly opposite of a 5 1/4-inch floppy, in which covered means write-protected, not write-enabled.

On the other (right) side of the disk from the write-protect hole, usually is another hole called the media-density-selector hole. If this hole is present, the disk is constructed of a special medium and is therefore an HD or ED disk. If the media-sensor hole is exactly opposite the write-protect hole, it indicates a 1.44MB HD disk. If the media-sensor hole is located more toward the top of the disk (the metal shutter is at the top of the disk), it indicates an ED disk. No hole on the right side means that the disk is a low-density disk. Most 3 1/2-inch drives have a media sensor that controls recording capability based on the absence or presence of these holes.

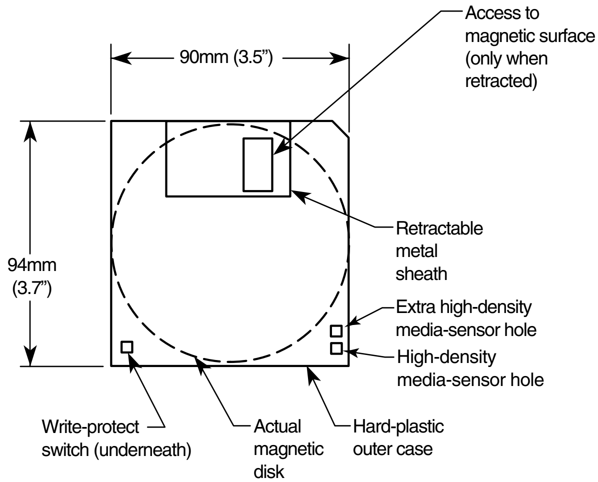

Figure 11.8 Construction of a 3 1/2-inch floppy disk.

The actual magnetic medium in both the 3 1/2-inch and 5 1/4-inch disks is constructed of the same basic materials. They use a plastic base (usually Mylar) coated with a magnetic compound. High-density disks use a cobalt-ferric compound; extended-density disks use a barium-ferric media compound. The rigid jacket material on the 3 1/2-inch disks often causes people to believe incorrectly that these disks are some sort of "hard disk" and not really a floppy disk. The disk cookie inside the 3 1/2-inch case is just as floppy as the 5 1/4-inch variety.

Floppy Disk Media Types and Specifications

This section examines the types of disks that have been available to PC owners over the years. Especially interesting are the technical specifications that can separate one type of disk from another, as Table 11.6 shows. The following sections define all the specifications used to describe a typical disk.

Table 11.6 Floppy Disk Media Specifications

	5 1/4-Inch			3 1/2-Inch		
Media Parameters	**Double-Density (DD)**	**Quad-Density (QD)**	**High-Density (HD)**	**Double-Density (DD)**	**High-Density (HD)**	**Extra High-Density (ED)**
Tracks per inch (TPI)	48	96	96	135	135	135
Bits per inch (BPI)	5,876	5,876	9,646	8,717	17,434	34,868
Media formulation	Ferrite	Ferrite	Cobalt	Cobalt	Cobalt	Barium
Coercivity (oersteds)	300	300	600	600	720	750
Thickness (micro-in.)	100	100	50	70	40	100
Recording polarity	Horiz.	Horiz.	Horiz.	Horiz.	Horiz.	Vert.

Density

Density, in simplest terms, is a measure of the amount of information that can be reliably packed into a specific area of a recording surface. The keyword here is *reliably*.

Disks have two types of densities: longitudinal density and linear density. *Longitudinal density* is indicated by how many tracks can be recorded on the disk and is often expressed as a number of tracks per inch (TPI). *Linear density* is the capability of an individual track to store data and is often indicated as a number of bits per inch (BPI). Unfortunately, these types of densities are often confused when discussing different disks and drives.

Media Coercivity and Thickness

The *coercivity* specification of a disk refers to the magnetic-field strength required to make a proper recording. Coercivity, measured in oersteds, is a value indicating magnetic strength. A disk with a higher coercivity rating requires a stronger magnetic field to make a recording on that disk. With lower ratings, the disk can be recorded with a weaker magnetic field. In other words, the lower the coercivity rating, the more sensitive the disk.

HD media demands higher coercivity ratings so the adjacent magnetic domains don't interfere with each other. For this reason, HD media is actually less sensitive and requires a stronger recording signal strength.

Another factor is the thickness of the disk. The thinner the disk, the less influence a region of the disk has on another adjacent region. The thinner disks, therefore, can accept many more bits per inch without eventually degrading the recording.

Caring for and Handling Floppy Disks and Drives

Most computer users know the basics of disk care. Disks can be damaged or destroyed easily by the following:

- Touching the recording surface with your fingers or anything else
- Writing on a disk label (which has been affixed to a disk) with a ball-point pen or pencil
- Bending the disk
- Spilling coffee or other substances on the disk
- Overheating a disk (leaving it in the hot sun or near a radiator, for example)
- Exposing a disk to stray magnetic fields

Despite all these cautions, disks are rather hardy storage devices; I can't say that I have ever destroyed one by just writing on it with a pen, because I do so all the time. I am careful, however, not to press too hard, so I don't put a crease in the disk. Also, touching a disk does not necessarily ruin a disk, but rather makes the disk and your drive head dirty with oil and dust. The real danger to your disks comes from magnetic fields that, because they are unseen, can sometimes be found in places you never imagined.

For example, all color monitors (and color TV sets) have a degaussing coil around the face of the tube that demagnetizes the shadow mask when you turn the monitor on. If you keep your disks anywhere near (within one foot of) the front of the color monitor, you expose them to a strong magnetic field every time you turn on the monitor. Keeping disks in this area is not a good idea because the field is designed to demagnetize objects, and indeed works well for demagnetizing disks. The effect is cumulative and irreversible.

Another source of powerful magnetic fields is an electric motor found in vacuum cleaners, heaters, air conditioners, fans, electric pencil sharpeners, and so on. Do not place these devices near areas where you store disks. Audio speakers also contain magnets, but most of the speakers sold for use with PCs are shielded to minimize disk corruption.

Store 3 1/2-inch disks between 40° and 127° Fahrenheit, and store 5 1/4-inch disks between 40° and 140° Fahrenheit. In both cases, humidity should not exceed 90%.

Airport X-Ray Machines and Metal Detectors

One of my favorite myths to dispel is that the airport X-ray machine somehow damages disks. I have a great deal of experience in this area from having traveled around the country for the past 20 years or so with disks and portable computers in hand. I fly about 150,000 miles per year, and my portable computer equipment and disks have been through X-ray machines hundreds of times.

X-rays are essentially just a form of light, and disks and computers are not affected by X-rays at anywhere near the levels found in these machines.

What could potentially damage your magnetic media is the metal detector. Metal detectors work by monitoring disruptions in a weak magnetic field. A metal object inserted in the field area causes the field's shape to change, which the detector observes. This principle, which is the reason the detectors are sensitive to metal objects, can be dangerous to your disks; the X-ray machine, however, is the safest area through which to pass either your disk or your computer.

The X-ray machine is not dangerous to magnetic media because it merely exposes the media to electromagnetic radiation at a particular (very high) frequency. Blue light is an example of electromagnetic radiation of a different frequency. The only difference between X-rays and blue light is in the frequency, or wavelength, of the emission.

Some people worry about the effect of X-ray radiation on their system's EPROM (erasable programmable read-only memory) chips. This concern might actually be more valid than worrying about disk damage because EPROMs are erased by certain forms of electromagnetic radiation. In reality, however, you do not need to worry about this effect either. EPROMs are erased by direct exposure to very intense ultraviolet light. Specifically, to be erased, an EPROM must be exposed to a 12,000 uw/cm^2 UV light source with a wavelength of 2,537 angstroms for 15–20 minutes, and at a distance of 1 inch. Increasing the power of the light source or decreasing the distance from the source can shorten the erasure time to a few minutes.

The airport X-ray machine is different by a factor of 10,000 in wavelength. The field strength, duration, and distance from the emitter source are nowhere near what is necessary for EPROM erasure. Many circuit-board manufacturers even use X-ray inspection on circuit boards (with components including EPROMs installed) to test and check quality control during manufacture.

Now, you might not want to take my word for it, but scientific research has been published that corroborates what I have stated. A few years ago, a study was published by two scientists—one of whom actually designs X-ray tubes for a major manufacturer. Their study was titled "Airport X-rays and Floppy Disks: No Cause for Concern" and was published in 1993 in the journal *Computer Methods and Programs in Biomedicine*. According to the abstract,

> A controlled study was done to test the possible effects of X-rays on the integrity of data stored on common sizes of floppy disks. Disks were exposed to doses of X-rays up to seven times that to be expected during airport examination of baggage. The readability of nearly 14 megabytes of data was unaltered by X-irradiation, indicating that floppy disks need not be given special handling during X-ray inspection of baggage.

In fact, the disks were retested after two years of storage, and there still has been no measurable degradation since the exposure.

Drive-Installation Procedures

In most cases, installing a floppy disk drive is a matter of physically attaching the drive to the computer chassis or case and then plugging the power and signal cables into the drive. Some types of brackets and screws are normally required to attach the drive to the chassis. These are normally included with the chassis or case itself. Several companies listed in the Vendor List on the CD-ROM specialize in cases, cables, brackets, screw hardware, and other items useful in assembling systems or installing drives.

Note

Because floppy disk drives are generally installed into the same half-height bays as hard disk drives, the physical mounting of the drive in the computer case is the same for both units. See the section "Hard Disk Installation Procedures" in Chapter 14, "Physical Drive Installation and Configuration," for more information on the process.

Troubleshooting Floppy Drives

Because of their very low cost, floppy drives have become a fairly disposable item these days. Also, their connection to the system has become simpler over the years as drives today come preconfigured with no jumpers or switches to set. The cables are fairly standardized as well. What all this means is that if the drive or cable is suspected of being defective, it should be replaced rather than repaired. This section discusses some of the most common problems floppy drives can have and how to troubleshoot them.

Problem

Dead drive—The drive does not spin and the LED never comes on.

Cause/Solution

The drive or controller is not properly configured in the BIOS setup. Check the BIOS setup for proper drive type and make sure the controller is enabled if it's built in to the motherboard.

Other causes for a dead drive include

- *Bad power supply or power cable.* Measure the power at the cable with a voltmeter, and ensure that 12v and 5v are available to the drive.
- *Bad data cable.* Replace the cable and retest.
- *Defective drive.* Replace the drive and retest.
- *Defective controller.* Replace the controller and retest. If the controller is built in to the motherboard, disable it via the BIOS setup, install a card-based controller, and retest, or replace the entire motherboard and retest.

Problem

Drive LED remains on continuously.

Cause/Solution

Data cable is on backward at either the drive or controller connection. Reinstall the cable properly and retest.

Also, the data cable could be offset on the connector by one or more pins. Reinstall the cable properly and retest. If this does not solve the problem, it could be a defective cable. Replace the cable and retest.

Problem

Phantom directories—You have exchanged disks in the drive, but the system still believes the previous disk is inserted, and even shows directories of the previous disk.

Cause/Solution

Several causes and solutions are possible:

- *Defective cable (pin 34)*. Replace the cable and retest.
- *Improper drive configuration*. If the drive is an older model and has a DC jumper, it must be set to enabled. You also should ensure the BIOS Setup has the proper drive type entered.
- *Defective drive*. Replace the drive and retest.

Common Floppy Drive Error Messages—Causes and Solutions

Error Message

`Invalid Media` or `Track Zero Bad, Disk Unusable`

Cause/Solution

You are formatting the disk and the disk media type does not match the format parameters. Make sure you are using the correct type of disk for your drive and formatting the disk to its correct capacity. Other causes and solutions are

- *Defective or damaged disk*. Replace the disk and retest.
- *Dirty heads*. Clean the drive heads and retest.

Error Message

`CRC Error` or `Disk Error 23`

Cause/Solution

The data read from the disk does not match the data that was originally written. (CRC stands for cyclic redundancy check.) Replace the disk and retest, or possibly, clean the drive heads. Use the Norton Utilities for possible data recovery from the disk.

Error Message

`General Failure Reading Drive A, Abort, Retry, Fail` or `Disk Error 31`

Cause/Solution

The disk is not formatted or has been formatted for a different operating system (Macintosh, for example). Reformat the disk and retest. Another cause could be that damaged areas exist on the disk medium. Replace the disk and retest. Use the Norton Utilities for possible data recovery from the disk.

Error Message

`Access Denied`

Cause/Solution

You are trying to write to a write-protected disk or file. Move the write-protect switch to allow writing on the disk, or remove the read-only file attribute from the files. File attributes can be changed with the `ATTRIB` command.

Error Message

`Insufficient Disk Space` or `Disk Full`

Cause/Solution

The disk is filled, or the root directory is filled. Check to see whether sufficient free space is available on the disk for your intended operation.

Error Message

`Bytes in Bad Sectors`

Cause/Solution

This is displayed after formatting or running the `CHKDSK` command and shows that the disk has several allocation units that are marked bad. This is not a problem in itself because when the allocation units are marked in this fashion, the operating system will not use them for file storage. Even so, I normally don't recommend using disks with bad sectors.

Error Message

`Disk Type or Drive Type Incompatible or Bad`

Cause/Solution

You are attempting to `DISKCOPY` between two incompatible drive or disk types. Disks can be copied only between drives using the same disk density and size.

CHAPTER 12

High-Capacity Removable Storage

Why Use Removable-Media Drives?

As operating systems and applications continue to grow in size and features, more and more storage space is needed for these programs as well as for the data they create.

A typical installation of Windows 2000 Professional can occupy close to 600MB, for example. Windows 98 or Windows Me can use more than 200MB of disk space, and the various versions of Windows require 1GB of disk space or more. And even if you install your Windows applications on a different drive, your \WINNT or \WINDOWS folder is likely to grow in size as time passes. Why? The reason is simple: Nearly all Windows applications place shared program or support files in one of the Windows directories (such as `\WINDOWS\SYSTEM`). These files include those with extensions such as DLL, 386, VBX, DRV, TTF, and many others. Even non-Windows operating systems, such as OS/2 and Linux, can also consume large amounts of space.

Operating systems aren't the only program types that are growing. Applications whose MS-DOS versions once fit on a few floppy disks have now mutated into "everything but the kitchen sink" do-it-all behemoths that can take 100MB–500MB of disk space. The multimedia revolution—fueled by powerful, low-cost digital cameras, scanners, and video recorders—enables you to capture and store images that easily can consume hundreds of megabytes of space, and the MP3 craze is filling countless gigabytes of storage on individual users' systems with digitized musical hits and classics.

Whether you're looking for additional storage you can access as an additional drive letter or as a means of backup, if you're a typical user, you need more storage today than ever before.

This section focuses on some of the more advanced data storage options on the market: high-capacity removable-media storage, including disk drives, tape drives, and flash-memory cards. This chapter focuses on magnetic, floptical, flash storage, and magneto-optical devices. Pure optical storage—such as CD-R, CD-RW, DVD-RAM, DVD+RW, DVD-RW, and others—is covered in Chapter 13, "Optical Storage."

Some removable-media drives use media as small as a 3 1/2-inch floppy disk or a type II PC Card, whereas others use larger media up to 5 1/4-inches. Most popular removable-storage drives today have capacities that range from 100MB to 70GB or more. These drives offer fairly speedy performance and the capability to store anything from a few data files or less frequently used programs to complete hard disk images on a removable disk or tape. Besides backup, this provides the capability to easily transport huge data files—computer-aided drawing (CAD) files and graphics files, for example—from one computer to another. Or, you can use a removable cartridge to take sensitive data away from your office so you can lock it safely away from prying eyes. Some types of removable-media storage feature archival durability, whereas others are designed for the "shoot it today, delete it tomorrow" world of digital photography.

Backing Up Your Data

Any computer book worth reading warns repeatedly that you should back up your system regularly. Backups are necessary because at any time a major problem, or even some minor ones, can corrupt the important information and programs stored on your computer's hard disk drive, rendering this information useless. A wide range of problems can damage the data on your hard drive. Here is a list of some of these data-damaging problems:

- *Sudden fluctuations in the electricity that powers your computer (power spikes), resulting in data damage or corruption.*
- *Overwriting a file by mistake.*
- *Mistakenly formatting your hard disk when you meant to format a floppy.*

- *Hard drive failure resulting in loss of data that has not been backed up*. Not only do you have to install a new drive, but, because you have no backup, you also must reinstall all your software.
- *Catastrophic damage to your computer (storm, flood, lightning strike, fire, theft, and so on)*. A single lightning strike near your office or home can destroy the circuitry of your computer, including your hard drive. Theft of your computer, of course, is equally devastating. A recent, complete backup greatly simplifies the process of setting up a replacement computer.
- *Loss of valuable data due to a computer-related virus*. One single download or floppy disk can contain a virus that can damage valuable files and even your entire hard disk. With several hundred new viruses appearing each month, no antivirus software program can keep you entirely safe. A recent backup of uninfected, critical files can help repair even the worst damage.

Backups are also the cure for such common headaches as a full hard drive and the need to transfer data between computers. By backing up data you rarely use and deleting the original data from your hard drive, you free up space once occupied by that data. If you later need a particular data file, you can retrieve that file from your backup. You also can more easily share large amounts of data between computers—when you send data from one city to another, for example—by backing up the data to a tape or other media and sending the media.

Regardless of how important regular backups are, many people avoid making them. A major reason for this lapse is that for many people, backing up their systems is tedious work when they have to use floppy disks or other low-capacity media. When you use these media, you might have to insert and remove many disks to back up all the important programs and data.

Optical storage, high-capacity magnetic media, and tape backups are all useful devices for making backups. Historically, tape backups have been regarded as the most powerful of these technologies because tape backups are among the few backup devices capable of recording the contents of today's multi-gigabyte drives to a single cartridge for restoration.

Comparing Disk, Tape, and Flash Memory Technologies

Several types of removable-media disk drives are commonly used. The most common varieties use magnetic media, but some use one of two combinations of magnetic and optical storage: floptical or magneto-optical. Magnetic media drives use technology similar to that of a floppy or hard disk drive to encode data for storage. Floptical and magneto-optical media drives encode information on disk by using different combinations of laser and magnetic technologies.

Flash memory devices emulate disk drives and are also discussed in this chapter. Some tape drives are also capable of emulating disk drives by providing drive letter access to a portion of the media but are used primarily to perform streaming backups of large disk drives and network drive arrays.

▶▶ See "Flash Card and Digital 'Film,'" p. 662.

Magnetic Disk Media

Whether you are looking at "pure" magnetic media, floptical media, or magneto-optical drives, all types of magnetic disk media share similar characteristics. Disk media is more expensive per megabyte or gigabyte than tape, usually has a lower capacity, and is more easily used on a file-by-file basis as compared to tape. Disk media uses random access, which enables you to find, use, modify, or delete any file or group of files on a disk without disturbing the rest of the disk's contents. Disk media is faster for copying a few files but normally slower for copying large numbers of files or entire drives.

Magnetic Tape Media

Tape media has much less expensive costs overall per megabyte or gigabyte than disk media, has a higher total capacity, and is more easily used on an image or a multiple-file basis. Tape drives use sequential access, meaning that the contents of a tape must be read from the beginning and that individual files must be retrieved in the order found on the tape. Also, individual files usually can't be modified on the tape or removed from the tape; the contents of the entire cartridge must be deleted and rewritten. Thus, tape drives are more suited for complete backups of entire hard disks including all applications and data. Because it is suited for mass backup, tape can be difficult to use for copying single files.

Note

Removable-media disk drives can be used as system backup devices similar to tape. However, the higher price of the medium itself (disks or cartridges) and the generally slower speed at which they perform can make this use somewhat prohibitive on a large scale. For file-by-file backups, disk media is ideal; if, however, you're completely backing up entire drives or systems, tape is faster and more economical.

Flash Memory Media

The newest type of removable storage is not magnetically based but uses flash memory—a special type of solid-state memory chip that requires no power to maintain its contents. Flash memory cards can easily be moved from digital cameras to notebook or desktop computers and can even be connected directly to photo printers or self-contained display units. Flash memory can be used to store any type of computer data, but its primary application is digital photography.

Tip

Literally dozens of removable storage devices are currently on the market. Be sure to compare your chosen solution against the competition before making a final purchase. Be especially wary of missing statistics in press releases and product packaging—manufacturers are apt to omit a specification if their drives don't measure up to the competition.

Comparing Removable Media Types

Table 12.1 summarizes the major features of the removable-media drives that are covered in this chapter. Because optical storage can be more suitable for some uses, the major types of optical storage are also listed for comparison.

Table 12.1 Quick Reference to Storage Devices[1]

Media Type	Media Brands	Mfrs.	Capacity	Interface Type	Best Use
Flash memory	SmartMedia; ATA Data Flash; Compact Flash; Memory Stick	Various	2MB–512MB, depending on brand and model	Proprietary; PC Card or floppy via adapters; PC Card Type II	Digital camera "film;" storage for PDAs; portable devices

Table 12.1 Continued

Media Type	Media Brands	Mfrs.	Capacity	Interface Type	Best Use
Flexible magnetic disk	Zip; LS-120 SuperDisk; PocketZip (formerly Clik!)	Various	40MB–250MB, depending on brand and model	Parallel; IDE; SCSI; USB; PC Card (PCMCIA); IEEE-1394	Data and program backups; storage for direct access
Hard disk	MicroDrive	IBM	170MB; 340MB; 512MB; 1GB	CF+ Type II; PC Card Type II via adapter	Digital camera "film;" program and data storage for notebook computers
	DataPak Type II	Kingston	260MB; 2GB	PC Card	
High-performance flexible magnetic disk	Jaz	Iomega	1GB; 2GB	SCSI	Program storage; data and program backups
High-performance hard disk cartridge	Orb	Castlewood	2.2GB	IDE; SCSI; USB; Parallel	Program storage; data and program backups
.315" magnetic tape cartridge	Travan and Travan NS	Various	Up to 10GB[2], depending on brand and model	IDE; SCSI; Parallel; USB	Data and program backups; full drive backup
ADR magnetic tape cartridge	ADR 30GB and 50GB	OnStream Data	15GB[2]; 25GB[2]	IDE; SCSI; Parallel; USB; IEEE-1394	Data and program backups; full drive backup; works-in-progress storage and playback
DAT; Exabyte 8MM; AIT DDS magnetic tape cartridge	Various	Various	Up to 50GB[2]	SCSI	Data and program backups; full drive backup

1. *In order by capacity.*

2. *Uncompressed capacity: Tape drives are usually rated at 2:1 compression; multiply uncompressed capacity by actual compression ratio obtained to determine your nominal working capacity.*

Interfaces for Removable-Media Drives

In addition, several connection options are available for the leading removable drives. The most common interface (and one of the fastest) for internally mounted drives is the same Enhanced IDE (EIDE) interface used for most hard drives. SCSI interfacing is as fast or even faster for use with either internal or external drives but requires adding an interface card to most systems. Most high-end tape backups require a SCSI interface.

The most common external interface is now the USB port, which is replacing the venerable parallel port for printing as well as interfacing low-cost external drives and other types of I/O devices. The USB port is available on virtually all recent PCs (both desktop and notebook models); can be hot-swapped; and is supported by Windows 98, Windows Me, Windows 2000, and Windows XP. Older interfaces, such as the parallel port and PC Card (for notebook computers), are still used on some devices but have limited performance. These are recommended only for systems that don't support USB (such as those still running most releases of Windows 95 or any release of Windows NT 4). Some external removable-media drives allow you to interchange interfaces to enable a single drive to work with a variety of systems.

Note

Although late versions of Windows 95 ("Win95C" or OSR2.1 and above) also have USB drivers, many developers of USB devices do not support their use with Windows 95. For reliable results and manufacturer support, use Windows 98, Windows Me, Windows 2000, or above.

As you will see in the following sections, most removable-media drives are available in two or more of these interface types, allowing you to choose the best interface option for your needs.

Note

Connecting or installing removable-media drives is similar to connecting and installing other internal and external peripherals.

The external USB, IEEE-1394, or parallel port drives are the simplest of the available interfaces, requiring only a special cable that comes with the drive and installation of special software drivers. See the instructions that come with each drive for the specifics of its installation.

See Chapter 7, "The IDE Interface"; Chapter 8, "The SCSI Interface"; and Chapter 16, "Audio Hardware," for details on how IDE, SCSI, USB, IEEE-1394, and parallel interfaces operate.

Overview of Removable Magnetic Storage Devices

A small group of companies dominates the market for magnetic removable-media drives. 3M's spin-off company Imation, Iomega, and Castlewood are the leading names in removable magnetic media drives.

Removable magnetic media drives are usually floppy or hard disk based. For example, the popular Zip drive is a 3 1/2-inch version of the original Bernoulli flexible disk drive made by Iomega. The Imation SuperDisk LS-120 drive is a floppy-based drive that stores 120MB on a disk that looks almost exactly like a 1.44MB floppy! The former SyQuest SparQ, current Iomega Jaz and Castlewood Orb drives, and the new Iomega Peerless drive system are all based on hard-disk technology.

From the standpoint of widespread industry adoption and multiple sources of media, both the Iomega LS-120 SuperDisk and Iomega Zip drives can be considered some type of industry standard. Most computer vendors offer models with either drive already installed; various models can be purchased as upgrades for existing computers; and third-party media vendors, such as Maxell, Verbatim, Sony, and Fujifilm, sell Zip and LS-120 media.

The LS-120, as you'll read shortly, can be used as a direct replacement for the 3 1/2-inch 1.44MB floppy drive, whereas the Iomega Zip drives work with only Zip media. However, because both models are so popular, the wisest choice for near-universal compatibility might be to have both drives on hand.

The following sections provide information about all types of magnetic media, including floptical and magneto-optical drive types.

Iomega Zip and PocketZip

Unlike the LS-120 SuperDisk, the Iomega Zip drive can't use standard 3 1/2-inch floppy disks. At first glance, this might make these drives a more risky choice, but what really matters is how widely the drive has been adopted. With millions sold and media available at stores ranging from drug stores to computer superstores, the Iomega Zip is among the most popular drives ever created. The Iomega Zip is a descendent of a long line of removable-media drives from Iomega that go back to the first Bernoulli cartridge drives released in the early 1980s. The Iomega PocketZip, despite the similarity in name, is actually a much smaller removable-media drive oriented toward digital cameras, MP3 music players, and data transfer between devices and computers. Both Zip and PocketZip are technologies based on flexible media and have capacities up to 250MB. Iomega's other removable-media drives—the Jaz and new Peerless drive system—offer capacities starting at 1GB and are based on hard-disk technology.

Early Iomega Bernoulli Drives

Back in the early 1980s, Iomega introduced the Bernoulli drive. The disk used in the original 10MB "Alpha" Bernoulli drive was a thick, rigid plastic cartridge roughly the same width as an 8-inch floppy disk. The 20MB "Beta" and later models used a 5 1/4-inch disk cartridge. A large shutter, similar to the shutter on a 3 1/2-inch floppy disk, easily distinguished both types of Bernoulli disks from standard floppy disks. The 5 1/4-inch Bernoulli drives were manufactured in capacities ranging from 20MB up to 230MB.

Bernoulli disks originally were known as the most durable of the removable-media drive types because the media is well protected inside the cartridge. When it rotates in the drive, the Bernoulli disk media is pulled by air pressure toward the drive heads. As the disk spins, the airflow generated by the disk movement encounters what is called a Bernoulli *plate*, which is a stationary plate designed to control the airflow so the disk is pulled toward the read/write head. At full speed, the head touches the disk, which causes wear. Bernoulli drives have built-in random seek functions that prevent any single track on the disk from wearing excessively during periods of inactivity. Bernoulli disk cartridges should be replaced periodically because they can wear out.

Note

These drives are basically obsolete, but drives, parts, service, and media for many models are still available from Comet Enterprises, LLC (`http://www.gocomet.com`, 88 North Fort Lane, Layton, UT 84041, 801-444-3600, fax 801-444-3606) and other sources.

Zip Drives

The current form of Bernoulli-technology drive from Iomega is the popular Zip drive. This device is available as an internal SCSI or IDE unit, or as an external SCSI, parallel port, or USB device. In addition, low-power PC Card or internal drive bay versions are available from various aftermarket vendors designed for use in notebook computers. Iomega also offers a USB to IEEE-1394 port adapter for the USB version of the Zip 250, enabling this model to work with IEEE-1394 ports. For a brief period, Iomega also produced a "plus" version that featured both SCSI and parallel interfaces, but this product has been discontinued.

Zip 100 drives can store up to 100MB of data on a small removable magnetic cartridge that resembles a 3 1/2-inch floppy disk. The newer Zip 250 drives store up to 250MB of data on the same size cartridge and can read and write to the Zip 100 cartridges. The latest Zip 250 cartridges have a U-shaped case and use media containing titanium particles for greater durability.

Zip drives use a proprietary 3 1/2-inch disk made by Iomega and also sold by other major media vendors, such as Maxell, Verbatim, and Fuji. It is about twice as thick as a standard 3 1/2-inch floppy disk or SuperDisk (see Figure 12.1).

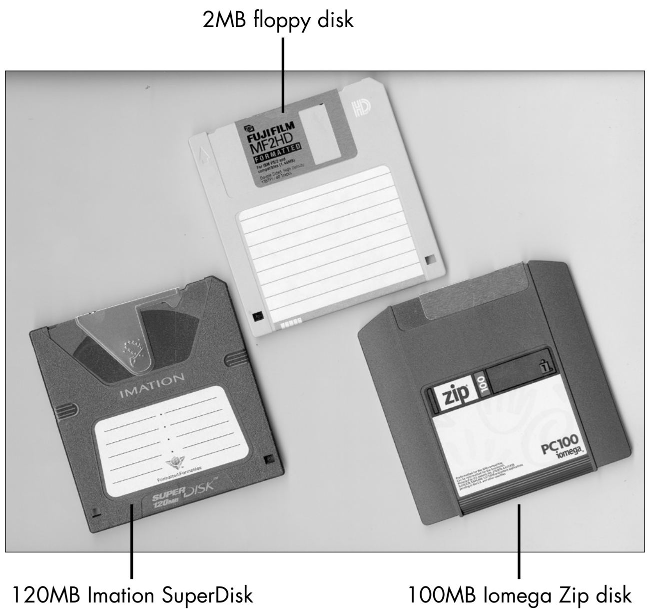

Figure 12.1 The Zip 100MB disk (right) compared to the standard 3 1/2-inch 1.44MB disk (middle) and the LS-120 SuperDisk (left). The Zip disk is thicker, has a tapered top, and has a much narrower shutter than either the LS-120 or 1.44MB disk.

The Zip drives do not accept standard 1.44MB or 720KB floppy disks, making them unlikely candidates for a floppy disk drive replacement. Internal Zip drives have become popular options in new PCs, and the external models are an effective solution for exchanging data between systems.

Tip

Recent systems support the Zip drive in their BIOS setup programs, which enables you to use the IDE version as a boot drive.

Zip drives also have suffered from reliability problems, such as the so-called "click of death," which occurs when the drive begins a rhythmic ticking sound. At this point, the data on the disk can be corrupted and both the drive and the media must be replaced.

▶▶ See "Zip Drive 'Click of Death,'" p. 644.

Table 12.2 lists the Zip 100 and Zip 250 specifications. SCSI versions of the Iomega Zip drive can be used with standard SCSI host adapters or with the Iomega Zip Zoom, a low-cost SCSI host adapter designed especially for the Zip drive.

Table 12.2 Zip 100 and Zip 250 Specifications

		Formatted Capacity	*100MB*		
Model (Interface)	**EIDE**	**USB**	**PC Card**	**Parallel**	**SCSI**
Sustained transfer rate min.	N/A	N/A	N/A	790KB/sec	790KB/sec
Sustained transfer rate max.	1.4MB/sec	1.2MB/sec	1.4MB/sec	1.4MB/sec	1.4MB/sec
Typical throughput	N/A	N/A	N/A	25MB/min	60MB/min
Average seek time	29ms	29ms	29ms	29ms	29ms
		Formatted Capacity	*250MB*		
Model (Interface)	**EIDE**	**USB**	**PC Card**	**Parallel**	**SCSI**
Sustained transfer rate max.	2.4MB/sec	900KB/sec[1]	440KB/sec	800KB/sec	2.4MB/sec
Typical throughput	N/A	55MB/min	N/A	N/A	N/A
Average seek time	29ms	<50ms	70ms	29ms	29ms

1. The USB version of the Zip 250 drive can now be connected to the Zip 250 USB FireWire (IEEE-1394) adapter made by Iomega. This device more than doubles the sustained transfer rate of the drive (from 900KB/sec to 2.0MB/sec).

Note that although the SCSI and Parallel port versions of the Zip 100 claim the same sustained transfer rate, the throughput of the SCSI drive is more than twice as fast—a fact that owners of both models can attest to. If you have a SCSI card with an external port, use the SCSI Zip drives; they're fast!

Media for the Zip 100 drive is about $9–$10 per disk in quantities. Media for the Zip 250 drive is about $17 per disk in quantities.

Figure 12.2 shows the interior of a Zip drive, listing the various components within.

The interior assembly forms a tray that is mounted on a sliding track. This allows the entire tray to move with the disk.

Iomega FotoShow

The most unusual version of the Zip drive is the FotoShow Digital Image Center, which combines the features of the Zip 250 USB drive with flash memory card and TV compatibility and a remote control.

FotoShow contains two flash memory card-reader slots, one for CompactFlash and one for SmartMedia, enabling it to read files created with most digital cameras. FotoShow copies the contents of either type of flash memory card to a Zip 100 or Zip 250 disk when you click the Copy button. You can also transfer pictures from your computer because FotoShow acts as a normal Zip 250 USB drive.

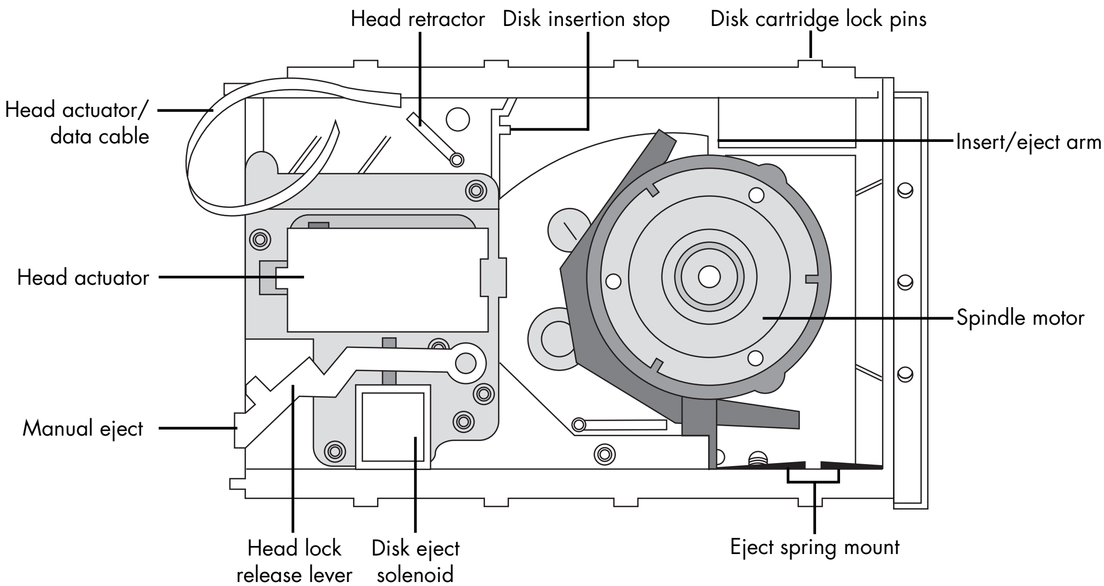

Figure 12.2 Iomega Zip drive internal view.

After you've loaded photos into a Zip disk, attach FotoShow to any NTSC (North American Broadcast Standard) TV through composite, S-Video, or RF-coaxial connectors. Use the remote control to create a slideshow from the pictures. You can also crop, rotate, and even remove red-eye from photos while they're displayed onscreen. FotoShow is compatible with the most common types of JPEG photos, including files ending in .jpg, .jpe, and .jpeg.

Zip Drive "Click of Death"

Iomega has acknowledged that as many as 100,000 users of Zip drives have suffered what is called the "click of death." The name refers to a sharp clicking sound that is heard from the drive as the heads are continually loaded and unloaded as they try to read a disk. This unfortunately means at a minimum that the disk, and possibly the drive, is likely trashed.

In fact, many users have found that the disk cartridge can be damaged in such a way that if you attempt to read it on another Zip drive, that drive will be damaged as well. The only solution is to get a new disk and drive, and to not try to read damaged disks in new drives.

If you think your drive or disk has been damaged, call Iomega technical support (see the vendor list); they should replace the defective disk and possibly the drive as well.

Iomega lists these precautions to help prevent damaged disks and drives:

- *Eject disks prior to transporting any Iomega drive*. This allows the drive heads (which read and write to the disks) to park in a natural position.
- *Avoid dropping your drive*. It can damage internal structures.
- *Be especially careful to transport and store Zip disks only in the Zip disk cases*.

Note

Iomega offers utility diagnostics software that tests the integrity of the Zip heads and Zip media. You can download this from its Web site.

Another company, Gibson Research, has developed a unique program for diagnosing problems with Zip and Jaz drives. It is called Trouble In Paradise (TIP) and can be downloaded free from the Gibson Research site. Gibson is well known as the manufacturer of the Spinrite program for hard disks. The Gibson Research Web site has a lot of additional information on the click of death and other Zip drive issues. See the vendor list for its URL and address.

Because of the high frequency of this problem, many data recovery companies have had a large business in recovering data from damaged Zip cartridges. In fact, the problem has even prompted a class action lawsuit. The law firm of Dodge, Fazio, Anderson, and Jones, P.C. announced that a nationwide class action (known as the Rinaldi lawsuit for Jason Rinaldi, the first-named member of the class) was commenced on September 10, 1998, in the Superior Court of New Castle County in Delaware on behalf of all owners of the Iomega Zip drive. The complaint contains claims for breach of warranty, negligence in manufacturing and design, consumer fraud, and failure to warn.

Investigation has shown that the click of death has three main causes:

- Magnetic particles corrupt the read/write mechanism of the drive, as well as any disk it is attempting to read.
- Lubricant on the disk decomposes, forming a solid material, which accumulates on the heads of the drive. This prevents the heads from reading the disk and subsequently corrupts it.
- The drive heads come in contact with the edge of the spinning disk, which can dislodge the drive heads or tear the storage media and render the disk useless.

This latter point is especially troublesome because if damaged media is inserted into a new drive, it can damage the new drive as well, in some cases tearing the heads off their mounts.

Tip

Before you insert a previously used Iomega Zip disk into a drive, you can check the media for damage by **carefully** sliding open the shutter on the disk and rotating the media using the spindle at the bottom of the disk. If you see roughness or damage, contact Iomega or the media vendor for replacement.

Note also that if you purchase brand-new media in bulk from a store that uses magnetic antitheft strips that must be demagnetized before you leave the store, the Zip media can be demagnetized as well. Return such media to the store for replacement.

Data recovery from a damaged Zip disk can cost $400 or more, so I suggest you keep backups of any important data you store on these disks, and if your drive starts clicking, don't use media with any data already onboard to test it.

A proposed settlement for the Rinaldi lawsuit was announced on March 21, 2001; offers rebates to **all** Zip drive owners who purchased drives between January 1, 1995 and March 19, 2001. The proposed settlement offers rebates on future purchases of Zip and Pocket Zip drives and media. Users who certify that their drives were affected by the click of death will receive higher amounts for their rebates.

If you have not received information on the settlement, you can read the details of the settlement and receive a copy of the notice by going to the Iomega Web site (`www.iomega.com`), following the Rinaldi Class Action Settlement link and downloading the notice form.

As mentioned before, the new U250 cartridges from Iomega have been redesigned to use titanium particles in the media. This improvement in media design should significantly improve operations of the drives. The U250 cartridge is also self-cleaning to improve reliability of the cartridge and the Zip 250 drive.

Click of death problems can still occur with Zip drives and, to a lesser extent, with Jaz drives as well. Users of these drives should regularly test their drives and media with Iomega's diagnostics supplied with the drives and the Gibson Research TIP program to avoid problems.

Iomega PocketZip

One of the newer products in Iomega's current line of removable-media drives is now called the PocketZip drive, although you might have first heard of this drive when it was called the Clik! drive. Despite the name, this product doesn't use the same mechanism or cartridges as the Zip. Its tiny dimensions (2"×2") and capacity (40MB) position it as a product intended primarily for digital cameras and notebook computers. A new version of the PocketZip drive featuring 100MB storage is scheduled to be introduced during the fourth quarter of 2001.

The PocketZip drive, unlike other magnetic removable-media drives discussed earlier, is not built directly into a computer. It is designed to act as a bridge between flash memory devices and computers, using the PocketZip Card Dock. The USB-based Card Dock also uses CompactFlash and IBM MicroDrive media, enabling you to transfer data from these media types to a PocketZip disk, and then from PocketZip to your computer. Iomega also offers a PocketZip PC Card drive, enabling you to transfer data via a notebook's Type II PC Card slots. PocketZip also works with Iomega's HipZip portable audio player.

Using PocketZip

PocketZip can be used to share information between notebook computers by inserting the PocketZip Card into the PocketZip PC Card drive, which fits into a standard Type II PC Card (PCMCIA) slot. The PocketZip USB drive can accept PocketZip cartridges and connects with any PC or Mac with a USB port. The PocketZip PC Card Dock enables USB-equipped PCs and Macs to read PocketZip PC Card drives. The PocketZip drive is also available in a customized version for the Compaq iPAQ Pocket PC.

The PocketZip drive is also built into some noncomputer devices, such as Agfa's ePhoto CL30 Clik! Digital camera, which uses the PocketZip disk instead of flash memory cards for its digital film, and Iomega's HipZip portable music player.

PocketZip Drive Performance and Size

The PocketZip PC Card drive has a maximum data transfer rate of 620KB/second, and the cartridges are approximately 2" square and about 3/4" thick, making PocketZip media very portable. Each PocketZip disk weighs about 1/3 of an ounce and costs about $10 per disk in quantity.

The high cost per MB and low capacity of the Iomega PocketZip media make, at first glance, a very poor comparison to other removable-media drives. But, no other removable-media drive is as compact, fitting into a Type II PC Card slot. The extremely small size of PocketZip and its capability to provide storage for a wide variety of computers and devices can balance off the high cost per MB of the media and drives for some users.

High-Capacity Floptical Drives

One of the first removable-media drives to break the 20MB barrier and maintain backward compatibility with standard 3 1/2-inch media was a drive made by a company called Insite Peripherals in the early 1990s. Their patented floptical technology used optical tracking to precisely align the magnetic read/write heads of the drive, which could store a then-amazing 21MB in the same form factor used by a 1.44MB 3 1/2-inch drive.

Although the Insite drive never became popular because of a combination of high drive and media cost and lack of BIOS support, it started several trends in high-capacity drive development, including backward compatibility with existing media, faster performance than ordinary floppy drives, and the combination of optical positioning and magnetic storage.

The performance specifications of the drive (average access time of 65ms, transfer rate of 1.6MB/sec, and rotational speed of 720rpm) are similar to those used by higher-capacity drives today. The Insite Peripherals floptical is a direct ancestor of the Imation LS-120 SuperDisk, which uses an advanced version of the same head-positioning techniques. Both the now-obsolete Insite floptical and the current Imation LS-120 are able to read, write, and format standard 3 1/2-inch 720KB and 1.44MB floppy disks, but the relatively unpopular 2.88MB floppy is not supported. The Imation LS-120 has survived challenges from other high-capacity, floppy-compatible products made by Sony (HiFD) and Caleb (UHD144/it) to be the only high-capacity drive that can also read and write standard 3 1/2-inch floppy media.

Floptical Drive Operation

The read/write heads of a floptical drive use magnetic recording technology—similar to that of floppy disk drives—and the floptical disk itself is composed of the same ferrite materials common to floppy and hard disks. Floptical drives are capable of such increased capacity because many more tracks are packed on each disk, compared with a standard 1.44MB floppy. Obviously, to fit so many tracks on the floptical disk, the tracks must be much narrower than those on a floppy disk.

That's where optical technology comes into play. Flopticals use a special optical mechanism to properly position the drive read/write heads over the data tracks on the disk. Servo information, which specifically defines the location of each track, is embedded in the disk during the manufacturing process. Each track of servo information is actually etched or stamped on the disk and is never disturbed during the recording process. Each time the floptical drive writes to the disk, the recording mechanism (including the read/write heads) is guided by a laser beam precisely into place by this servo information. When the floptical drive reads the encoded data, the laser uses this servo information again to guide the read/write heads precisely into place. The use of servo information is not unique to flopticals; hard drives have used servo tracks for years, but the use of a laser beam to read the servo tracks is what makes floptical drives unique.

LS-120 (120MB) SuperDisk Drives

The LS-120 drive (also called a SuperDisk drive) was designed to become the new standard floppy disk drive in the PC industry, replacing the venerable 3 1/2-inch 1.44MB floppy drive. LS-120 technology stores 120MB of data—or about 83 times more data than current 1.44MB floppy disks—and was developed by Imation; Compaq; Matsushita-Kotobuki Industries, Ltd. (MKE); and O.R. Technology. In addition to storing more, the newest models of drives read at up to 27 times the speed of standard floppy disk drives and write data up to 20 times faster than standard floppy disk drives when LS-120/ SuperDisk media is used. Figure 12.3 shows the media types that are compatible with the LS-120 drive.

Note

SuperDisk drives can use either SuperDisks or standard 3 1/2-inch floppies. Because the media sense hole and write-protect/enable slider are on opposite sides of the media, the SuperDisk is protected from damage if it is inserted into an ordinary floppy drive by mistake.

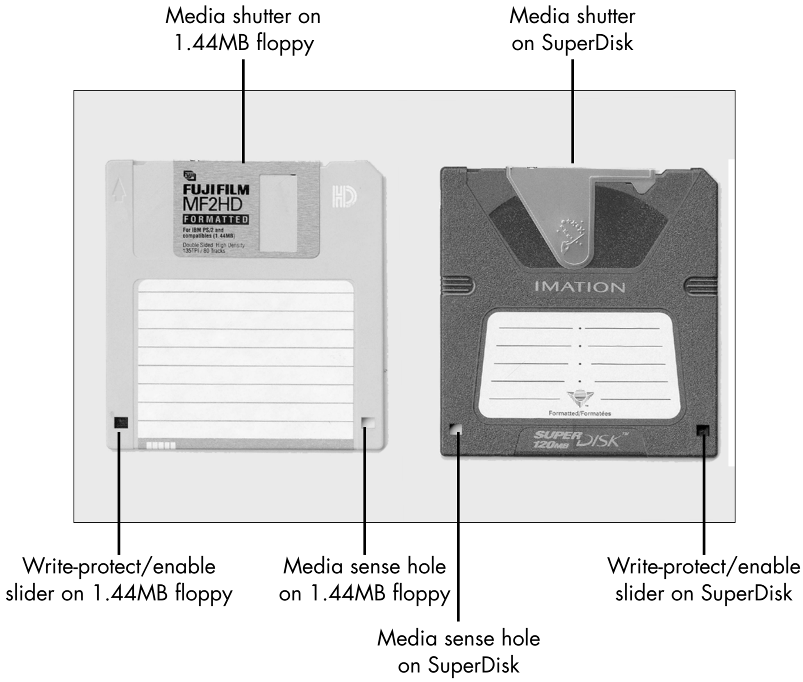

Figure 12.3 A standard 1.44MB 3 1/2-inch floppy disk (left) compared to LS-120 SuperDisk media (right).

The LS-120 floppy disk drive can act as the PC's bootable A: drive (in newer systems that support ATAPI removable devices; a few of the newest systems even support booting from USB drives) and is fully compatible with Windows NT, Windows 2000, and Windows 9x/Me. Windows XP supports the USB and ATAPI versions of the drive; check with vendors of PC Card and parallel-port versions for support and drivers. Macintoshes can also use USB-based SuperDisk drives, so data (and the drive itself) can be shared between PCs and Macs.

In addition to its own 120MB floppy disks, the LS-120 drive accepts standard 720KB and 1.44MB floppy disks and actually reads and writes those disks up to three times faster than standard floppy disk drives. By contrast, the rival Iomega Zip drives can't use existing floppy disks.

The most popular version of the LS-120 SuperDisk uses the standard IDE interface, which is available as an option for many new systems or can be added later. The most popular OEM supplier for the SuperDisk is Panasonic. USB and parallel versions also are available for an easy external connection, and PC Card (PCMCIA) and interchangeable drive-bay versions are available for notebook computers. The LS-120 provides a solution that not only replaces the existing floppy, but can even replace the floppy disk drive internally for virtually all purposes.

Note

The SmartDisk Corporation FlashPath flash-card adapters (covered later in this chapter) for 3 1/2-inch disk drives will not work in drives such as the LS-120 or PC Card-connected floppy drives; they are designed to work with standard 1.44MB 3 1/2-inch drives connected via a standard floppy controller only.

Having one of these high-capacity drives in a portable PC enables the use of relatively inexpensive 120MB removable disks while on the road. They are perfect for utility programs or databases and spreadsheets and can be removed and secured when the portable system is not in use.

LS-120 specifications are compared to standard 1.44MB floppy disks in Table 12.3; the following specifications reflect the revised versions of the LS-120 drive.

Note

In mid-1999, Imation redesigned the LS-120 drives to provide faster performance than the original version. Most models have now been upgraded, but Imation's PC Card model still uses the original mechanism, as seen in Table 12.3.

Table 12.3 Imation LS-120 Specifications Versus 1.44MB Floppy[1]

Drive type	LS-120	LS-120	LS-120	LS-120	3 1/2-inch floppy
Formatted capacity	120MB	120MB	120MB	120MB	1.44MB
Model (interface)	EIDE	USB	PC Card	Parallel	floppy cable
Maximum data transfer rate	1100KB/sec	750KB/sec	440KB/sec	750KB/sec	45KB/sec
Buffer size	10KB	10KB	8KB	10KB	none
Average seek time	60ms	60ms	70ms	60ms	84ms
Disk rotational speed	1440rpm	1440rpm	720rpm	1440rpm	300rpm
Track density	2,490tpi	2,490tpi	2,490tpi	2,490tpi	135tpi
Number of tracks	1,736× 2 sides	1,736× 2 sides	1,736× 2 sides	1,736× 2 sides	80× 2 sides

1. Third-party LS-120 drives might vary.

LS-120 SuperDisk Media

The LS-120 disk has the same shape and size as a standard 1.44MB 3 1/2-inch floppy disk; however, it uses a combination of magnetic and optical technology to enable greater capacity and performance. Named after the laser servo (LS) mechanism it employs, LS-120 technology places optical reference tracks on the disk that are read by a laser system. The optical sensor in the drive enables the read/write head to be precisely positioned over the magnetic data tracks, enabling track densities of 2,490tpi versus 135tpi for a 1.44MB floppy disk. Unlike phase-change, magneto-optical, or CD-R/CD-RW drives, the laser in the LS-120 drive is used strictly for positioning purposes.

Tip

For security-minded users, the LS-120 SuperDisk drives can use special LS-120 Secure Encryption media, which comes with software that enables data stored on the disks to be encrypted with the Blowfish algorithm, a powerful 64-bit block cipher first developed in 1993. Secure Encryption media costs about $16 each in quantities.

The LS-120 SuperDisk also can be used in the interchangeable drive bays of many high-end notebook computers. A pair of Panasonic digital cameras, the 1.3 megapixel PV-SD4090, and the 3.3 megapixel PV-SD5000 use SuperDisk media to store digital photos.

Many PC manufacturers provide the option of using an LS-120 drive in their products as standard equipment in place of the floppy drive. Besides coming in new systems, these drives also are available separately at a cost of about $75 or less in internal or external versions for upgrading older systems. The 120MB floppy disks are available for around $8.50–$10 per disk.

Other High-Capacity "Beyond Floppy" Drive Options

The LS-120 is the overwhelming favorite of users who want more than 100MB capacity and backward compatibility with ordinary 3 1/2-inch media. However, other drives have achieved the same capabilities. Sony's 200MB HiFD drive (also sold by IBM in an internal IDE/ATA form factor) and Caleb Technology's 144MB drive (which has been sold under the UHD144, it, and Monster Disk names) are capable of using standard 3 1/2-inch media as well as their proprietary high-capacity media. However, neither of these products is widely available and Caleb Technology (`www.calebstor.com`) went into Chapter 11 bankruptcy in May 2000. Because of the lack of available products and difficulties in obtaining media for existing drives, neither of these drives is recommended as a floppy replacement.

For more information about these drives, see *Upgrading and Repairing PCs, 12th Edition*, which is included in its entirety on the CD accompanying this book.

Hard-Disk–Sized Removable-Media Drives

The following drives have capacities of 1GB or larger and are fast enough to be considered removable-media hard drives. You can install an entire operating system and a major application on these cartridges and boot from it to completely customize your system's operation.

Jaz Drives

The Jaz drive from Iomega is a true removable-cartridge hard disk, available in 1GB and 2GB internal and external models. Unfortunately, the cartridges themselves cost $90–$100 each in quantity, making them much more expensive per GB than DAT or Travan backup tapes. The high cost of the media makes the Jaz drive unsuitable for backup when compared to traditional tape media, but it is possibly useful as an add-on external SCSI hard disk drive for either data or program files.

Figure 12.4 shows the 2GB external SCSI version of the Jaz drive. Jaz media is thicker and has a different shape from the media made for the lower-capacity Zip drives also produced by Iomega.

Figure 12.4 A 2GB external Jaz drive and media. *Photo courtesy of Iomega Corporation.*

Jaz drives are available in SCSI interface versions only; the 2GB model is backward compatible with 1GB media. Table 12.4 lists the specifications for Jaz drives.

Table 12.4 Jaz Specifications

Model	1GB	2GB
Formatted capacity	1070 million bytes	2000 million bytes
Transfer rate:		
Maximum	6.62MB/sec	8.7MB/sec
Average	5.4MB/sec	7.35MB/sec
Minimum	3.41MB/sec	3.41MB/sec
Burst	10MB/sec	20MB/sec
Average seek time read	10ms	10ms
Average seek time write	12ms	12ms
Access time	15.5ms–17.5ms	15.5ms–17.5ms
Disk rotational speed	5,400rpm	5,394rpm
Buffer size	256KB	512KB
Interface	Fast SCSI II	Ultra SCSI

Note

Some users of Jaz drives have also reported click-of-death problems similar to those experienced by Zip drive users. For more information, testing software, and solutions, see the Gibson Research Web site.

Castlewood Orb

The Castlewood Orb (see Figure 12.5) uses the same magneto-resistive (MR) technology used by many hard drives and achieves hard drive–like performance and capacity at a relative low cost per GB (2.2GB per cartridge at a cost of less than $30 per cartridge).

Figure 12.5 The external SCSI version of the Castlewood Orb drive comes with an HD-50 SCSI cable, an AC power pack, driver files on CD-ROM, one Orb disk with case, and a manual. As is typical with most SCSI drives, the SCSI host adapter is not included. *Photo courtesy of Castlewood Systems, Inc.*

The Orb is available in models supporting all leading interfaces, including EIDE, internal and external SCSI, parallel, and USB. Third-party vendors also have introduced IEEE-1394 versions of the Orb. Table 12.5 lists specifications for the various models made by Castlewood.

Table 12.5 Orb Specifications

Formatted capacity	2.2GB				
Average seek time read	11ms				
Average seek time write	12ms				
Disk rotational speed	5,400rpm				
Transfer rate by model:	EIDE	USB	Ext. SCSI[1]	Int. SCSI[2]	Parallel[3]
Maximum	12.2MB/sec	1.0MB/sec[3]	12.2MB/sec	12.2MB/sec	2MB/sec
Burst	16.6MB/sec	16.6MB/sec	20MB/sec	40MB/sec	40MB/sec

1. Ultra SCSI

2. Ultra Wide SCSI

3. Runs at maximum speed of interface; varies with device bus speed or number of drives on the USB port

Helping Your Orb Drive Run More Reliably

The price and performance of Orb drives and media makes them a promising alternative to other removable-media drives, but a large number of early adopters of the Orb have had problems. Some of the causes include

- Clashes between older Iomega and Orb drivers
- Not allowing the drive to initialize completely before using the drive

These problems led to a large number of drive and media failures when the drives were first released.

For more reliable operation, I recommend that you do the following:

- *Remove all Iomega drivers (Zip/Jaz tools, Guest, and so on) before installing the Orb and its drivers.* If you are using Iomega drives as well as the Orb, download the newest Iomega driver software and install it **after** you install the latest Orb software.
- *Download and install the latest Orb drivers for your operating system and firmware for your Orb drive model.* Check Castlewood's Web site (`http://www.castlewood.com`) for the latest information.
- *Allow the drive to spin up completely before using Windows Explorer or any other utility that views the drive's contents.*

Comparing Orb and Jaz Drives

Orb drives transfer data much more quickly than Jaz and are available in a wider variety of interfaces, including the easy-to-install and low-cost IDE internal model. Orb's cost per GB is 60% less than Jaz's.

Neither Orb nor Jaz media are produced by third-party vendors, so the drive manufacturer is the only source for media.

Note

In July 1999, Iomega sued Castlewood Systems for patent infringement; the lawsuit continues as of this writing. While none of Iomega's current product line uses a drive mechanism similar to the Orb's MR technology, Iomega also owns the intellectual property of the old SyQuest company. In addition, Castlewood was founded by a former SyQuest executive.

Iomega Peerless

The Iomega Peerless removable hard disk system was introduced at the January 2001 Consumer Electronics Show (CES) and MacWorld and should have hit store shelves in mid-2001.

Peerless features 10GB and 20GB removable hard disks, which integrate the read/write heads into a sealed case. This should eliminate head contamination, a frequent cause of removable-media drive failures in the past. The Peerless base station is a vertical mount enclosure about 4 inches wide and 5 inches tall and uses interchangeable interface modules. The first interface modules to be made available include the IEEE-1394 (FireWire) and USB 1.1 interface modules; USB 2.0 and SCSI versions will be introduced later. The base station contains the electronics for the drive system, which enables disks to be sold at very low costs.

The estimated transfer rate of the Peerless drive (when attached to the IEEE-1394 interface) is 15MBps.

"Orphan" Removable-Media Drives

Several recent removable-media drives have become "orphans" because of the closing of their manufacturers. This section discusses where you can get support for your "orphan" drives.

SyQuest Drives

Over the years, SyQuest has offered a wide variety of removable-media drives in capacities ranging from 44MB up to 1.5GB. They were very popular in the Macintosh world, but most SyQuest models were also made in PC versions. The last SyQuest models produced were the EzFlyer 230MB drive, the SparQ 1GB drive, and the SyJet 1.5GB drive. Parallel-port, IDE, and SCSI interface versions were produced, but the USB and IEEE-1394 interfaces were never supported.

From SyQuest to SYQT, Inc.

SyQuest filed a Chapter 11 petition with the United States Bankruptcy Court in Oakland, California on November 17, 1998. On January 13, 1999, SyQuest announced that it had entered into an agreement with Iomega Corporation to sell certain assets, including all its intellectual property, its U.S. inventory, and its U.S. fixed assets. Iomega *did not* take over support of SyQuest products.

SyQuest successor SYQT, Inc., offers limited sales and support operations. This includes online technical support via the World Wide Web, warranty returns, and product service operations. This means you can still purchase blank cartridges, buy drives, download drivers, and get repairs for most recent SyQuest products, but there will be no further development of the SyQuest "family" of products.

Even though SYQT, Inc. continues to sell and support SyQuest-brand drive products and media through the SYQT Web site, `http://www.syqt.com`. SyQuest products still qualify as "orphans" because there is no ongoing development of products. However, the Web site does now offer drivers for use with Windows 98, Windows Me, and Windows 2000, as well as drivers for older versions of Windows and MS-DOS on PC models from the old 44MB on up to the last models produced.

The SyQuest drives and media shown in Table 12.6 are supported by SYQT, Inc., and can be purchased from its Web site.

Table 12.6 Available SyQuest Drives and Media Quick Reference

Drive	Capacity	Media	Interface
SparQ	1GB	SparQ 1GB cartridge	Parallel; IDE
SyJet	1.5GB	SyJet 1.5GB cartridge	Parallel; IDE; SCSI (PC and Mac)
EzFlyer	230MB	EzFlyer 230MB cartridge; EZ135 135MB cartridge	IDE; SCSI (PC and Mac); Parallel

SYQT, Inc., provides driver and other technical support for these drives when used with Windows 95/98, Windows NT, Windows 2000, MS-DOS and Windows 3.1, and OS/2. SCSI drives are also supported on the Macintosh platform.

The SyQuest disks, like the Bernoulli cartridges, are easily distinguished from floppy disks. The 5 1/4-inch 44MB, 88MB, and 200MB cartridges used in some SyDOS drives are encased in clear plastic and are still available from SYQT, Inc.'s Web site. By contrast, the 3 1/2-inch SyJet 1.5GB and SparQ 1GB cartridges (also available from SYQT, Inc.) are an opaque black color.

The disks for the SyQuest and SyDOS drives are composed of a rigid platter inside a plastic cartridge but are not as well-protected as the disk in a Bernoulli cartridge. Some people consider these disks fragile. If the SyQuest and SyDOS cartridges are not severely jostled or dropped, they can be transported safely. However, these cartridges must be carefully protected when you mail or ship them.

According to SYQT technical support, most SyQuest and SyDOS cartridges can be left in the drive when powered down. However, SYQT recommends that cartridges for the 44MB and 88MB drives be removed before powering down the drive. With all drives, cartridges should be removed before transporting the drive.

Non-SYQT Support Sites

A third-party volunteer-staffed Web site you can also consult for technical support is `http://www.syquestsupport.com`; `windrivers.com` also has SyQuest drivers.

Avatar Shark Parts and Drivers

The Avatar Shark 250MB drive was a small removable-media drive that connected to the parallel port or PC Card slot of a PC. The Shark was built by Avatar Peripherals, which is now out of business.

Replacement cartridges, accessories, and drives can be purchased from Weymouth Technologies (`http://www.weymouthtech.com`), 119 Winthrop Lane, Holden, MA, 508-735-3513. Drivers and documentation for Windows 95/98, Windows NT, IBM OS/2, and MS-DOS can be downloaded from the Dead Boards link at `http://www.windrivers.com/company.htm`. A discussion forum is also available at this Web site.

Management Strategies for "Orphan" or Out-of-Production Drives

Because "orphan" drives have very small capacities, limited performance, and limited or no support by current and forthcoming operating systems, I recommend that you follow the strategy outlined here to help you move away from their use and toward up-to-date drives. Continuing to depend on an "orphan" can leave you stranded in the case of a drive or media failure. The following strategy is designed to help you protect your data (the most important part of any computer system!):

- Transfer all data on "orphan" drives to a current removable-media or optical-technology drive.
- Stop using the "orphan" drives for normal operations.

- Maintain a small inventory of the "orphan" drives in good working order if you provide services or perform data interchange with other users of these drives.
- Encourage suppliers and clients to start using currently available removable-media drives for data interchange.
- Determine which current drive or drives these other companies are using.
- Replace the "orphans" with drives that are compatible with the most popular media types used by your clients or business partners.

Removable Drive Letter Assignments

One problem people have when installing new drives is confusion with drive letter assignments. This becomes especially true when adding a new drive moves the assignments of previous drives, something that most people don't expect. Some simple rules govern drive letter assignments in Windows and DOS, which is discussed here.

All versions of Windows (as well as MS-DOS) treat floppy drives the same way, but major differences exist in the management of hard drives, CD-ROM/optical drives, and removable-media drives with Windows 9x/Me on the one hand and Windows NT 4.0, Windows 2000, and Windows XP on the other hand.

Floppy Drive Disk Assignments

With any version of MS-DOS or Windows, the system assigns the drive letter A to the first physical floppy drive. If a second physical floppy drive is present, it is assigned drive letter B. If no second floppy drive exists, the system automatically reserves B: as a logical drive representation of the same physical drive A:. This allows files to be copied from one disk to another by specifying `COPY file.ext A: B:`.

MS-DOS and Windows 9x/Me Disk Management

The basic rule with these operating systems is that devices supported by ROM BIOS–based drivers come first, and those assigned by disk-loaded drivers come second. Because floppy drives and hard drives are normally ROM BIOS–supported, these come first, before any other removable drives. After assigning A: and B: to floppy drives, the system then checks for installed hard drives and begins by assigning C: to the master partition on the first drive. **If you have only one hard disk,** any extended partitions on that drive are read, and any volumes in them are assigned consecutive letters after C:. For example, if you have a hard disk with a primary partition as C: and an extended partition divided into two logical volumes, they will be assigned D: and E:.

After the hard drive partitions and logical volumes are assigned, the system begins assigning letters to devices that are driver controlled, such as CD-ROM drives, PCMCIA attached devices, parallel port devices, SCSI devices, and so on. Here is how it works with only one hard drive split into three volumes, and a CD-ROM drive:

One drive primary partition	C:
One drive extended partition 1st volume	D:
One drive extended partition 2nd volume	E:
CD-ROM drive	F:

When a removable drive is added to the system proposed in the previous scenario, it is assigned either F: or G:, depending on the driver and when it is loaded. If the CD-ROM driver is loaded first, the removable drive is G:. If the removable drive driver is loaded first, it becomes F: and the CD-ROM drive is bumped to G:. In DOS, you control the driver load order by rearranging the `DEVICE=` statements in the `CONFIG.SYS` file. This doesn't work in Windows because Windows 9x, Me, NT, and 2000 use 32-bit drivers, which aren't loaded via `CONFIG.SYS`. You can exert control over the drive letters in Windows by manually assigning drive letters to the CD-ROM or removable drives. You do this as follows with Windows 9x and Windows Me:

1. Right-click My Computer, and select Properties.
2. Select the Device Manager tab.
3. Click the + next to the CD-ROM drive icon. Right-click the CD-ROM drive, select Properties, and select the Settings tab.
4. Select and change the Start Drive Letter.
5. Select the same letter for End Drive Letter.
6. Click OK, and allow your system to reboot for changes to take effect.
7. Repeat the previous steps by clicking the + next to Disk Drives, and assign a different drive letter to your removable drive.

Using these steps, you can interchange the removable drive with the CD-ROM drive, but you can't set either type to a drive letter below any of your existing floppy or hard drives.

So far, this seems just as everybody would expect, but from here forward is where it can get strange. The rule is that the system always assigns a drive letter to all primary partitions first and all logical volumes in extended partitions second. This means that if you have a second hard disk, it also can have primary and extended partitions, the extended partition can have two logical volumes, and the primary partition on the second drive could become D:, with the extended partition logical volumes becoming G: and H:.

Here is how it works with two hard drives, each split into three volumes, and a CD-ROM drive:

First drive primary partition	C:
Second drive primary partition	D:
First drive extended partition 1st volume	E:
First drive extended partition 2nd volume	F:
Second drive extended partition 1st volume	G:
Second drive extended partition 2nd volume	H:
CD-ROM drive	I:

In this example, if a removable drive were added, it would become either I: or J:. Using the same procedure outlined previously, you could swap I: or J: or assign them higher (but not lower) letters as well. Some factory-installed removable drives that use the IDE interface (such as some versions of the Zip 100 IDE) act like a second hard disk, rather than an add-on removable drive.

The utility software provided with the Iomega Zip and Jaz drives also can be used to assign the drive to any available drive letter.

To avoid scrambling existing hard drive letters when you install additional drives, prepare additional drives with extended partitions only. Drive letters in the extended partition on the second drive will follow the drive letters in the first drive's extended partitions and so forth if you install a third or even more hard drives. Here's what the result would be when you have two hard drives, with the first drive split up as a primary disk partition with two drives in an extended partition, and the second drive having no primary partition, but three logical drives in its extended partition:

First drive primary partition	C:
First drive extended partition 1st volume	D:
First drive extended partition 2nd volume	E:
Second drive extended partition 1st volume	F:
Second drive extended partition 2nd volume	G:
Second drive extended partition 3rd volume	H:

Drive Remapping Utilities

Although some utilities are available for remapping drive letters under Windows, I normally don't recommend them. This is because if you boot under DOS or via a floppy, these remappings are no longer in place and the standard BIOS mapping prevails. Because you might often boot to DOS to perform setup, diagnostics, configuration, or formatting/partitioning, confusion about which drive letters are what can lead to mistakes and lost data!

If you reset your CD-ROM or other removable-media drive to a different drive letter in Windows, be sure to set the drive to the same letter when you run the computer in command-prompt or MS-DOS mode. This is typically done through command-line options you can add to the `AUTOEXEC.BAT` statement for the drive. See your drive's instruction manual for details.

Windows NT 4.0, Windows 2000, and Windows XP Disk Management

Disk management for NT-based versions of Windows, including Windows NT 4.0, Windows 2000, and Windows XP (including XP Home Edition), offers many more options than in MS-DOS and Windows 9x/Me. The Disk Administrator tool is launched from the Drive properties Tools menu in Windows NT 4.0. The similar Disk Management tool is started from the Computer Management (Microsoft Management Console) utility in Windows 2000 and Windows XP. Both Disk Administrator and Disk Management can be used to control drive letters. To change a drive letter with either tool, right-click the drive and select Change Drive Letter and Path.

Although C: drive is assigned to the first hard drive by default in these versions of Windows, you can assign the drive letters you prefer to both CD-ROM/removable-media drives and to logical drives on a hard disk. By default, when additional hard-disk–based logical drives are added to a system, existing CD-ROM or other removable-media drive letters are not disturbed. Therefore, programs that depend on CD-ROM or removable-media drive paths continue to work.

You also can change the default boot drive letter from C: to another drive letter, but this is not recommended because it prevents your system from booting until manual Registry changes are made to correct the problem.

Comparing Price and Performance of Removable-Media Drives

Tables 12.7 and 12.8 compare the performance and price per MB of the best-performing (SCSI or EIDE) versions of the drives discussed in detail earlier in this chapter. The price per MB is calculated from the lowest cost per cartridge purchased in a multipack. Typical CD-R/CD-RW drives have been added to this comparison because many individuals might find these products a better choice for removable-media storage.

The tables are ranked in order by performance or cost per MB, from fastest/least expensive to slowest/most expensive.

Table 12.7 High-Capacity Removable-Media Magnetic Storage Drives Ranked by Performance and Compared with CD-R/CD-RW Drives

Drive	Capacity	Interface	Maximum Sustained Speed
Iomega Peerless	10GB	IEEE-1394	15MB/sec
Castlewood Orb	2.2GB	SCSI or EIDE	12.2MB/sec
Iomega Jaz 2GB	2GB	SCSI	8.7MB/sec
Typical 40x	700MB	SCSI or EIDE	6.0MB/sec
	CD-ROM Drive		
Typical 24x CD-ROM/CD-R/ CD-RW drive in playback mode	700MB	SCSI or EIDE	3.6MB/sec read
Typical 16X	700MB	SCSI or EIDE	2.4MB/sec
	CD-R Drive		
Iomega Zip 250	250MB	SCSI or EIDE	2.4MB/sec
Typical 12x CD-R drive	700MB	SCSI	1.8MB/sec write
Iomega Zip 100	100MB	EIDE	1.4MB/sec
Imation LS-120 SuperDisk	120MB	EIDE	1.1MB/sec
Typical 6x CD-R	650MB	EIDE	900KB/sec write
Iomega PocketZip	40MB	PC Card (n/a in EIDE)	620KB/sec
Typical 4x CD-RW (rewriteable) optical drive	Up to 650MB	EIDE	600KB/sec write

Figure 12.6 and Table 12.8 compare high-capacity SCSI-based drives with Zip, LS-120, and similar drives.

Table 12.8 High-Capacity Removable-Media Magnetic Storage Drives Ranked by Media Cost per MB and Compared with CD-R/CD-RW Drives

Drive	Capacity	Typical Media Cost in Quantities	Cost per MB
CD-R media (12x or faster speed)	700MB	$.40	Under 1 cent
CD-RW media (1x–4x speed)	650MB	$1.10	Under 1 cent
Castlewood Orb	2.2GB	$30	1.5 cents
Iomega Jaz 2GB	2GB	$80	3 cents
Iomega Peerless	20GB	$200	1 cent
Iomega Zip 250	250MB	$16	6.4 cents
Imation LS-120 SuperDisk	120MB	$10	8.3 cents
Iomega Zip 100	100MB	$9	9 cents
Iomega PocketZip	40MB	$10	23.8 cents

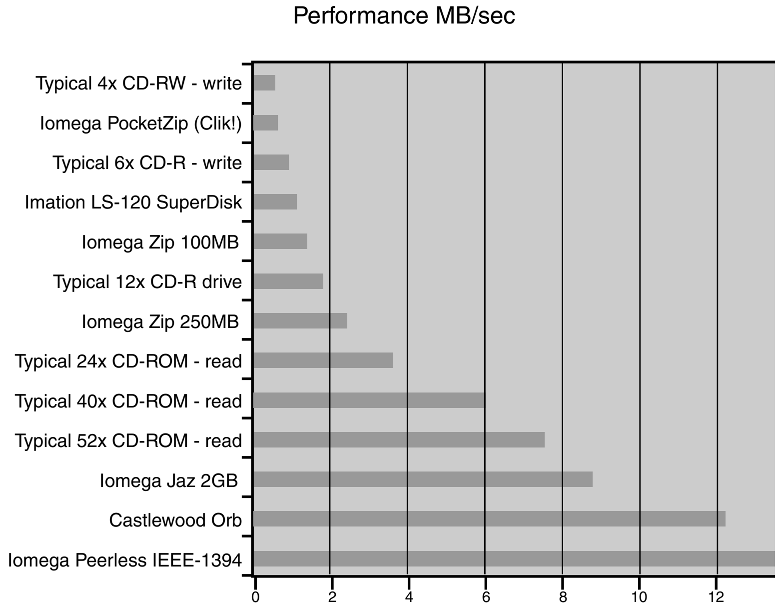

Figure 12.6 High-capacity SCSI or IEEE-1394–based drives, such as the Castlewood Orb, Iomega Jaz, and new Iomega Peerless, are as much as eight times faster than Zip, LS-120, or similar "large floppy" drives.

Figure 12.7 compares the cost per MB of CD-R/CD-RW media to the per MB cost of magnetic media.

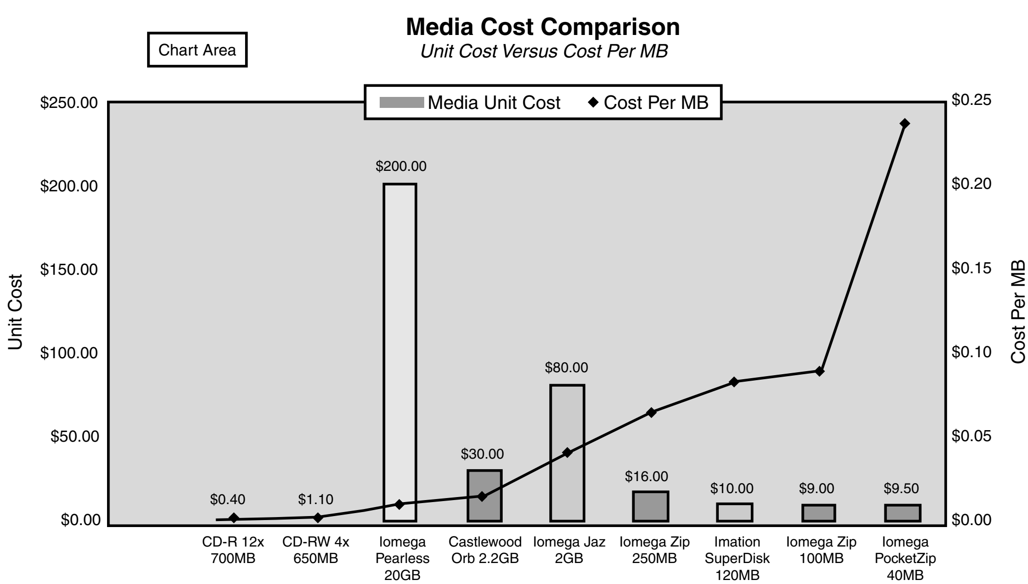

Figure 12.7 The cost per MB of recordable and rewriteable optical media, as well as the unit cost, is far lower than for magnetic media. The Iomega Peerless is the best value in magnetic media in cost per MB, whereas the Castlewood Orb is the best value in unit cost for greater than 1GB removable media. The least expensive media is the Iomega Zip 100, but it has the second-highest cost per MB.

As you can see from the previous comparisons, optical storage is substantially cheaper per MB than most magnetic removable-media drives, but the optical drive's write performance is substantially lower than many magnetic drives. For many users, the best strategy is to use magnetic storage for short-term use and projects in process and optical storage for near-archival storage and sending out finished information to other users.

When shopping for a removable drive, keep the following in mind:

- *Price per megabyte of storage.* Take the cost of the drive's cartridge or disk and divide it by the storage capacity to see how much you are paying per megabyte of storage. This difference in price becomes quite apparent as you buy more cartridges or disks for the drive. (Don't forget to factor in the cost of the drive itself if you are trying to decide which removable-media drive to buy!)
- *Access time versus need of access.* The access and data transfer speeds are important only if you need to access the data frequently or quickly. If your primary use is archiving data, a slower drive might be fine. However, if you plan to run programs off the drive, choose a faster drive instead.
- *Compatibility and portability.* Opt for an external SCSI, IEEE-1394, USB, or parallel port solution if you need to move the drive between various computers. USB is the lowest-cost and friendliest solution because it's built into recent systems and supports hot-swapping. Also verify that drivers are available for each type of machine and operating system you want to use with the drive, and consider whether you need to exchange disks with other users. The Iomega Zip disk and Imation LS-120 SuperDisk drives have become standards for removable-cartridge media. For some users, this might be the most important factor in choosing a drive.
- *Storage capacity.* For maximum safety and ease of use, the capacity of your storage device should be the largest available that meets your other requirements. Digital camera users, for example, will want the largest possible flash or disk storage supported by their cameras to allow more photos or higher-quality photos to be stored. Desktop and notebook computer users will want the largest drives possible for data backup or program storage.

Note

For one-time use, the CD-R drive is the best choice for two reasons: low media cost (well under $1 each in quantity) and near-universal compatibility (virtually all systems sold since the mid-1990s can read CD-R media in ordinary CD-ROM drives).

- *Internal versus external.* Most users find external parallel port or USB drives the easiest to install; additionally, they give you the option of using the drive on several systems. Internal drives are usually faster because of their IDE or SCSI interfaces and are more cleanly integrated into the system from a physical perspective.
- *Bootable or not.* The ATAPI/IDE version of the Imation LS-120 SuperDisk is BIOS supported in almost all new systems, and it is fully compatible with existing floppy drives. Therefore, the SuperDisk drive can completely replace the floppy, a decided advantage over Zip and the others. Although many recent systems can use the IDE Zip drive as a bootable drive, Zip drives are not compatible with standard 3 1/2-inch diskettes.

Magneto-Optical Drives

One of the most neglected types of removable-drive technologies is the magneto-optical (MO) drive. Introduced commercially in 1985, magneto-optical drives are now available in capacities exceeding 5GB, beating the size of the largest removable magnetic storage drives by a factor of about 2.5:1.

Two sizes of magneto-optical media and drives are available: 3 1/2-inch and 5 1/4-inch. The 3 1/2-inch drives have capacities up to 1.3GB, and the 5 1/4-inch drives have capacities that exceed 5GB. Originally, magneto-optical drives were strictly WORM (write-once, read many) drives that produced media that could be added to, but not erased. WORM drives are still on the market, but for desktop computer users, read/write MO drives are preferable.

Magneto-Optical Technology

At normal temperatures, the magnetic surface of an MO disk is very stable, with archival ratings of up to 30 years.

One surface of an MO disk faces a variable-power laser, whereas the other surface of the disk faces a magnet. Both the laser beam and the magnet are used to change the data on an MO disk. Figure 12.8 illustrates the magneto-optical writing and reading process.

The "optical" portion of an MO drive is the laser beam, which is used at high power during the erasing process to heat the destination area of the MO drive to a temperature of about 200° Celsius (the Curie point, at which a normally magnetic surface ceases to be magnetic). This enables any existing information in that area to be erased by a uniform magnetic field, which doesn't affect the other portions of the disk that are at normal temperature.

Next, the laser beam and magnetic field are used together to write information to the location by applying high power to the laser and applying a controlled magnetic signal to the media to change it to either a binary 0 or 1.

During the read process, the laser is used at low power to send neutrally polarized light to the surface of the MO disk. The areas of the MO disk that store binary 0s reflect light at a polarization angle different from those that store binary 1s. This difference of one degree is called the *Kerr effect*.

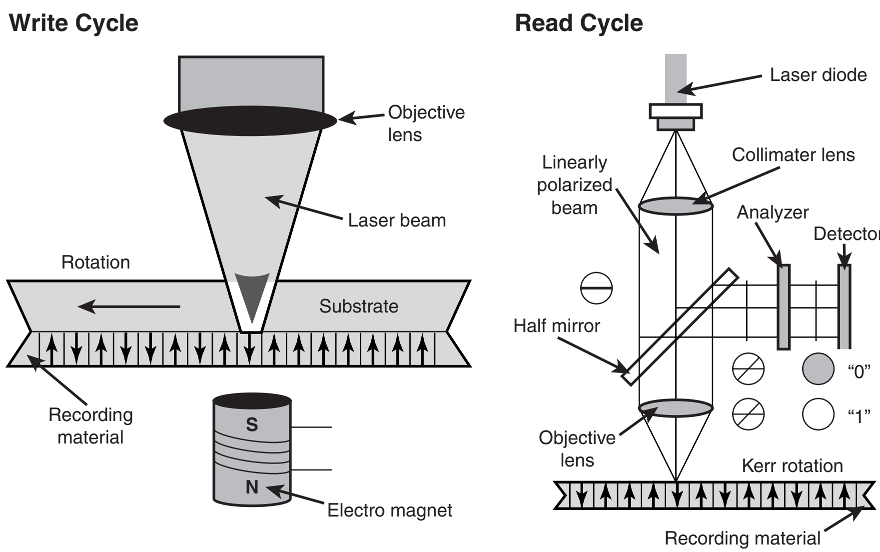

Figure 12.8 Magneto-optical drives use the laser at high power to heat the magnetic surface to enable its contents to be magnetically changed during the write cycle (left) and use the laser at low power to determine the angle of polarization (the Kerr effect) during the read cycle (right).

In older MO drives, the erase and write process involved two separate operations, but most recent MO drives starting with the Plasmon DW260 of 1997 use the LIMDOW method (light intensity modulated direct overwrite) for a single-pass operation with some media types. LIMDOW drives use magnets built into the disk itself, rather than separate magnets as in older MO drives. LIMDOW drives are fast enough to store MPEG-2 streaming video and make achieving higher capacities easier.

MO drives are available from many manufacturers at a variety of price points. The models listed in Table 12.9 are readily available from major computer retailers.

Table 12.9 Typical Magneto-Optical Drives and Media

Size	Example Drive and Interface	Max. Capacity and Other Usable Media	Performance	Approximate Drive Cost	Approximate Media Cost
3 1/2 inch	Fujitsu DynaMO 1300FE External IEEE-1394	1.3GB; can use 640MB, 540MB 230MB, and 128MB	5.9MB/sec maximum with 1/3GB (lower with smaller media)	around $400	around $35
5 1/4 inch	Sony SMO-F551/S Magneto-Optical Drive Internal SCSI	5.2GB; can use 4.8GB, 4.1GB, 2.6GB, and 2.3GB	5.07MB/sec read, 2.48MB/sec write (5.2GB media)	around $1,700	around $60

5 1/4-inch media MO drives are also available in external SCSI versions at slightly higher prices. ATAPI/IDE models are sold by some vendors, but aren't as easy to find.

Comparing MO to "Pure" Magnetic Media

Compared to most high-capacity removable-media drives, MO drive hardware is more expensive (especially in the 5 1/4 inch-media size), but media costs are far less per MB, durability is far better, and performance is as good or better than the 200MB-or-under class drives. The use of SCSI interfaces for most models was a drawback when MS-DOS/Windows 3.1 were the leading operating systems, but Windows 9x/Me/NT/2000/XP have much easier SCSI installation processes, and SCSI interfaces have dropped in price (and are included with some internal drives). If you can afford the high initial cost of the 5 1/4-inch–media MO drives, you'll have a fairly fast, durable, long-term storage solution that's also a good storage area for works in process.

Flash Card and Digital "Film"

The newest "hot" storage technology, flash memory, has really been around for several years as a main or an auxiliary storage medium for notebook computers. However, the rise of devices such as digital cameras and MP3 players has transformed this technology from a niche product into a mainstream must-have accessory.

How Flash Memory Works

Flash memory is a type of nonvolatile memory that is divided into blocks, rather than bytes as with normal RAM memory modules. Flash memory, which also is used in most recent computers for BIOS chips, is changed by a process known as Fowler-Nordheim tunneling. This process removes the charge from the floating gate associated with each memory cell. Flash memory then must be erased before it can be charged with new data.

The speed, low reprogramming current requirements, and compact size of recent flash memory devices have made flash memory a perfect counterpart for portable devices such as notebook computers and digital cameras, which often refer to flash memory devices as so-called "digital film." Unlike real film, digital film can be erased and reshot.

Types of Flash Memory Devices

Several types of flash memory devices are in common use today, and it's important to know which ones your digital camera is designed to use. The major types include

- CompactFlash
- SmartMedia
- ATA PC Cards (PCMCIA)
- MultiMediaCards
- Memory Stick

CompactFlash

CompactFlash was developed by SanDisk Corporation in 1994 and uses ATA architecture to emulate a disk drive; a CompactFlash device attached to a computer has a disk drive letter just like your other drives.

The original size was Type I (3.3mm thick); a newer Type II size (5mm thick) accommodates higher-capacity devices. Both CompactFlash cards are 1.433 inches wide by 1.685 inches long, and adapters allow them to be inserted into notebook computer PC Card slots. The CompactFlash Association (`http://www.compactflash.org`) is the organization that oversees development of the standard.

SmartMedia

Ironically, SmartMedia (originally known as SSFDC for solid state floppy disk card) is the simplest of any flash memory device; SmartMedia cards contain only flash memory on a card without any control circuits. This simplicity means that compatibility with different generations of SmartMedia cards can require manufacturer upgrades of SmartMedia-using devices. The Solid State Floppy Disk Forum (`http://www.ssfdc.or.jp/english`) oversees development of the SmartMedia standard.

MultiMediaCard

The MultiMediaCard (MMC) is the newest and smallest flash memory storage device designed for use in digital cameras and a wide variety of other devices, including smart phones, MP3 players, and digital camcorders. MMC was co-developed by SanDisk and Infineon Technologies AG (formerly Siemens AG) in November 1997. The MMC uses a simple 7-pin serial interface to devices and contains low-voltage flash memory. A proposed Secure MultiMediaCard might be developed to provide flash memory storage for copyrighted digital music. The MultiMediaCard Association (`www.mmca.org`) was founded in 1998 to promote the MMC standard and aid development of new products.

Sony Memory Stick

Sony, which is heavily involved in both notebook computers and a wide variety of digital cameras and camcorder products, has its own version of flash memory, known as the Sony Memory Stick. These devices feature the unique erase-protection switch, which prevents accidental erasure of your photographs. Sony has also licensed Memory Stick technology to other companies, such as Lexar Media.

ATA-Compliant PC Card

Although the PC Card (PCMCIA) form factor is now used for everything from game adapters to modems, from SCSI interfacing to network cards, its original use was computer memory, as the old PCMCIA (Personal Computer Memory Card International Association) acronym indicated.

Unlike normal RAM modules, PC Card memory acts like a disk drive, using the PCMCIA ATA (AT Attachment) standard. PC Cards come in three thicknesses (Type I is 3.3mm, Type II is 5mm, and Type III is 10.5mm), but all are 3.3 inches long by 2.13 inches wide. Type I and Type II cards are used for ATA-compliant flash memory and the newest ATA-compliant hard disks. Type III cards are used for older ATA-compliant hard disks; a Type III slot also can be used as two Type II slots.

Comparing Flash Memory Devices

As with any storage issue, you must compare each product's features to your needs. You should check the following issues before purchasing flash memory devices:

- *Which flash memory products does your camera or other device support?* Although adapters allow some interchange of the various types of flash memory devices, for best results, you should stick with the flash memory type your device was designed to use.
- *Which capacities does your device support?* Flash memory devices are available in ever-increasing capacities, but not every device can handle the higher-capacity devices. Check the device and flash memory card's Web sites for compatibility information.
- *Are some flash memory devices better than others?* Some manufacturers have added improvements to the basic requirements for the flash memory device. For example, Lexar, maker of CompactFlash+, makes two series of faster-than-normal cards (the 4x and 8x series) and also produces some models that can be attached to USB ports for fast data transfer using a simple USB cable rather than an expensive and bulky card reader.

Table 12.10 compares the major types of flash memory devices. Devices are listed in alphabetical order.

Table 12.10 Major Flash Memory Devices Compared

Flash Memory Device	Maximum Capacity	Interface
ATA DataFlash	2GB	PC Card Type II
CompactFlash	160MB	Proprietary
Memory Stick	64MB	Proprietary
MultiMediaCard	128MB	Proprietary
SmartMedia	128MB	Proprietary

Only the ATA DataFlash cards can be attached directly to a notebook computer's PC Card slots. All other devices need some type of adapter to transfer data. Figure 12.9 shows how CompactFlash, Memory Stick, MultiMediaCards, and SmartMedia compare in size to each other.

Moving Flash Memory Devices from Camera to Computer

Several types of devices can be purchased to enable the data on flash memory cards to be moved from digital cameras and other devices to a computer. Although some digital cameras come with an RS-232 serial cable for data downloading, this is a painfully slow method, even for low-end cameras with less than a megapixel (1,000 pixel horizontal width) resolution.

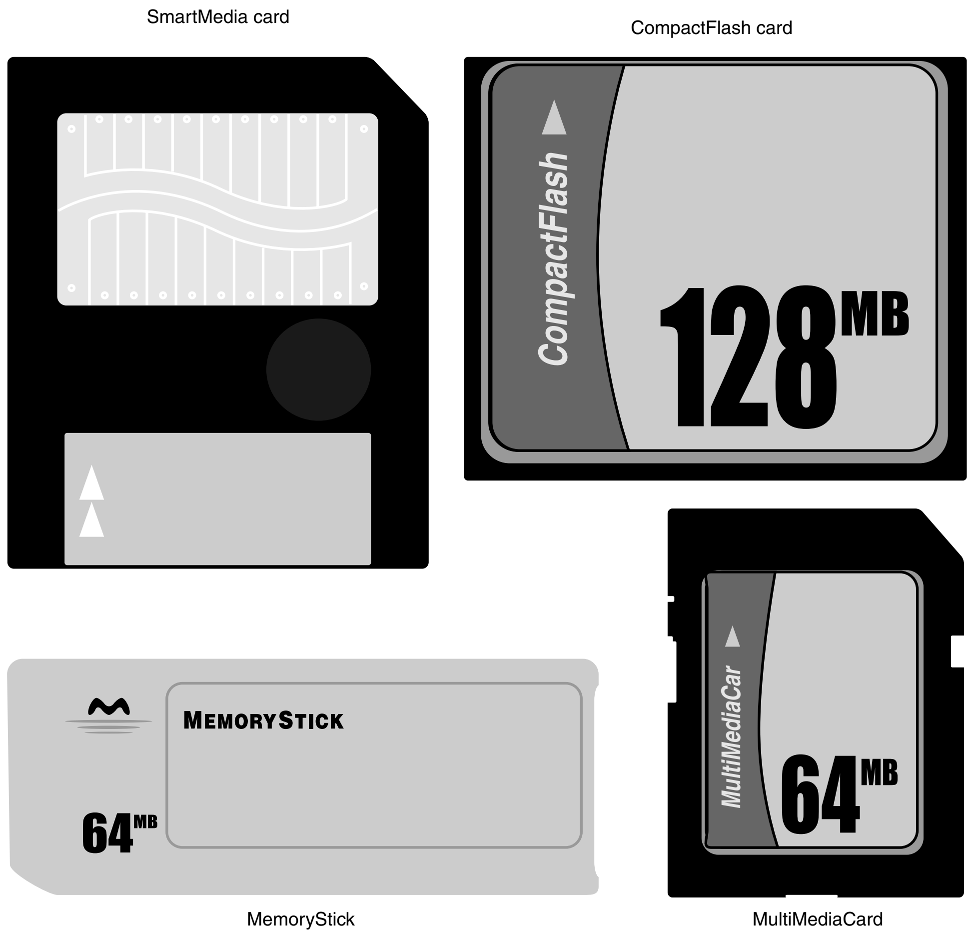

Figure 12.9 SmartMedia, CompactFlash, Memory Stick, and MultiMediaCard flash memory devices.

Card Readers

The major companies who produce flash card products sell card readers that can be used to transfer data from proprietary flash memory cards to PCs. These card readers typically plug into the computer's USB ports (some older versions might use the parallel port) for fast access to the data on the card.

In addition to providing fast data transfer, card readers enable the reuse of expensive digital film after the photos are copied from the camera.

The major benefit to external card readers is that they can be used with either notebook or desktop computers. Figure 12.10 shows a typical card reader with a CompactFlash memory card inserted.

Type II PC Card Adapters

For use in the field, you might prefer to adapt flash memory cards to the Type II PC Card slot. You insert the flash memory into the adapter; then, you slide the adapter into the notebook computer's

Type II PC Card slot. Figure 12.11 shows how a CompactFlash card Type II PC Card adapter works. As with card readers, check with the major companies who produce your type of flash memory device for the models available.

Figure 12.10 A SanDisk CompactFlash card reader. *Photo courtesy of SanDisk.*

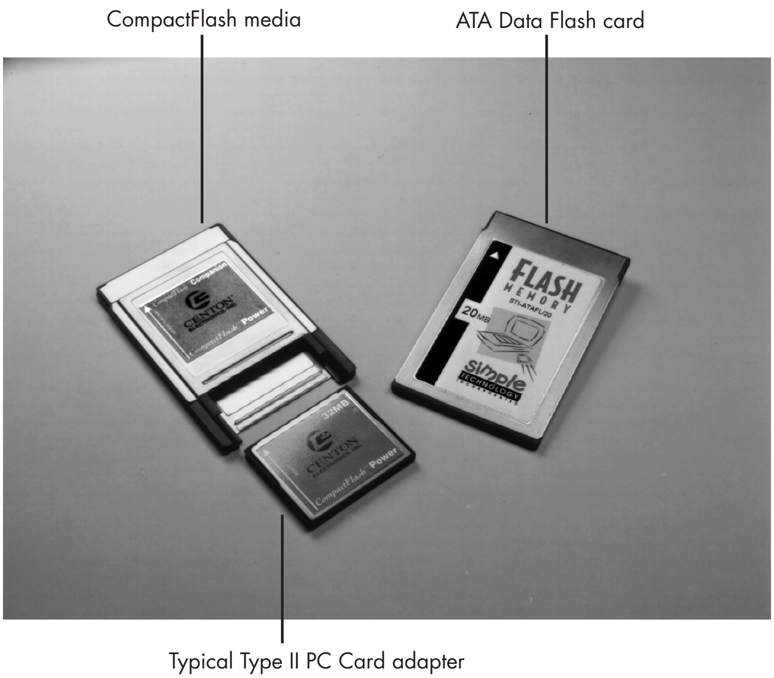

Figure 12.11 A typical Type II PC Card adapter for CompactFlash media (left) compared to an ATA DataFlash card (right).

Floppy Adapters

If you have a standard 3 1/2-inch floppy drive connected to a standard floppy controller, you have a third alternative for reading the contents of flash memory cards: SmartDisk (`http://www.smartdisk.com`) makes the FlashPath line of flash memory card adapters that fit in place of a 3 1/2-inch floppy disk. Separate models are available for SmartMedia, Sony Memory Stick, and CompactFlash cards. As shown in Figure 12.12, the flash memory devices are inserted into the FlashPath adapter. Then, the FlashPath adapter is inserted into a 3 1/2-inch floppy drive.

Figure 12.12 A CompactFlash module is inserted into the FlashPath adapter; the assembly is then inserted into a standard 3 1/2-inch floppy drive. *Photo courtesy of SanDisk.*

Microdrive Technology

If you prefer magnetic storage for digital camera data storage, consider the IBM Microdrive, which is sold by IBM and various other companies under OEM agreements.

The IBM Microdrive comes in four capacities (170MB, 340MB, 512MB, and 1GB) and can be used with several digital cameras, many notebook computers, and other devices. The Microdrive is a true hard drive at 1" wide and works in CompactFlash+ Type II slots, enabling it to be a direct replacement for standard CompactFlash memory cards on compatible equipment. IBM also offers the Microdrive as part of a Travel Kit containing a PC Card adapter, and the drive is compatible with many standard CompactFlash card readers. See the `www.storage.ibm.com` Web site for more information about Microdrive products, a compatibility matrix, and other information. Figure 12.13 shows how a Microdrive's mechanism compares in size to a standard U.S. quarter (25-cent piece).

Figure 12.13 A U.S. quarter (left) is just slightly smaller than the IBM Microdrive (right). *Courtesy of International Business Machines Corporation. Unauthorized use not permitted.*

Now that the IBM Microdrive is being sold by Iomega as part of its big push into CompactFlash-compatible storage devices, this amazing drive might become better known and more popular than ever. Iomega's version of the Microdrive includes a PC Card adapter for use with notebook computers and QuickSync 2 backup software, Adobe ActiveShare photo album software, and the Music Match JukeBox Plus digital music player.

Tape Drives

The data backup and archive needs of a personal computer can be overwhelming. People with large hard drives and numerous applications installed and those who generate a large amount of data might need to back up their computers on a weekly or even a daily basis.

In addition, a critical need on today's PCs is data storage space. Sometimes it seems as though the storage requirements of a PC can never be satisfied. On nearly any PC used for business, study, or even fun, the amount of software installed can quickly overwhelm even a large hard drive. To save space on the primary storage devices, you can archive infrequently used data to another storage medium.

Historically, a popular method for backing up full hard disks or modified files has been a tape backup drive. This section focuses on current tape backup drive technologies to help you determine whether this type of storage technology is right for you.

Tape backup drives are the most simple and efficient device for creating a full backup of your hard disk if the tape is large enough. With a tape backup drive installed in your computer, you insert a tape into the drive, start your backup software, and select the drive and files you want to back up. The backup software copies your selected files onto the tape while you attend to other business. Later, when you need to retrieve some or all of the files on the backup tape, you insert the tape in the drive, start your backup program, and select the files you want to restore. The tape backup drive takes care of the rest of the job.

This section examines the various types of tape backup drives on the market, describing the capacities of different drives as well as the system requirements for installation and use of a tape drive. The following topics are covered in this section:

- Hard-disk–based alternatives to tape backup
- Advantages and disadvantages to tape backup
- Common standards for tape backup drives
- Common backup tape capacities
- Newer higher-capacity tape drives
- Common tape drive interfaces
- Portable tape drives
- Tape backup software

Hard-Disk–Based Alternatives to Tape Backup

Before you decide to adopt a tape backup as your backup strategy, keep the following alternatives in mind.

The high capacity and low cost per MB of the new Iomega Peerless drive system might make this appealing for both primary and backup storage. Conventional hard disks also can be used for backups if both the original drive and an identical drive are connected to a mirroring RAID (redundant array of inexpensive drives) array. RAID arrays were once strictly for SCSI drives on networks because of their high cost. However, recent developments in high-performance, low-cost RAID-compatible IDE/ATA host adapters on motherboards and incorporated into add-on cards make this another useful backup strategy to consider.

Disadvantages of Tape Backup Drives

Many computer users who once used tape backups for data backup purposes have turned to other technologies for the following reasons:

- *Creating a tape backup copy of files or of a drive requires the use of a special backup program in almost all cases*. A few tape drives allow drive letter access to at least part of the tape capacity, but this feature is far from universal.
- *Retrieving data from most tape backup drives requires that the data files be restored to the hard disk*. Other types of backup storage can be treated as a drive letter for direct use from the media.
- *Tape backups store and retrieve data sequentially*. The last file backed up can't be accessed until the rest of the tape is read; other types of backup storage use random access, which enables any file on the device to be located and used in mere seconds.
- *Tape backups can be cantankerous*. The magnetic tape used can be easily erased or can stretch out of shape, destroying the data onboard; other types of backup storage are more durable.
- *Low-cost tape backups using QIC (Quarter Inch Committee), QIC-Wide, or Travan technology once had little problem keeping up with increases in hard disk capacity and once sold for prices comparable to or less than the hard disks they protected*. Today's hard disks have capacities of 20 to 40GB and are far less expensive than most comparably sized tape backups.
- *Newer backup and restore techniques, such as drive imaging/ghosting, rival the ease of use of tape back-ups and permit data restoration with lower-cost optical storage devices such as CD-R drives*.

For these reasons, the once-unassailable position of a tape backup drive as being the must-have data protection accessory is no longer a secure one; plenty of rivals to tape backups are on the market. However, if you can afford a high-quality DDS or AIT tape drive, you can get a high-performance and high-reliability solution because these same drives are used in the demanding roles of network backup.

Advantages to Tape Backup Drives

Although tape backup drives are no longer the one-size-fits-all panacea for all types of bigger-than-floppy storage problems, they have their place in keeping your data safe. Following are several good reasons for using tape backup drives:

- *Tape backups are a true one-cartridge backup process for individual client PCs, standalone computers, or network servers when high-capacity tape drives and cartridges are used.*
- *If you or your company has made previous backup tapes, you must keep a tape drive to access that data or to perform a restore from it.* Tape backup drives are needed if you need to restore from previously made backup tapes.
- *If you want an easy media rotation method for preserving multiple full-system backups, tape backup drives are a good choice.*

Common Tape Backup Standards

Several tape backup standards exist for individual client PC and small server tape backup drives:

- *QIC, QIC-Wide, and Travan.* These are three branches of a large and diverse family of low-cost, entry-level tape backup drives that can handle data up to 20GB at 2:1 compression.
- *DAT (Digital Audio Tape).* This is a newer technology than QIC and its offshoots, using Digital Data Storage (DDS) technology to store data up to 40GB at 2:1 compression. DAT drives are often referred to as DDS drives for this reason.
- *AIT (Advanced Intelligent Tape).* This is becoming the successor to DAT/DDS because it can handle higher capacities than DAT.
- *OnStream's ADR (Advanced Digital Recording).* This features a capacity up to 50GB at 2:1 compression and a choice of SCSI, IDE, and popular external interfaces in its 30GB (2:1 compression) version for desktop computers.
- *Ecrix's VXA drives.* These offer a capacity of 66GB at 2:1 compression and a variety of high-speed SCSI and IEEE-1394 interface options. The VXA-1 format has been approved by the ECMA, an important international organization that establishes standards for information and communication systems.

Other tape backup standards, such as DLT (Digital Linear Tape) and 8mm, are used primarily with larger network file servers and are beyond the scope of this book.

QIC and Its Variants (QIC-Wide and Travan)

The first quarter-inch tape drive was introduced in 1972 by 3M, and it used a cartridge size of 6×4×5/8 inches. This pioneering cartridge established the so-called "DC" data cartridge standard that was used with the first true QIC-standard drive—the 60MB QIC-02, introduced in 1983–84. The QIC-02–compatible drives were sold for several years and, like many early tape backup drives, used a dedicated host adapter board. QIC-02's small capacity began to be a problem in the mid-1980s, and many other QIC standards were created for larger drives.

The QIC (`http://www.qic.org`) has introduced more than 120 standards over the years in both the older DC and newer minicartridge (MC) forms. This huge number of standards has actually led to a fragmented marketplace that makes it increasingly difficult to determine the backward compatibility and cross-compatibility factors that QIC, ironically, was established to provide.

This section focuses on the recent and current versions of the minicartridge versions of QIC and related technologies, such as QIC-Wide and Travan.

Note

For more information on older QIC standards, see Chapter 12 of *Upgrading and Repairing PCs, 11th Edition*, and Chapter 12 of *Upgrading and Repairing PCs, 12th Edition*, found in their entirety on the CD-ROM accompanying this book.

QIC Tapes and Head Recording Technologies

QIC-standard backup tapes are magnetic media, primarily ferric oxide, and are recorded in a manner similar to the way data is encoded on your hard drive, using either Modified Frequency Modulation (MFM) or Run-Length Limited (RLL) technology.

QIC and related technologies use a simple linear recording head mechanism, similar to the way that cassette tapes are recorded and erased. Different QIC standards use different types of tape and record different numbers of tracks to reach specified capacities.

The most common QIC MC standards used in recent years are listed in Table 12.11. Although new drives no longer use QIC cartridges as their primary backup technology, backward compatibility with popular sizes you might have used in the past is an important consideration when you purchase a new tape drive. For economy, some drives allow you to use less expensive QIC media for day-to-day backups of changed files only and larger QIC-Wide or Travan cartridges for full backups. Generally, recent tape drives maintain read compatibility with several older tape standards but support a very limited number of tape standards for write compatibility.

Internal versions of the QIC MC tape backup drives in Table 12.11 were connected to the floppy controller, either in place of the B: drive or by using a special piggyback cable that enables two floppy drives plus the tape backup to function on a single floppy controller. External versions could connect to the parallel port.

The QIC-40 and QIC-80 cartridges must be formatted before use; some tape vendors have sold both formatted and unformatted versions of these cartridges. Because formatting even a short tape can take more than an hour, you should buy preformatted tapes. Later QIC cartridge versions always are preformatted at the factory.

Table 12.11 Popular QIC MC Standards

Standard/Cartridge	Size/2:1 Compression	Interface
QIC-40/DC-2000	40MB/80MB	Floppy
QIC-40/DC-2060	60MB/120MB	Floppy
QIC-80/MC-2120	125MB/250MB	Floppy, parallel port
QIC-80XL/MC-2120XL	170MB/340MB	Floppy, parallel port
QIC-3020XL/MC-3020XL	680MB/1.36GB	Floppy, parallel port, IDE

As you can see from Table 12.11, QIC drives have fallen behind the hard drive developments of the late 1990s. Because the safest and best way to back up a hard disk with tape is to use a single tape, a solution to the QIC storage “crisis” was necessary.

Increased QIC and Travan Performance

Because of the fragmented nature of the QIC MC standards and the need to increase storage capacity as drive size increased, several approaches have been used to help QIC grow to meet the needs of larger, faster hard disks and systems:

- Longer data cartridges
- QIC-Wide tapes and drives
- Travan tapes and drives

Longer Data Cartridges

The tape length in normal QIC-80 (MC-2120) cartridges is 300 feet, allowing only 125MB of uncompressed data to be stored on a single tape using drives such as the HP/Colorado Jumbo 250. The MC-2120XL extended the tape length to 425 feet, enabling up to 170MB of uncompressed data to be stored.

This same approach has been taken to its logical conclusion by Verbatim, which offers its QIC Xtra EX-series cartridges for a variety of popular QIC standards, as seen in Table 12.12.

Table 12.12 Standard and QIC Xtra Tape Cartridges and Capacities

Standard/Cartridge	Capacity/ 2:1 Compression	QIC Xtra Replacement	Capacity/ 2:1 Compression
QIC-80/MC2120	125MB/250MB	DC 2120Extra	400MB/800MB
QIC-3020XL/MC3020XL	680MB/1.36GB	MC 3020Extra	1.6GB/3.2GB

Verbatim also makes EX-series cartridges compatible with some of the Travan series drives. A major advantage of the Verbatim EX series is that QIC, QIC-Wide, and Travan drives can all use the same tape (depending on model), enabling a single cartridge to be used for several tape drives. If you are unable to replace your older tape drives with higher-capacity models, the Verbatim Xtra series can provide your existing units with significantly higher capacity.

Figure 12.14 compares a normal QIC minicartridge to the Verbatim Xtra series.

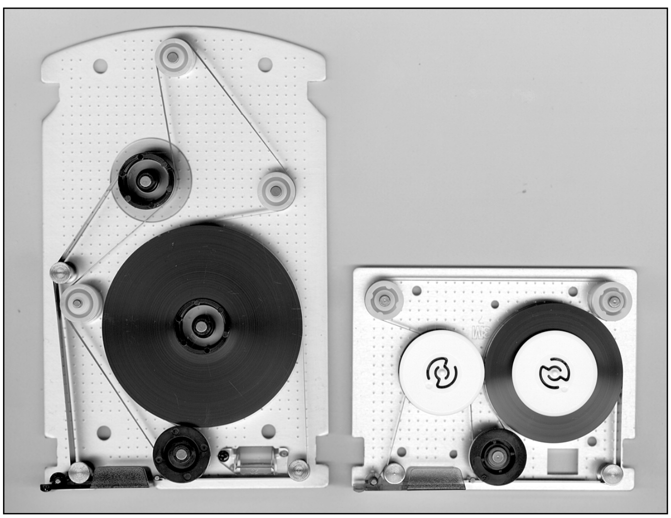

Figure 12.14 A Verbatim DC2120-EX (QIC-80) tape cartridge (left) holds 1,000 feet of tape, compared to the standard DC-2120 tape cartridge's 307 feet of tape (right), and provides more than three times the storage per cartridge in this size. The Verbatim Xtra cartridge also uses internal stabilizers for the larger tape spool, not shown in this photo.

QIC-Wide Drives and Media

Sony developed its proprietary QIC-Wide drives and media to provide a growth path for QIC MC tape drive users. The name, QIC-Wide, is amusing because a QIC-Wide tape isn't a quarter-inch wide; the tape contained in a QIC-Wide cartridge is 8mm, or .315 inches wide. The "wider than QIC" tape allows QIC-Wide cartridges to hold more data per foot than the QIC standard on which each cartridge is based. Although Sony's QIC-Wide drives are no longer on the market, the wider tape and backward compatibility with QIC standards have provided the inspiration for Travan drives—many of which can use QIC-Wide cartridges as an alternative to their native Travan media.

Table 12.13 lists common QIC-Wide cartridges and their capacities, along with the QIC MC standard the cartridge is based on for backward compatibility.

Table 12.13 QIC-Wide Cartridges and Capacities

QIC-Wide Cartridge	Capacity/2:1 Compression	Based on QIC Standard
QW5122F	208MB/410MB	QIC-80
QW3000XL	1GB/2GB	QIC-3000
QW3010XLF	450MB/900MB	QIC-3010
QW3020XLF	849MB/1.6GB	QIC-3020
QW2GB[1]	1GB/2GB	N/A
QW3080XLF	2GB/4GB	QIC-3080
QW3095XLF	2GB/4GB	QIC-3095
QW3210XLF	2.3GB/4.6GB	QIC-3210

1. This is the same cartridge used by the Iomega Ditto 2GB drive.

Travan Cartridge Tape

The successor to both QIC-MC and QIC-Wide drives was created in 1994 by 3M (now Imation). Travan drives maintain backward compatibility with various QIC standards and provide backup capabilities up to 10GB uncompressed and 20GB at 2:1 compression.

The Travan platform features a unique drive/minicartridge interface patented by Imation. The Travan platform fits in a 3 1/2-inch form factor, enabling easy installation in a variety of systems and enclosures. Travan drives can accept current QIC, QIC-Wide, and Travan minicartridges—a critical need for users, given the installed base of more than 200 million QIC-compatible minicartridges worldwide.

Currently, several levels of Travan cartridges and drives are available, each based on a particular QIC standard. Table 12.14 lists the currently available Travan cartridges and capacities. All Travan cartridges use .315 inch (8mm) wide tape.

Table 12.14 Travan Family Cartridges and Capacities

Travan Cartridge (Previous Name)	Capacity/ 2:1 Compression	Read/Write Compatible with	Read Compatible with
Travan-1 (TR-1)	400MB/800MB	QIC-80, QW5122	QIC-40
Travan-3 (TR-3)	1.6GB/3.2GB	TR-2, QIC-3020, QIC-3010, QW-3020XLW, QW-3010XLW	QIC-80, QW-5122, TR-1

Table 12.14 Continued

Travan Cartridge (Previous Name)	Capacity/ 2:1 Compression	Read/Write Compatible with	Read Compatible with
Travan 8GB (Travan 4/TR-4)	4GB/8GB	QIC-3095	QIC-3020, QIC-3010, QIC-80, QW-5122, TR-3, TR-1
Travan NS-8[1]	4GB/8GB		QIC-3020, QIC-3010, QIC-80
Travan NS-20	10GB/20GB		Travan 8GB, QIC-3095

1. *This cartridge can be used in place of the Travan 8GB (TR-4); the same cartridge can be used on either NS8 or TR-4 drives.*

Note

Backward compatibility can vary with drive; consult the manufacturer before purchasing any drive to verify backward-compatibility issues.

Most Travan drives on the market today use the Network Series (NS) technology described in the following section. At one time, an NS-36 standard (36GB compressed) was planned, but it appears that the NS-20 is the end of the line for the Travan technology.

The Travan NS

Drives that support Travan NS technology are designed to solve two problems that have plagued tape backup users for many years: data compression and data verification.

On QIC-40 and above, QIC-Wide, and standard Travan drives, data compression is performed by the backup software used by the drive. This could cause the following problems:

- Drives might have difficulty reading data if different backup software were used to make the backup and perform the restoration.
- The speed of the computer had a major impact on how fast backups could be performed; a typical backup program (such as Iomega's Ditto Tools) would offer three settings: no compression, compress to save time, and compress to save space, forcing the user to choose between maximum data storage and maximum speed.

On the same drives, backup software supports a verification step, which compares the data written to the tape with the data on the drive. Unfortunately, this requires that the tape be rewound to the beginning of the current backup and be read to the end while the hard disk is also read. The result? A backup that took 45 minutes without verification would take more than 90 minutes with verification enabled. This inefficient write-rewind-reread process has discouraged many users from relying on this safer backup method. Also, errors caused by changes in the state of a Windows 9x computer (such as screensavers being enabled or swapfiles changing in size) during the time passage between backup and verify tended to create the erroneous notion that the backup wasn't accurate.

Travan NS–compatible drives use a dual-head design (see Figure 12.15) that enables data to be verified as soon as it is written (read-while-write). They also feature hardware data compression, which allows a higher data capacity (up to 20GB at 2:1 compression). The result is faster and more reliable backups. The Travan NS20 cartridges also use a different metal media formula for greater data density than older Travan drives do.

Currently, Travan NS8 and NS20-based drives are sold primarily by Seagate Technologies, Tecmar Technologies, and Tandberg Data.

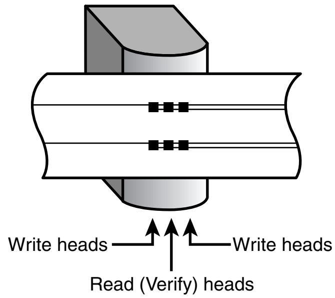

Figure 12.15 Travan NS tape drives use separate read and write heads to enable data to be verified as soon as it is written, saving the time-consuming rewind and verify operation used with QIC, QIC-Wide, and earlier Travan drives.

Proprietary Versions of Travan Technology

Ironically, because Travan technology was designed to bring an end to the QIC MC—QIC-Wide tape "wars," some drives use proprietary versions of the Travan standard. Nonstandard sizes include

- 5GB Tecmar/Iomega DittoMax
- 5GB HP/Colorado
- 6.6GB AIWA Bolt
- 7GB Tecmar/Iomega DittoMax
- 10GB Tecmar DittoMax
- 14GB HP/Colorado

The drive manufacturer is the principal supplier of media for some of these drives, whereas others are also supported with third-party media. Consult the drive manufacturers' Web sites for details.

OnStream ADR Technology

OnStream was founded in February 1998 as a spin-off from Philips Electronics, and its CEO, William T. Beierwaltes, had previously founded low-cost backup leader Colorado Memory Systems (now the HP/Colorado division of Hewlett-Packard).

Although the future of OnStream was uncertain after the liquidation of OnStream's U.S. operations (OnStream, Inc.) in March 2001, a new company—OnStream Data B.V.—based in the Netherlands, immediately took over sales, support, and development of OnStream drives and technology. The U.S. operations of the new OnStream Data company are located in Austin, TX. OnStream-compatible ADR tape cartridges are available from Verbatim in both 30GB and 50GB capacities, as well as from OnStream Data.

Introduced in 1999, OnStream's ADR (advanced digital recording) technology tape drives are designed to answer many of the limitations and complaints that users have had about traditional tape backup solutions.

◀◀ See "Disadvantages of Tape Backup Drives," p. 669.

Features of ADR

ADR uses a multiple-track linear recording system that reads and writes eight tracks at once, enabling read-while-write verify for speed and reliability and a relatively low tape travel speed to minimize wear (and noise!). ADR also uses several other techniques to foster additional reliability:

- Embedded servo information keeps the read/write heads aligned with the tracks at all times.
- ECC (error correction code) recording applied over all eight tracks (spatially distributed) allows reliable data recovery even if an entire track is destroyed.
- Continuously variable tape-travel speeds enable the drive to adjust to the different speeds of data flow from the hard drive without slowing down the entire tape backup process; as the data transfer rate increases, the drive runs faster, and the drive slows down as the data-transfer rate decreases.
- Single-pass media defect mapping allows reliable recording without rewinding the tape for a separate verify pass.

User Benefits of ADR

Several benefits to ADR are as follows:

- *ADR drives can be treated as a drive letter when used with the included Echo software.* This includes drag-and-drop file transfer and direct use of the tape's contents without a restore step (including viewing full-motion video and listening to MP3s).
- *Quiet backups.* These result from the multiple-track recording feature and variable-speed motor.
- *Background "set it and forget it" backup operation at reduced speed or fast dedicated backup of large hard drives in just an hour or two.*
- *Low cost per MB for both drives and media.*
- *Reliable data backup and online storage in a single device.* The claimed reliability for ADR-technology media exceeds the reliability of both other tape-backup systems and hard drives.

ADR Technical Specifications

Table 12.15 lists the technical specifications for OnStream's line of ADR drives, available in IDE, various flavors of SCSI, parallel, and USB interfaces. Drives for Macintosh only and drives bundled with third-party backup programs are also available but are not listed. All drives listed are supplied with OnStream's Echo software.

Media retail is $40 for the 30GB cartridge in a single pack and $60 for the 50GB cartridge in a single pack. Multiple-cartridges packs are available at a reduced price.

OnStream is the only producer of ADR drives at this writing. The ADR recording process is illustrated in Figure 12.16 (as compared to the DAT helical recording process).

Table 12.15 OnStream ADR Family Specifications for Windows PCs

Drive Model	Interface	Performance	Retail	Media Used
DI30	IDE ATAPI	1–2MB/sec	$299	ADR 30GB
DP30	Parallel	.7–1.4MB/sec	$399	ADR 30GB
USB30	USB	.85–1.7MB/sec	$399	ADR 30GB
SC30	SCSI internal	2–4MB/sec	$499	ADR 30GB
SC30	SCSI external	2–4MB/sec	$599	ADR 30GB
SC50	SCSI internal	2–4MB/sec	$699	ADR 50GB or 30GB
ADR50 Int	LVD SCSI internal	4–8MB/sec	$799	ADR 50GB or 30GB
ADR50 Ext	LVD SCSI external	4–8MB/sec	$949	ADR 50GB or 30GB

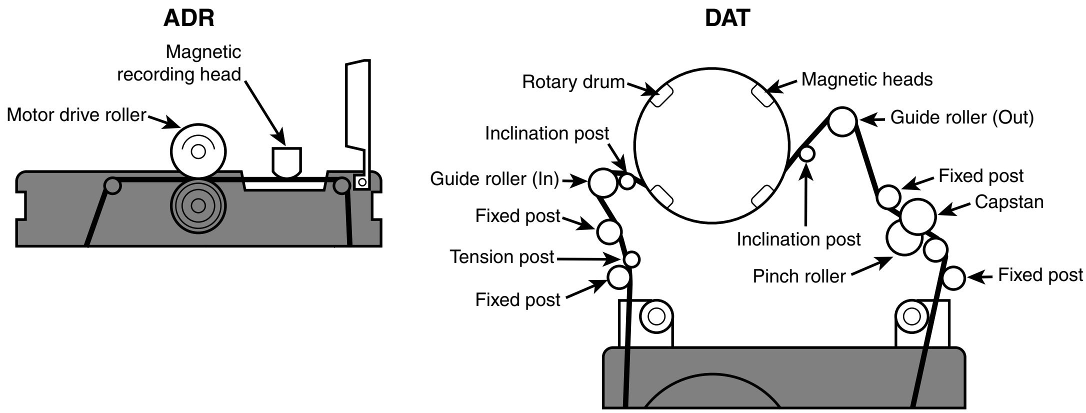

Figure 12.16 ADR drives use a multitrack linear recording mechanism (left), whereas DAT drives use a helical scan recording head that resembles the mechanism in a VCR (right). Both methods greatly increase data density compared to QIC-family drives, but helical scan recording exposes more of the tape to potential contamination.

OnStream Data also makes an external IEEE-1394 version of its 30GB (2:1 compression) drive but offers it for only the Macintosh platform.

DAT/DDS, AIT, and Other High-Capacity Tape Drive Standards

With the abandonment of Travan capacities beyond 20GB compressed, users of today's high-capacity hard drives must turn to larger tape backup standards. In addition to the OnStream ADR, the same tape backup standards long supported by workstation and large network servers can also be used with today's versions of Windows for both individual desktop computers and small network servers. Additionally, new high-capacity technologies are available to support today's larger drives.

4mm digital audio tape (DAT/DSS), 8mm videotape, 8mm AIT, digital linear tape, scalable linear recording (SLR), and Ecrix VXA are the major choices available for users who need higher-capacity backups. An emerging choice for very high-capacity (100GB and up) drives is the Ultrium version of the LTO Technology standard. All these technologies are available in autoloading tape libraries suitable for large networks, as well as single-cartridge drives intended for small network servers or desktop use.

Proprietary Versus Open Standards

If you want a wider variety of choices in drives, media, and pricing, you might prefer to purchase a high-performance drive type that is made by several companies. However, some of the most advanced technologies are controlled by a single vendor.

Drive technologies available from multiple vendors include

- *DAT/DDS.* Introduced and licensed by Sony to numerous manufacturers
- *AIT.* Introduced and licensed by Sony to numerous manufacturers
- *DLT.* Originally developed by Digital Equipment Corporation, but was purchased by Quantum in 1994
- *LTO (Linear Tape-Open).* Developed by HP, IBM, and Seagate

The following drive technologies are sold by a single vendor:

- *SLR*. Tandberg Data
- *VXA*. Ecrix

However, third-party vendors might sell tape cartridges compatible with even so-called "proprietary" standards.

DAT/DDS Tape Drives

Of the many high-performance tape drives on the market, this author's favorite is the DAT/DDS tape drive family because of its combination of performance, capacity, reliability, and reasonable price. Four levels of DAT/DDS drive capacity are available:

- *DDS-1*. This entry-level member of the family (2GB/4GB at 2:1 compression) is now obsolete.
- *DDS-2*. Has the same capacity as drives based on Travan NS8 (4GB/8GB at 2:1 compression).
- *DDS-3*. Has a slightly larger capacity (12GB/24GB at 2:1 compression) than Travan NS20.
- *DDS-4*. The largest member of the DAT/DDS family, it has a 20GB/40GB at 2:1 compression capacity, which is double the capacity of Travan NS20.

Even though DAT/DDS drives are more expensive than Travan drives with similar capacities, the media cost is much lower because of the drive's design. For example, you will pay about three times as much for a Travan NS20 cartridge as for a slightly higher-capacity DDS-3 cartridge. A DDS-4 cartridge, which offers double the capacity of Travan NS20, still sells for about 30% less. DDS drives are more reliable than Travan or earlier QIC-based drives, which is a vital consideration because the most important reason to use a tape backup is to perform a restore. The enhanced reliability of DDS drives is aided by the inclusion of automatic head-cleaning features built into most DDS drives and media.

Helical Scan Recording on DAT, 8mm, and AIT Drives

Exabyte 8mm, Sony DAT/DDS, and Sony AIT use helical scan recording. The read/write heads used in helical scan recording are mounted on a drum and write data at a slight angle to the tape, using a mechanism highly reminiscent of that in a VCR (refer to Figure 12.16). The entire surface of the tape is used to store data, enabling more data to be placed in a given length of tape than with the linear recording techniques used by the QIC family of drives.

AIT Unique Features

Sony's AIT has several unique features designed to make backup and restoration faster and more reliable. An optional Memory In Cassette (MIC) chip allows the cartridge to remember which of the 256 on-tape partitions were used for the data you want to restore, so the correct starting point can be located in seconds. AIT drives also have a servo tracking system called Auto Tracking Following (ATF), which is used for accurate data-track writing, and Advanced Lossless Data Compression (ALDC), a mainframe-style compression method that can compress data to a greater extent than other methods. The drives also feature built-in head cleaning that is activated when soft (correctable) errors reach a preset limit, metal-evaporated tape media that avoids head contamination, and a 3 1/2-inch form factor.

DLT Unique Features

DLT segments the tape into parallel horizontal tracks and records data by streaming the tape across a single stationary head at 100–150 inches/sec during read/write operations. This is a dramatic contrast to traditional helical-scan technology, in which the data is recorded in diagonal stripes with a rotating drumhead while a much slower tape motor draws the media past the recording head.

The result is a very durable drive and a robust medium. DLT drive heads have a minimum life expectancy of 15,000 hours under worst-case temperature and humidity conditions, and the tapes have a life expectancy of 500,000 passes.

SLR Unique Features

Tandberg's SLR drives use a linear recording method; the tape used by the SLR 40, SLR 60, and SLR 100 is divided into 192 tracks. Twenty-four prewritten servo tracks are used to adjust the position of the read/write head as necessary. This feature is designed to ensure compatibility of SLR tapes between drives, enabling a tape written by one drive unit to be readable by another unit. Six tracks are written at the same time. The entry-level SLR7 uses a simplified recording method that uses two tracks. Both tape types have fault tolerance features that enable the drive to switch to another track for data recording if the original track fails.

Ecrix VXA Unique Features

The Ecrix VXA drives combine a special recording and special playback method. The recording method used somewhat resembles a normal helical scan, but the tape is guided past the magnetic drum with a completely different type of mechanism and the data is recorded at variable speeds that change according to how fast the host can transmit data. This eliminates the need to wind tape backward because of data underruns (back-hitching). Data is recorded in 64-byte groups of 387 data packets rather than in linear blocks. VXA drives use a special read feature called overscan operation (OSO). OSO performs redundant reads of each group of data packets, enabling data to be retrievable even from damaged tapes. The packetizing of data works the same way as on the Internet: Data can be read in any order and reassembled into its original form when all packets are received. In tests, Ecrix has boiled, frozen, and even poured hot coffee over VXA tapes and been able to retrieve 100% of the stored data.

LTO Technology Unique Features

Linear Tape-Open, better known as LTO, is a very high-performance tape backup technology that offers two distinct types of mechanisms:

- *Ultrium*. This implementation of LTO is optimized for very high capacity. For example, Ultrium drives have an uncompressed capacity of 100GB (200GB at 2:1 compression). They also have special features such as dynamic powerdown (protects tapes from damage during a power interruption), intelligent data compression, intelligent media analysis to avoid suspect tape areas, and variable tape speed to minimize back-hitching (moving the tape backward because of a data underrun). Ultrium drives are popular in both single-drive and tape-library formats, although they are quite expensive: Basic single-cartridge units start at just under $5,000.
- *Accelis*. This implementation of LTO is optimized for very high speed, using a dual-reel cartridge that enables tape to be loaded from the mid-point instead of the beginning. It has a native capacity of 25GB (50GB at 2:1 compression). Accelis also features cartridge memory (used to retrieve data about the cartridge's previous use to make locating data faster) and throughput of 20MB–40MB per second. Accelis appears to be an on-paper variation at this point, with no drives on the market using this variation on LTO.

Comparing High-Performance Tape Backup Technologies

As the preceding sections indicate, you have many choices in large, high-performance tape backup. All the drive technologies discussed in this section use various SCSI interface versions and can be purchased as internal or external drives. Even though they are more expensive than Travan or OnStream ADR drives, they offer the capacities needed by today's larger hard drives.

Unlike the confusing backward-compatibility picture for QIC-family drives, the more advanced drives in each family are backward compatible with smaller drives.

Table 12.16 summarizes the performance and other characteristics of these tape technologies and compares them to Travan NS8 and NS20 drives and OnStream ADR. The price of the tape drives varies tremendously depending on which version of SCSI is selected, whether the drive is internal or external, and whether a single-tape or tape-library drive is selected. The standards shown in Table 12.17 are listed in order by native capacity. All drive interfaces are SCSI, except as noted. Maximum prices listed are for the most expensive single-drive SCSI interface model except as noted; most models of a given drive will be cheaper, depending on the SCSI version supported, whether the drive is sold bare or as a kit, and whether it is internal (less expensive) or external.

Table 12.16 High-Performance Tape Backup Standards Compared

Drive Type	Capacity/2:1 Compressed	Backup Speed (Native/Compressed)	Drive Price Range	Media Cost
DAT DDS-2	4GB/8GB	.5–1.1MB/sec	under $1,000	under $10
Travan NS8	4GB/8GB	.6–1.2MB/sec	under $500	under $35
SLR5	4GB/8GB	.38–.56MB/sec	under $600	around $40
Exabyte 8mm (Eliant 820)	7GB/14GB	1–2MB/sec	under $1,600	around $10
Travan NS20	10GB/20GB	1–2MB/sec	under $500	under $40
DAT DDS-3	12GB/24GB	1.1–2.2MB/sec	under $1,000	around $15
Exabyte 8mm (Mammoth-LT)	14GB/28GB	2–4MB/sec	under $1,600	around $40
ADR 30GB	15GB/30GB	1–2MB/sec IDE 2–4MB/sec SCSI	under $300 under $600	around $40
SCSIDAT DDS-4	20GB/40GB	2–4.8MB/sec	under $1,500	under $40
Exabyte 8mm (Mammoth)	20GB/40GB	3–6MB/sec	under $2,700	around $60
SLR7	20GB/40GB	3–6MB/sec	under $1,000	around $50
DLT 4000	20GB/40GB	1.5–3MB/sec	under $2,000	around $70
SLR50	25GB/50GB	2–4MB/sec	around $2,300	around $90
VXA-1	33GB/66GB	3–6MB/sec	under $1,200	around $80 (33/66GB); around $50 (20/40GB); around $30 (12/24GB)
AIT-1	25GB/50GB or 35GB/70GB	3–6MB/sec	under $2,600	around $70
DLT 7000	35GB/70GB	5–10MB/sec	under $4,300	around $80
ADR 50GB	25GB/50GB	2–4MB/sec SCSI 4–8MB/sec LVD SCSI	under $950	$60
AIT-2 SLR	50GB/100GB	6–12MB/sec	under $3,900	around $100

From Table 12.16, you can see that the Travan NS8 and NS20 drives are among the least expensive SCSI-based drives to purchase, but the cost per MB for media is much lower with DAT/DDS drives. The performance is higher with all 20GB and up drives of other types. For an individual computer or small network server, the ADR50, DDS-3, DDS-4, SLR7, and VXA-1 drive families represent the best balance of initial cost, performance, and media cost per MB. DLT, Exabyte 8mm, and AIT drives are better choices for larger network server backup, especially if purchased in their more expensive tape-library forms (not listed).

Note

To learn more about DAT, DLT, and Exabyte 8mm tape drives, see *Upgrading and Repairing PCs, 11th Edition*, which is included in printable PDF format on the CD accompanying this book.

Choosing a Tape Backup Drive

Choosing a tape backup drive can be a simple job if you need to back up a single standalone system with a relatively small hard drive. The decision becomes more complex if the system has a larger hard drive or if you must back up not only a desktop system but also a laptop. Choosing a tape backup drive type can be an even more complex program if you must back up a network server's hard drives and perhaps even back up the workstations from the server. As you ponder which backup tape drive type you should select, consider the following factors:

- The amount of data you must back up
- The interfaces your equipment supports
- The data throughput you need
- The tape standard that is best for your needs
- The cost of the drive and tapes
- The capabilities and compatibility of the included driver and backup software

By balancing the considerations of price, capacity, throughput, compatibility, and tape standard, you can find a tape drive that best meets your needs.

Note

When purchasing a tape backup drive, take the time to look through magazines in which dealers or distributors advertise. Several publications specialize in PCs and carry advertising from many hardware and software distributors. I recommend publications such as the *Computer Reseller News* and *Computer Shopper*. *Computer Shopper's* online shopping service can help you locate multiple sources for both popular and rare items quickly.

These publications cater to people or companies willing to go around the middlemen and buy direct. By reading such publications, you can get an excellent idea of the drives available and the price you can expect to pay.

While reading about drive capabilities and prices, don't neglect to read reviews of the software included with each drive. Verify that the software capabilities match your expectations and needs. This is especially important if you intend to use the drive on a non–Windows 9x system because most backup software today is tailored for Windows 9x.

Capacity

The first rule for selecting a tape backup drive is to buy a drive with a capacity large enough for your needs, both now and for the foreseeable future. The ideal is to buy a drive with enough capacity so you can start your backup software, insert a blank tape in the drive, walk away from the system, and find the backup completed when you return. Because tape backups are generally rated by their maximum (2:1 compression) capacities—which is seldom reached in practice—you should calculate the "true" size of a tape backup drive by multiplying the native (noncompressed) capacity of a drive by 1.5 (equal to rating the drive as 1.5:1 compression). Thus, a so-called "20GB" tape backup might be better described as having a "15GB" capacity (10GB uncompressed times 1.5).

You should always ensure that your tape backup medium supports a capacity larger than your largest single drive or partition. This makes automated backups possible because you won't have to change a tape in the middle of a backup. And, even if you don't mind replacing tapes in the middle of a backup, a single-tape backup is safer. If the first tape of a multiple-tape backup is damaged or lost, the entire backup is unusable with most backup systems!

Tape Standards and Compatibility

The next most important consideration, after adequate capacity, is choosing a drive whose tapes meet a standard that is useful to you. If you have existing tapes you want to restore, or you receive tapes from other users that you must read, you need a drive that can work with those tapes. Use the backward-compatibility information listed earlier to help you decide on a drive to purchase if this feature is important to you.

If your ability to work with older tape media is only an occasional issue, you might prefer to buy a high-performance drive for current backups and maintain an older drive that matches the older standard. Most Travan-type and QIC-Wide drives can read QIC-80 tape cartridges, for example.

Tip

It is important that you make a choice you can live with. If you manage a large installation of computers, mixing QIC, Travan, DAT, and 8mm drives among systems is seldom a good idea.

Software Compatibility

Equally important to your consideration is the software required to operate each drive. Currently, most parallel port and IDE drives come with software that runs under the Windows 9x operating system. SCSI tape drives usually also support Windows NT, Windows 2000/XP, or Unix. USB-based drives are primarily designed for Windows 98/Me/2000/XP, although Windows 2000/XP might not support as many devices as Windows 9x/Me does. Check the manufacturers' Web sites for operating-system compliance if your office's computers use more than one operating system.

Most operating systems have their own software for backing up data to a tape drive. If you intend to use this software, you should verify that the drive you purchase is supported by each piece of software on each system you intend to use with the drive. Third-party programs usually offer more features, but you might need to buy separate programs for the various operating systems your office uses.

Data Throughput

Any of the IDE or SCSI interface drives covered earlier should provide adequate performance (1MB/sec or above when backing up compressed data), but performance suffers if you opt for the convenience of USB or parallel port drives.

Floppy-interface QIC, QIC-Wide, and Travan drives should be considered obsolete for large-drive backups because of the limitations of the floppy interface and their small capacities.

Cost

You can figure the cost per MB for a drive in two ways: media cost only (which is valid for users with an existing drive) or drive plus media costs (which is a better method for new purchasers). Regardless of your favorite choice(s) in removable storage, be sure to look at the total picture, taking into account the savings from multipack data and the benefits of the extra speed of SCSI and IDE.

Tip

One point worth remembering when you evaluate whether to buy a tape drive is that the cost of the tapes and drive, taken as a whole, is nowhere near as high as the costs (in terms of frustration and lost productivity) of a single data-damaging hard drive problem. Considering that most people are more likely to back up a system if they have a tape drive installed than if they must use another medium for the backup, the cost of a drive and tapes is quite small, even on a standalone PC used mostly for fun.

Tape Drive Installation

Because most tape drives today use the same IDE, SCSI, USB, or parallel-port connection options that are used by other types of storage devices, you should see the appropriate sections of this book for more details about these devices:

- Chapter 14, "Physical Drive Installation and Configuration," provides detailed instructions for installing hard drives, floppy drives, and CD drives.
- Chapter 7 provides exhaustive coverage of the IDE interface.
- Chapter 8 provides detailed coverage of the SCSI interface.
- Chapter 16 provides information on USB and serial interfaces.

Note

For more details about installing the older floppy-interface tape backup drives, see *Upgrading and Repairing PCs, 11th Edition*, available in printable PDF format on the CD included with this book.

Tape Drive Backup Software

The most important decision you can make after you choose the tape standard and capacity of your backup tape drive is the backup software you will use with it.

The three sources for tape backup software are

- Software bundled with the drive
- Software bundled with the operating system
- Software obtainable from third parties

Use the following checklist to evaluate the software you plan to use with your tape backup drive:

- *Device support.* You might prefer to use tape for most backups, but can you change your mind and use high-capacity removable magnetic or optical storage if you need to? Some backup software bundled with a particular drive will work only with that drive; check whether a full version with more options is available.
- *Compatibility with existing backups.* If you have replaced an older tape drive with a new one, can the backup software as well as the tape drive read your old data?
- *Adjustable compression options.* If you are using a drive without hardware data compression, you should be able to adjust the compression methods used, or even turn them off to make sending the tape to the user of another drive easier.
- *Data safety options.* In addition to verify, good tape software should also include some form of ECC error correction to make recovering the data in case of media damage easier.

- *Disaster recovery.* Many bundled or operating system–standard backup programs require you to reinstall the operating system before you can restore the contents of a crashed drive. Insist on a disaster recovery feature that will allow you to restore a drive from bootable disks and the tape backup without taking the time to reinstall the operating system first.

Other useful features to look for include

- *Unattended backup scheduling.* Enables you to schedule a backup for a time when you won't need to use your computer
- *Macro capability.* Use when selecting options and the files to back up
- *A quick tape-erase capability.* Use when erasing the entire contents of a tape
- *Partial tape-erase capability.* Use when erasing only part of a tape
- *Tape unerase capability.* Use when recovering erased data
- *Password-protect capability.* Enables you to protect backup data from access by unauthorized persons

Read reviews, check compatibility, look for trial versions, and be sure to test the backup and restore features as you look for the best tape backup program for your needs.

Tip

Backup software vendor Novastor (`www.novastor.com`) has a unique solution for a major problem caused by moving from an older backup system to a new one: What to do with the data on the older tapes? Its Tape Copy software enables you to move data archives from your outmoded SCSI or IDE tape backup to a new SCSI- or IDE-based backup system. If you have extensive backup data and don't want to retain your old tape backup drive, Tape Copy might be the answer.

Tape Drive Troubleshooting

Tape drives can be troublesome to install and operate. Any type of removable media is more susceptible to problems or damage, and tape is no exception. This section lists some common problems and resolutions. After each problem or symptom is a list of troubleshooting steps.

Can't Detect the Drive

- For parallel port drives, use the tape backup as the only device on the drive and check the IEEE-1284 (EPP or ECP) mode required by the drive against the parallel port configuration.
- For USB drives, be sure you're using Windows 98 or higher and that the USB port is enabled in the BIOS; many systems originally shipped with Windows 95 have this port disabled.
- For IDE drives, ensure that the master/slave jumpers on both drives are set properly.
- For SCSI drives, check termination and Device ID numbers.
- For external drives of any type, ensure that the drive is turned on a few seconds before starting the system. If not, you might be able to use the Windows 9x Device Manager to Refresh the list of devices, but if this doesn't work, you must restart the computer.

Backup or Restore Operation Failure

If your tape drive suffers a backup or restore operation failure, follow these steps:

1. Make sure you are using the correct type of tape cartridge.
2. Remove and replace the cartridge.

3. Restart the system.
4. Retension the tape.
5. Try a new tape.
6. Clean the tape heads.
7. Make sure all cables are securely connected.
8. Rerun the confidence test that checks data-transfer speed with a blank tape (this test overwrites any data already on the tape).

Bad Block or Other Tape Media Errors

To troubleshoot bad block or other types of media errors, follow these steps:

1. Retension the tape.
2. Clean the heads.
3. Try a new tape.
4. Restart the system.
5. Try initializing the tape.
6. Perform a secure erase on the tape (previous data will no longer be retrievable from the tape).

Caution

Note that most minicartridge tapes are preformatted and can't be reformatted by your drive. Do not attempt to bulk-erase preformatted tape because this renders the tapes unusable.

System Lockup or System Freezing When Running a Tape Backup

If your system locks up or freezes while running a tape backup, follow these steps:

1. Ensure that your system meets at least the minimum requirements for both the tape drive and the backup software.
2. Check for driver or resource (IRQ, DMA, or I/O port address) conflicts with your tape drive controller card or interface; using the floppy drive while making a floppy or parallel port tape backup is a major cause of DMA conflicts.
3. Set the CD-ROM to master and the tape drive to slave if both are using the same IDE port.
4. Check the BIOS boot sequence; ensure that it is not set to ATAPI (tape/CD-ROM) devices if the tape drive is configured as a master device or as a slave with no master.
5. Make sure the hard drive has sufficient free space; most backup programs temporarily use hard drive space as a buffer for data transfer.
6. Hard drive problems can cause the backup software to lock up. Check your hard disk for errors with SCANDISK or a comparable utility.
7. Check for viruses.

8. Check for previous tape drive installations; ensure that any drivers from previous installations are removed.
9. Temporarily disable the current VGA driver and test with the standard 640×480×16 VGA driver supplied by Microsoft. If the problem does not recur, contact your graphics board manufacturer for an updated video driver.
10. Empty the Recycle Bin before attempting a backup. Files in some third-party Recycle Bins can cause backup software to lock up.
11. Disable antivirus programs and Advanced Power Management.
12. Try the tape drive on another computer system and different operating system, or try swapping the drive, card, and cable with known-good, working equipment.

Other Tape Drive Problems

Other issues that might cause problems in general with tape backups include

- Corrupted data or ID information on the tape.
- Incorrect BIOS (CMOS) settings.
- Networking problems (outdated network drivers, and so on).
- A tape that was recorded by another tape drive. If the other drive can still read the tape, this might indicate a head-alignment problem or incompatible environment.

Tape Retensioning

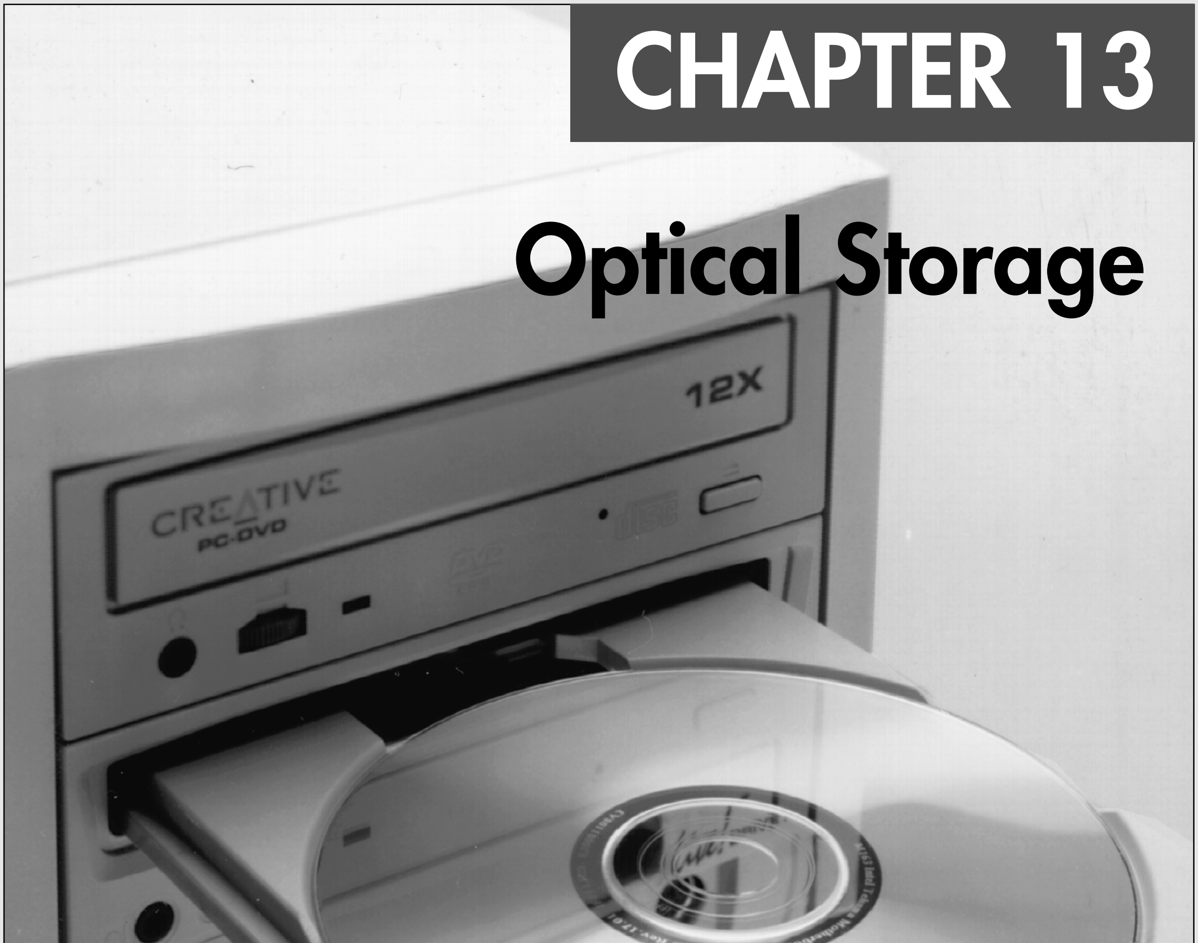
Retensioning a tape is the process of fast-forwarding and then rewinding the tape to ensure that there is even tension on the tape and rollers throughout the entire tape travel. Retensioning is recommended as a preventive maintenance operation when using a new tape or after an existing tape has been exposed to temperature changes or shock (for example, dropping the tape). Retensioning restores the proper tension to the media and removes unwanted tight spots that can develop.

Some general rules for retensioning include the following:

- Retension any tapes that have not been used for more than a month or two.
- Retension tapes if you have errors reading them.
- Retension any tapes that have been dropped.
- In some cases, you might need to perform the retension operation several times to achieve the proper effect. Most tape drive or backup software includes a Retension feature as a menu selection.

CHAPTER 13

Optical Storage



There are basically two types of disk storage for computers: magnetic and optical. *Magnetic* storage is represented by the standard floppy and hard disks that are installed in most PC systems, where the data is recorded magnetically on rotating disks. *Optical* disc storage is similar to magnetic disk storage in basic operation, but it reads and records using light (optically) instead of magnetism. Although most magnetic disk storage is fully read- and write-capable many times over, many optical storage media are either read-only or write-once. Note the convention in which we refer to magnetic as *disk* and optical as *disc*. This is not a law or rule but seems to be followed by most in the industry.

Some media combine magnetic and optical techniques, using either an optical guidance system (called a laser servo) to position a magnetic read/write head (as in the LS-120 or SuperDisk floppy drive) or a laser to heat the disk so it can be written magnetically thus polarizing areas of the track, which can then be read by a lower-powered laser, as in magneto-optical (MO) drives.

At one time, it was thought that optical storage would replace magnetic as the primary online storage medium. However, optical storage has proven to be much slower and far less dense than magnetic storage and is much more adaptable to removable-media designs. As such, optical storage is more often used for backup or archival storage purposes, and as a mechanism by which programs or data can be loaded onto magnetic drives. Magnetic storage, being significantly faster and capable of holding much more information than optical media in the same amount of space, is more suited for direct online storage and most likely won't be replaced in that role by optical storage anytime soon.

The most promising development in the optical area is that in the near future CD-RW (compact disc-rewritable) or DVD+RW (DVD+rewritable) will likely replace the venerable floppy disk as the de facto standard interchangeable, transportable drive and media of choice for PCs. In fact, some would say that has already happened. Most new systems today include a CD-RW drive, and even though a floppy drive is also included with most systems, it is rarely used except for running tests; running diagnostics; or doing basic system maintenance, disk formatting, preparation for OS installation, or configuration.

This chapter investigates the popular and standard forms of optical storage found in modern PCs.

What Is a CD-ROM?

CD-ROM, or *compact disc read-only memory*, is an optical read-only storage medium based on the original CD-DA (digital audio) format first developed for audio CDs. Other formats, such as CD-R (CD-recordable) and CD-RW (CD-rewritable), are expanding the compact disc's capabilities by making it writable. Additionally, new technologies such as DVD (digital versatile disc) are making it possible to store more data than ever on the same size disc.

CD-ROM drives have been considered standard equipment on most PCs for many years now. The primary exceptions to this rule are *thin clients*—PCs intended for use only on networks and which normally lack drives of any type.

CD-ROM is a read-only optical storage medium capable of holding up to 74 or 80 minutes of high-fidelity audio (depending on the disc used), or up to 682MB (74-minute disc) or 737MB (80-minute disc) of data, or some combination of the two, on one side (only the bottom is used) of a 120mm (4.72-inch) diameter, 1.2mm (0.047 inches) thick plastic disc. CD-ROM has exactly the same form factor (physical shape and layout) of the familiar CD-DA audio compact disc and can, in fact, be inserted in a normal audio player. It usually isn't playable, though, because the player reads the subcode information for the track, which indicates that it is data and not audio. If it could be played, the result would be noise—unless audio tracks precede the data on the CD-ROM (see the section "Blue Book—CD EXTRA," later in this chapter). Accessing data from a CD-ROM using a computer is quite a bit faster than from a floppy disk but slower than a modern hard drive. The term *CD-ROM* refers to both the discs themselves and the drive that reads them.

Although only a few dozen CD-ROM discs, or titles, were published by 1988, currently hundreds of thousands of individual titles exist, containing data and programs ranging from worldwide agricultural statistics to preschool learning games. Individual businesses, local and federal government offices, and large corporations also publish thousands of their own limited-use titles. As one example, the storage space and expense that so many business offices once dedicated to the maintenance of a telephone book library can now be replaced by two discs containing the telephone listings for the entire United States.

CDs: A Brief History

In 1979, the Philips and Sony corporations joined forces to co-produce the CD-DA (Compact Disc-Digital Audio) standard. Philips had already developed commercial laserdisc players, and Sony had a decade of digital recording research under its belt. The two companies were poised for a battle—the introduction of potentially incompatible audio laser disc formats—when instead they came to terms on an agreement to formulate a single industry-standard digital audio technology.

Philips contributed most of the physical design, which was similar to the laserdisc format it had created with regards to using pits and lands on the disk that are read by a laser. Sony contributed the digital-to-analog circuitry, and especially the digital encoding and error-correction code designs.

In 1980, the companies announced the CD-DA standard, which has since been referred to as the Red Book format (so named because the cover of the published document was red). The Red Book included the specifications for recording, sampling, and—above all—the 120mm (4.72-inch) diameter physical format you live with today. This size was chosen, legend has it, because it could contain all of Beethoven's approximately 70-minute Ninth Symphony without interruption.

After the specification was set, both manufacturers were in a race to introduce the first commercially available CD audio drive. Because of its greater experience with digital electronics, Sony won that race and beat Philips to market by one month, when on October 1, 1982 Sony introduced the CDP-101 player and the world's first CD recording—Billy Joel's *52nd Street* album. The player was first introduced in Japan and then Europe; it wasn't available in the U.S. until early 1983. In 1984, Sony also introduced the first automobile and portable CD players.

Sony and Philips continued to collaborate on CD standards throughout the decade, and in 1984 they jointly released the Yellow Book CD-ROM standard. It turned the CD from a digital audio storage medium to one that could now store read-only data for use with a computer. The Yellow Book used the same physical format as audio CDs but modified the decoding electronics to allow data to be stored reliably. In fact, all subsequent CD standards (usually referred to by their colored book binders) have referred back to the original Red Book standard for the physical parameters of the disc. With the advent of the Yellow Book standard (CD-ROM), what originally was designed to hold a symphony could now be used to hold practically any type of information or software.

CD-ROM Technology

Although identical in appearance to CD-DAs, CD-ROMs store data instead of (or in addition to) audio. The CD-ROM drives in PCs that read the data discs are almost identical to audio CD players, with the main changes in the circuitry to provide additional error detection and correction. This is to ensure data is read without errors because what would be a minor—if not unnoticeable—glitch in a song would be unacceptable as missing data in a file.

A CD is made of a polycarbonate wafer, 120mm in diameter and 1.2mm thick, with a 15mm hole in the center. This wafer base is stamped or molded with a single physical track in a spiral configuration starting from the inside of the disc and spiraling outward. The track has a pitch, or spiral separation, of 1.6 microns (millionths of a meter, or thousandths of a millimeter). By comparison, an LP record has a physical track pitch of about 125 microns. When viewed from the reading side (the bottom), the disc rotates counterclockwise. If you examined the spiral track under a microscope, you would see that along the track are raised bumps, called *pits*, and flat areas between the pits, called *lands*. It seems strange to call a raised bump a *pit*, but that is because when the discs are pressed, the stamper works from the top side. So, from that perspective, the pits are actually depressions made in the plastic.

The laser used to read the disc would pass right through the clear plastic, so the stamped surface is coated with a reflective layer of metal (usually aluminum) to make it reflective. Then, the aluminum is coated with a thin protective layer of acrylic lacquer, and finally a label or printing is added.

Note

CD-ROM media should be handled with the same care as a photographic negative. The CD-ROM is an optical device and degrades as its optical surface becomes dirty or scratched. Also it is important to note that, although discs are read from the bottom, the layer containing the track is actually much closer to the top of the disc. Writing on the top surface of a disc with a ballpoint pen, for example, easily damages the recording underneath. You need to be careful even when using a marker to write on the disc. The inks and solvents used in some markers can damage the print and lacquer overcoat on the top of the disc, and subsequently the information layer right below. Use only markers designed for writing on CDs. The important thing is to treat both sides of the disc carefully, especially the top (label) side.

Mass-Producing CD-ROMs

Commercial mass-produced CDs are stamped or pressed and not burned by a laser as many people believe (see Figure 13.1). Although a laser is used to etch data onto a glass master disc that has been coated with a photosensitive material, using a laser to directly burn copies would be impractical for the reproduction of hundreds or thousands of copies.

The steps in manufacturing CDs are as follows (use Figure 13.1 as a visual):

1. *Photoresist Coating.* A circular 240mm diameter piece of polished glass 6mm thick is spin-coated with a photoresist layer about 150 microns thick and then hardened by baking at 80°C (176°F) for 30 minutes.
2. *Laser Recording.* A Laser beam recorder (LBR) fires pulses of blue/violet laser light to expose and soften portions of the photoresist layer on the glass master.
3. *Master Development.* A sodium hydroxide solution is spun over the exposed glass master, which then dissolves the areas exposed to the laser, thus etching pits in the photoresist.
4. *Electroforming.* The developed master is then coated with a layer of nickel alloy through a process called *electroforming*. This creates a metal master called a *father*.
5. *Master Separation.* The metal master father is then separated from the glass master. The father is a metal master that can be used to stamp discs, and for short runs, it can in fact be used that way. However, because the glass master is damaged when the father is separated, and because a stamper can produce only a limited number of discs before it wears out, the father often is electroformed to create several reverse image *mothers*. These mothers are then subsequently electroformed to create the actual stampers. This enables many more discs to be stamped without ever having to go through the glass mastering process again.
6. *Disc Stamping Operation.* A metal stamper is used in an injection molding machine to press the data image (pits and lands) into approximately 18 grams of molten (350°C or 662°F) polycarbonate plastic with a force of about 20,000psi. Normally, one disc can be pressed every 3 seconds in a modern stamping machine.

7. *Metalization*. The clear stamped disc base is then sputter-coated with a thin (0.05–0.1 micron) layer of aluminum to make the surface reflective.
8. *Protective Coating*. The metalized disc is then spin-coated with a thin (6–7 micron) layer of acrylic lacquer, which is then cured with UV (ultraviolet) light to protect the aluminum from oxidation.
9. *Finished Product*. Finally, a label or printing is screen-printed on the disc and also cured with UV light.

This manufacturing process is identical for both data CD-ROMs and audio CDs.

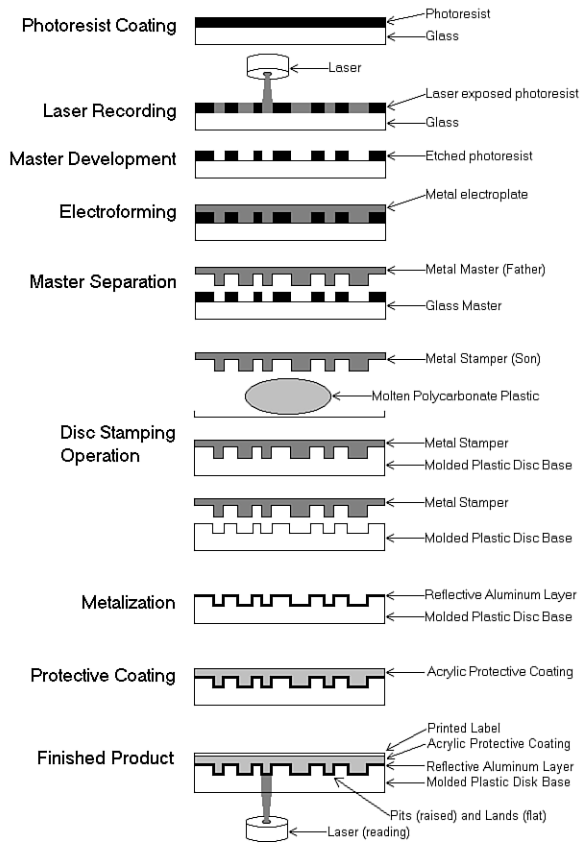


Figure 13.1 CD manufacturing process.

Pits and Lands

Reading the information back is a matter of bouncing a low-powered laser beam off the reflective layer in the disc. The laser shines a focused beam on the underside of the disc, and a photosensitive receptor detects when the light is reflected back. When the light hits a land (flat spot) on the track, the light is reflected back; however, when the light hits a pit (raised bump), no light is reflected back.

As the disc rotates over the laser and receptor, the laser shines continuously while the receptor sees what is essentially a pattern of flashing light as the laser passes over pits and lands. Each time the laser passes over the edge of a pit, the light seen by the receptor changes in state from being reflected to not reflected or vice versa. Each change in state of reflection caused by crossing the edge of a pit is translated into a 1 bit digitally. Microprocessors in the drive translate the light/dark and dark/light (pit edge) transitions into 1 bits, translate areas with no transitions into 0 bits, and then translate the bit patterns into actual data or sound.

The individual pits on a CD are 0.125 microns deep and 0.6 microns wide (1 micron equals one-millionth of a meter). Both the pits and lands vary in length from about 0.9 microns at their shortest to about 3.3 microns at their longest (see Figure 13.2).

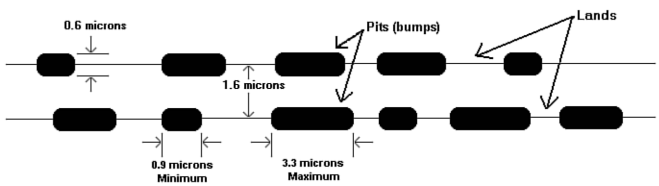

Figure 13.2 Pit and land geometry on a CD.

The pit height above the land is especially critical as it relates to the wavelength of the laser light used when reading the disc. The pit (bump) height is exactly 1/4 of the wavelength of the laser light used to read the disc. Therefore, the light striking a land travels 1/4 + 1/4 = 1/2 of a wavelength further than light striking the top of a pit. This means the light reflected from a pit is 1/2 wavelength out of phase with the rest of the light being reflected from the disc. The out-of-phase waves cancel each other out, dramatically reducing the light that is reflected back and making the pit appear dark even though it is coated with the same reflective aluminum as the lands.

The read laser in a CD drive is a 780nm (nanometer) wavelength laser of about 1 milliwatt in power. The polycarbonate plastic used in the disc has a refractive index of 1.55, so light travels through the plastic 1.55 times more slowly than through the air around it. Because the frequency of the light passing through the plastic remains the same, this has the effect of shortening the wavelength inside the plastic by the same factor. Therefore, the 780nm light waves are now compressed to 780/1.55 = 500nm. One quarter of 500nm is 125nm, which is 0.125 microns—the specified height of the pit.

Drive Mechanical Operation

CD-ROM drives operate in the following manner (see Figure 13.3):

1. The laser diode emits a low-energy infrared beam toward a reflecting mirror.
2. The servo motor, on command from the microprocessor, positions the beam onto the correct track on the CD-ROM by moving the reflecting mirror.
3. When the beam hits the disc, its refracted light is gathered and focused through the first lens beneath the platter, bounced off the mirror, and sent toward the beam splitter.
4. The beam splitter directs the returning laser light toward another focusing lens.
5. The last lens directs the light beam to a photo detector that converts the light into electric impulses.
6. These incoming impulses are decoded by the microprocessor and sent along to the host computer as data.

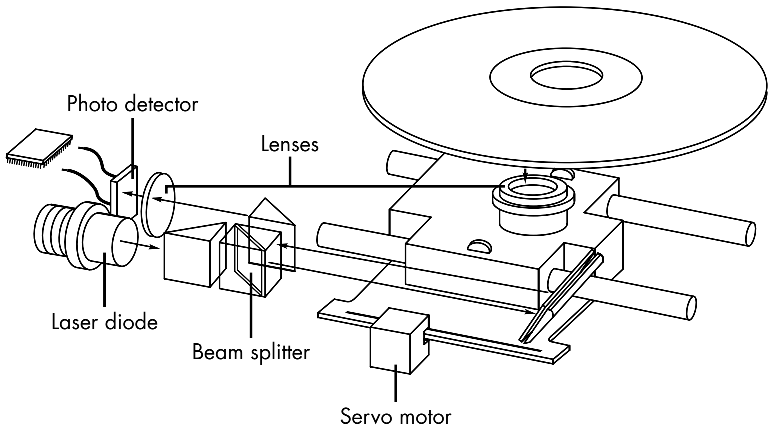

Figure 13.3 Typical components inside a CD-ROM drive.

When first introduced, CD-ROM drives were too expensive for widespread adoption. In addition, drive manufacturers were slow in adopting standards, causing a lag time for the production of CD-ROM titles. Without a wide base of software to drive the industry, acceptance was slow.

After the production costs of both drives and discs began to drop, however, CD-ROMs were rapidly assimilated into the PC world. This was particularly due to the ever-expanding size of PC applications. Virtually all software is now supplied on CD-ROM, even if the disc doesn't contain data representing a tenth of its potential capacity. As the industry stands now, if a software product requires more than one or two floppy disks, it is more economical to put it on a CD-ROM.

For large programs, the advantage is obvious. The Windows 98SE operating system would require more than 75 floppy disks, an amount certainly nobody would want to deal with.

Track and Sectors

The pits are stamped into a single spiral track with a spacing of 1.6 microns between turns, corresponding to a track density of 625 turns per millimeter, or 15,875 turns per inch. This equates to a total of 22,188 turns for a normal 74-minute (650MiB) disc. The disc is divided into six main areas (discussed here and shown in Figure 13.4):

- *Hub clamping area.* The Hub clamp area is just that: a part of the disc where the hub mechanism in the drive can grip the disc. No data or information is stored in that area.
- *Power calibration area (PCA).* This is found only on writable (CD-R/RW) discs and is used only by recordable drives to determine the laser power necessary to perform an optimum burn. A single CD-R or CD-RW disc can be tested this way up to 99 times.
- *Program memory area (PCA).* This is found only on writable (CD-R/RW) discs and is the area where the TOC (table of contents) is temporarily written until a recording session is closed. After the session is closed, the TOC information is written to the lLead-in area.
- *Lead-in.* The lead-in area contains the disc (or session) TOC in the Q subcode channel. The TOC contains the start addresses and lengths of all tracks (songs or data), the total length of the program (data) area, and information about the individual recorded sessions. A single lead-in area exists on a disc recorded all at once (Disc At Once or DAO mode), or a lead-in area starts each session on a multisession disc. The lead-in takes up 4,500 sectors on the disc (1 minute if measured in time, or about 9.2MB worth of data). The lead-in also indicates whether the disc is multisession and what the next writable address on the disc is (if the disc isn't closed).

- *Program (data) area.* This area of the disc starts at a radius of 25mm from the center.
- *Lead-out.* The lead-out marks the end of the program (data) area or the end of the recording session on a multisession disc. No actual data is written in the lead-out; it is simply a marker. The first lead-out on a disc (or the only one if it is a single session or Disk At Once recording) is 6,750 sectors long (1.5 minutes if measured in time, or about 13.8MB worth of data). If the disc is a multisession disc, any subsequent lead-outs are 2,250 sectors long (0.5 minutes in time, or about 4.6MB worth of data

The hub clamp, lead-in, program, and lead-out areas are found on all CDs, whereas only recordable CDs (such as CD-Rs and CD-RWs) have the additional power calibration area and program memory area at the start of the disc.

The center hole in a CD is 15mm in diameter, which means it has a radius of 7.5mm from the center of the disc. From the edge of the center hole to a point at a radius of 20.5mm is the HCA. That is followed by the PCA, which starts at a radius of 20.5mm from the center. The PCA is followed by the PMA, which starts at a radius of 22.35mm, and then the lead-in area, which starts at a radius of 23mm from the center of the disc. The program (data) area of the disc starts at a radius of 25mm from the center, and that is followed by the lead-out area at 58mm. The disc track officially ends at 58.5mm, which is followed by a 1.5mm buffer to the edge of the disc. Figure 13.4 shows these areas in actual relative scale as they appear on a disc.

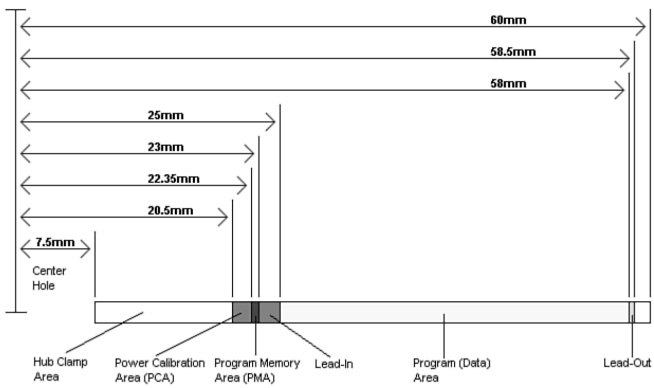

Figure 13.4 Areas on a CD (side view).

Officially, the spiral track of a standard CD-DA or CD-ROM disc starts with this lead-in area and ends at the finish of the lead-out area, which is 58.5mm from the center of the disc, or 1.5mm from the outer edge. This single spiral track is about 5.77 kilometers or 3.59 miles long. An interesting fact is that in a 56x CAV (constant angular velocity) drive, when reading the outer part of the track, the data moves at an actual speed of 162.8 miles per hour (262km/h) past the laser. What is more amazing is that even when the data is traveling at that speed, the laser pickup can accurately read bits (pit/land transitions) spaced as little as only 0.9 microns or 35.4 millionths of an inch apart!

Table 13.1 shows some of the basic information about the two main CD capacities, which are 74- and 80-minute. The CD standard originally was created around the 74-minute disc; the 80-minute versions were added later and basically stretch the standard by tightening up the track spacing a little bit.

Table 13.1 CD-ROM Technical Parameters

Advertised CD length (minutes)	74	80
Advertised CD capacity (MiB)	650	700
1x read speed (m/sec)	1.3	1.3
Track (turn) spacing (um)	1.6	1.48
Turns per mm	625	676
Turns per inch	15,875	17,162
Total track Length (m)	5,772	6,240
Total track length (feet)	18,937	20,472
Total track length (miles)	3.59	3.88
Pit width (um)	0.6	0.6
Pit depth (um)	0.125	0.125
Min. nominal pit length (um)	0.90	0.90
Max. nominal pit length (um)	3.31	3.31
Lead-in inner radius (mm)	23	23
Data inner radius (mm)	25	25
Data outer radius (mm)	58	58
Lead-out outer radius (mm)	58.5	58.5
Data area width (mm)	33	33
Total track area width (mm)	35.5	35.5
Max. rotating speed 1x CLV (rpm)	540	540
Min. rotating speed 1x CLV (rpm)	212	212
Track revolutions (data area)	20,625	22,297
Track revolutions (total)	22,188	23,986

B = Byte (8 bits)
KB = Kilobyte (1,000 bytes)
KiB = Kibibyte (1,024 bytes)
MB = Megabyte (1,000,000 bytes)
MiB = Mebibyte (1,048,576 bytes)
m = meters
mm = millimeters (thousandths of a meter)
um = micrometers = microns (millionths of a meter)
CLV = Constant linear velocity
rpm = revolutions per minute

The spiral track is divided into sectors that are stored at the rate of 75 sectors per second. On a disc that can hold a total of 74 minutes of information, that results in a maximum of 333,000 sectors. Each sector is then divided into 98 individual frames of information. Each frame contains 33 bytes, of which 24 bytes are audio data, 1 byte contains subcode information, and 8 bytes are used for parity/ECC (error correction code) information. Table 13.2 shows the sector, frame, and audio data calculations.

Table 13.2 CD-ROM Sector, Frame, and Audio Data Information

Advertised CD length (minutes)	74	80
Sectors/second	75	75
Frames/sector	98	98

Table 13.2 Continued

Number of sectors	333,000	360,000
Sector length (mm)	17.33	17.33
Byte length (um)	5.36	5.36
Bit length (um)	0.67	0.67
Each Frame:		
Subcode bytes	1	1
Data bytes	24	24
Q+P parity bytes	8	8
Total bytes/frame	33	33
Audio Data:		
Audio sampling rate (Hz)	44,100	44,100
Samples per Hz (stereo)	2	2
Sample size (bytes)	2	2
Audio bytes per second	176,400	176,400
Sectors per second	75	75
Audio bytes per sector	2,352	2,352
Each Audio Sector (98 Frames):		
Q+P parity bytes	784	784
Subcode bytes	98	98
Audio data bytes	2,352	2,352
Bytes/sector RAW (unencoded)	3,234	3,234

Hz = Hertz (cycles per second) *um = micrometers = microns (millionths of a meter)*
mm = millimeters (thousandths of a meter)

Sampling

When music is recorded on a CD, it is sampled at a rate of 44,100 times per second (Hz). Each music sample has a separate left and right channel (stereo) component, and each channel component is digitally converted into a 16-bit number. This allows for a resolution of 65,536 possible values, which represents the amplitude of the sound wave for that channel at that moment.

The sampling rate determines the range of audio frequencies that can be represented in the digital recording. The more samples of a wave that are taken per second, the closer the sampled result will be to the original. The Nyquist theorem (originally published by American physicist Harry Nyquist in 1928) states that the sampling rate must be at least twice the highest frequency present in the sample to reconstruct the original signal accurately. That explains why the 44,100Hz sampling rate intentionally was chosen by Philips and Sony when developing the CD—that rate could be used to accurately reproduce sounds of up to 20,000Hz, which is the upper limit of human hearing.

So, you can see that audio sectors combine 98 frames of 33 bytes each, which results in a total of 3,234 bytes per sector, of which only 2,352 bytes are actual audio data. Besides the 98 subcode bytes per frame, the other 784 bytes are used for parity and error correction.

Subcodes

The subcode bytes enable the drive to find songs (which are confusingly also called *tracks*) along the spiral track and convey additional information about the disc. The subcode bytes are stored as 1 byte per frame, which gives 98 subcode bytes for each sector. Two of these bytes are used as start block and end block markers, leaving 96 bytes of subcode information. These are then divided into eight 12-byte subcode blocks, each of which is assigned a letter designation P–W. Each subcode channel can hold about 31.97MB of data across the disc, which is about 4% of the capacity of an audio disc. The interesting thing about the subcodes is that the data is woven continuously throughout the disc; in other words, subcode data is contained piecemeal in every sector on the disc.

The P and Q subcode blocks are used on all discs, and the R–W subcodes are used only on CD+G (graphics) or CD TEXT–type discs.

The P subcode is used to identify the start of the tracks on the CD. The Q subcode contains a multitude of information, including

- *Whether the sector data is audio (CD-DA) or data (CD-ROM).* This prevents most players from trying to “play” CD-ROM data discs, which might damage speakers due to the resulting noise that would occur.
- *Whether the audio data is two or four channel.* Four channel is rarely if ever used.
- *Whether digital copying is permitted.* CD-R and RW drives ignore this; it was instituted to prevent copying to DAT (digital audio tape) drives.
- *Whether the music is recorded with pre-emphasis.* This is a hiss or noise reduction technique.
- *The track (song) layout on the disc.*
- *The track (song) number.*
- *The minutes, seconds, and frame number from the start of the track (song).*
- *A countdown during an intertrack (intersong) pause.*
- *The minutes, seconds, and frame from the start of the first track (song).*
- *The barcode of the CD.*
- *The ISRC (International Standard Recording Code).* This is unique to each track (song) on the disc.

The R-W subcodes are used on CD+G (graphics) discs to contain graphics and text. This enables a limited amount of graphics and text to be displayed while the music is being played. These same subcodes are used on CD TEXT discs to store disc- and track-related information that is added to standard audio CDs for playback on compatible CD audio players. The CD TEXT information is stored as ASCII characters in the R–W channels in the lead-in and program areas of a CD. On a CD TEXT disc, the lead-in area subcodes contain text information about the entire disc, such as the album, track (song) titles, and artist names. The program area subcodes, on the other hand, contain text information for the current track (song), including track title, composer, performers, and so on. The CD TEXT data is repeated throughout each track to reduce the delay in retrieving the data.

CD TEXT–compatible players typically have a text display to show this information, ranging from a simple one- or two-line, 20-character display such as on many newer RBDS (radio broadcast data system) automobile radio/CD players up to 21 lines of 40-color, alphanumeric or graphics characters on home- or computer-based players. The specification also allows for future additional data, such as Joint Photographics Expert Group (JPEG) images. Interactive menus also can be used for the selection of text for display.

Handling Errors

Handling errors was a big part of the original Red Book CD standard. CDs use parity and interleaving techniques called *cross-interleave Reed-Solomon code (CIRC)* to minimize the effects of errors on the disk. This works at the frame level. When being stored, the 24 data bytes in each frame are first run through a Reed-Solomon encoder to produce a 4-byte parity code called "Q" parity, which then is added to the 24 data bytes. The resulting 28 bytes are then run though another encoder that uses a different scheme to produce an additional 4-byte partity value called "P" parity. These are added to the 28 bytes from the previous encoding, resulting in 32 bytes (24 of the original data plus the Q and P parity bytes). An additional byte of subcode (tracking) information is then added, resulting in 33 bytes total for each frame. Note that the P and Q parity bytes are not related to the P and Q subcodes mentioned earlier.

To minimize the effects of a scratch or physical defect that would damage adjacent frames, several interleaves are added before the frames are actually written. Parts of 109 frames are cross-interleaved (stored in different frames and sectors) using delay lines. This scrambling decreases the likelihood of a scratch or defect affecting adjacent data because the data is actually written out of sequence.

With audio CDs and CD-ROMs, the CIRC scheme can correct errors up to 3,874 bits long (which would be 2.6mm in track length). In addition, for audio CDs, only the CIRC can also conceal (through interpolation) errors up to 13,282 bits long (8.9mm in track length). Interpolation is the process in which the data is estimated or averaged to restore what is missing. That would of course be unacceptable on a CD-ROM data disc, so this applies only to audio discs. The Red Book CD standard defines the *block error rate (BLER)* as the number of frames (98 per sector) per second that have any bad bits (averaged over 10 seconds) and requires that this be less than 220. This allows a maximum of up to about 3% of the frames to have errors, and yet the disc will still be functional.

An additional layer of error detection and correction circuitry is the key difference between audio CD players and CD-ROM drives. Audio CDs convert the digital information stored on the disc into analog signals for a stereo amplifier to process. In this scheme, some imprecision is acceptable because it would be virtually impossible to hear in the music. CD-ROMs, however, can't tolerate any imprecision. Each bit of data must be read accurately. For this reason, CD-ROM discs have a great deal of additional ECC information written to the disc along with the actual stored information. The ECC can detect and correct most minor errors, improving the reliability and precision to levels that are acceptable for data storage.

In the case of an audio CD, missing data can be interpolated—that is, the information follows a predictable pattern that enables the drive to guess the missing values. For example, if three values are stored on an audio disc, say 10, 13, and 20 appearing in a series, and the middle value is missing—because of damage or dirt on the CD's surface—you could interpolate a middle value of 15, which is midway between 10 and 20. Although this might not be exactly correct, in the case of audio recording, it will not be noticeable to the listener. If those same three values appear on a CD-ROM in an executable program, there is no way to guess at the correct value for the middle sample. Interpolation can't work because executable program instructions or data must be exact; otherwise, the program will crash or improperly read data needed for a calculation. Using the previous example with a CD-ROM running an executable program, to guess 15 is not merely slightly off, it is completely wrong.

In a CD-ROM on which data is stored instead of audio information, additional information is added to each sector to detect and correct errors as well as to identify the location of data sectors more accurately. To accomplish this, 304 bytes are taken from the 2,352 that originally were used for audio data and are instead used for sync (synchronizing bits), ID (identification bits), ECC, and EDC information. This leaves 2,048 bytes for actual user data in each sector. Just as when reading an audio CD, on a 1x (standard speed) CD-ROM, sectors are read at a constant speed of 75 per second. This results in a standard CD-ROM transfer rate of $2{,}048 \times 75 = 153{,}600$ bytes per second, which is expressed as either 153.6KB/sec or 150KiB/sec.

CD Capacity

Because a typical disc can hold a maximum of 74 minutes of data, and each second contains 75 blocks of 2,048 bytes each, you can calculate the absolute maximum storage capacity of a CD-ROM at 681,984,000 bytes—rounded as 682MB (megabytes) or 650MiB (mebibytes). Table 13.3 shows the structure and layout of each sector on a CD-ROM on which data is stored.

Table 13.3 CD-ROM Sector Information and Capacity

Each Data Sector (Mode 1):	74-minute	80-minute
Q+P parity bytes	784	784
Subcode bytes	98	98
Sync bytes	12	12
Header bytes	8	8
ECC/EDC bytes	284	284
Data bytes	2,048	2,048
Bytes/sector RAW (unencoded)	3,234	3,234
Actual CD-ROM Data Capacity:		
B	681,984,000	737,280,000
KiB	666,000	720,000
KB	681,984	737,280
MiB	650.39	703.13
MB	681.98	737.28

B = Byte (8 bits)
KB = Kilobyte (1,000 bytes)
KiB = Kibibyte (1,024 bytes)
MB = Megabyte (1,000,000 bytes)
MiB = Mebibyte (1,048,576 bytes)
ECC = Error correction code
EDC = Error detection code

This information assumes the data is stored in Mode 1 format, which is used on virtually all data discs. You can learn more about the Mode 1/Mode 2 formats in the section on the Yellow Book and XA standards later in this chapter.

With data sectors, you can see that out of 3,234 actual bytes per sector, only 2,048 are actual CD-ROM user data. Most of the 1,186 other bytes are used for the intensive error detection and correction schemes to ensure error-free performance.

Data Encoding on the Disc

The final part of how data is actually written to the CD is very interesting. After all 98 frames are composed for a sector (whether audio or data), the information is then run through a final encoding process called EFM (eight to fourteen modulation). This scheme takes each byte (8 bits) and converts it into a 14-bit value for storage. The 14-bit conversion codes are designed so that there are never less than 2 or more than 10 adjacent 0 bits. This is a form of Run Length Limited (RLL) encoding called RLL 2,10 (RLL x,y where x = the minimum and y = the maximum run of 0s). This is designed to prevent long strings of 0s, which could more easily be misread, as well as to limit the minimum and maximum frequency of transitions actually placed on the recording media. With as few as 2 or as many as 10 0 bits separating 1 bits in the recording, the minimum distance between 1s is three bit time intervals (usually refered to as 3T) and the maximum spacing between 1s is 11 time intervals (11T).

Because some of the EFM codes start and end with a 1 or more than five 0s, three additional bits called *merge bits* are added between each 14-bit EFM value written to the disc. The merge bits usually are 0s but might contain a 1 if necessary to break a long string of adjacent 0s formed by the adjacent 14-bit EFM values. In addition to the now 17-bits created for each byte (EFM plus merge bits), a 24-bit sync word (plus 3 more merge bits) is added to the beginning of each frame. This results in a total of 588 bits (73.5 bytes) actually being stored on the disc for each frame. Multiply this for 98 frames per sector and you have 7,203 bytes actually being stored on the disc to represent each sector. A 74-minute disc, therefore, really has something like 2.4GB of actual data being written, which after being fully decoded and stripped of error correcting codes and other information, results in about 682MB (650MiB) of actual user data.

The calculations for EFM encoded frames and sectors are shown in Table 13.4.

Table 13.4 EFM Encoded Data Calculations

EFM-Encoded Frames:	74-minute	80-minute
Sync word bits	24	24
Subcode bits	14	14
Data bits	336	336
Q+P parity bits	112	112
Merge bits	102	102
EFM bits per frame	588	588
EFM Encoded Sectors:		
EFM bits per sector	57,624	57,624
EFM bytes per sector	7,203	7,203
Total EFM data on disc (MB)	2,399	2,593

B = Byte (8 bits)
KB = Kilobyte (1,000 bytes)
KiB = Kibibyte (1,024 bytes)
MB = Megabyte (1,000,000 bytes)
MiB = Mebibyte (1,048,576 bytes)
EFM = Eight to fourteen modulation

To put this into perspective, see Table 13.5 for an example of what familar data would actually look like when written to a CD. As an example, I'll use the letters "N" and "O" as they would be written on the disk. Here are the computer representations of these letters.

Table 13.5 How Data Is Written to a CD

Character	"N"	"O"
ASCII decimal code	78	79
ASCII hexadecimal code	4E	4F
ASCII binary code	01001110	01001111
EFM code	00010001000100	00100001000100

ASCII = American Standard Code for Information Interchange
EFM = Eight to fourteen modulation

Figure 13.5 shows how this data would look when actually written to a CD.

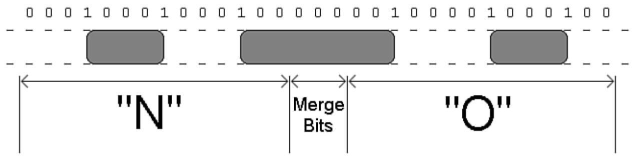

Figure 13.5 EFM data encoding on a CD.

The edges of the pits are translated into the binary 1 bits. As you can see, each 14-bit grouping is used to represent a byte of actual EFM encoded data on the disc, and each 14-bit EFM code is separated by three merge bits (all 0s in this example). The three pits produced by this example are 4T (4 transitions), 8T, and 4T long. The string of 1s and 0s on the top of the figure represent how the actual data would be read; note that a 1 is read wherever a pit-to-land transition occurs. It is interesting to note that this drawing is actually to scale, meaning the pits (raised bumps) would be about that long and wide relative to each other. If you could use a microscope to view the disc, this is what the word "NO" would look like as actually recorded.

CD Drive Speed

When a drive seeks out a specific data sector or musical track on the disc, it looks up the address of the data from a table of contents contained in the lead-in area and positions itself near the beginning of this data across the spiral, waiting for the right string of bits to flow past the laser beam.

Because CDs originally were designed to record audio, the speed at which the drive reads the data had to be constant. To maintain this constant flow, CD-ROM data is recorded using a technique called *constant linear velocity (CLV)*. This means that the track (and thus the data) is always moving past the read laser at the same speed, which originally was defined as 1.3 meters per second. Because the track is a spiral that is wound more tightly near the center of the disc, the disc must spin at various rates to maintain the same track linear speed. In other words, to maintain a CLV, the disk must spin more quickly when reading the inner track area and more slowly when reading the outer track area. The speed of rotation in a 1x drive (1.3 meters per second is considered 1x speed) varies from 540rpm when reading the start (inner part) of the track down to 212rpm when reading the end (outer part) of the track.

In the quest for greater performance, drive manufacturers began increasing the speeds of their drives by making them spin more quickly. A drive that spins twice as fast was called a 2x drive, one that spins four times faster was called 4x, and so on. This was fine until about the 12x point, where drives were spinning discs at rates from 2,568rpm to 5,959rpm to maintain a constant data rate. At higher speeds than this, it became difficult to build motors that could change speeds (spin up or down) as quickly as necessary when data was read from different parts of the disc. Because of this, most drives rated faster than 12x spin the disc at a fixed rotational, rather than linear speed. This is termed *constant angular velocity (CAV)* because the angular velocity (or rotational speed) is what remains a constant.

CAV drives are also generally quieter than CLV drives because the motors don't have to try to accelerate or decelerate as quickly. A drive (such as most rewritables) that combines CLV and CAV technologies is referred to as *Partial-CAV* or *P-CAV*. Most writable drives, for example, function in CLV mode when burning the disc and in CAV mode when reading. Table 13.6 compares CLV and CAV.

Table 13.6 CLV Versus CAV Technology Quick Reference

	CLV (Constant Linear Velocity)	CAV (Constant Angular Velocity)
Speed of CD rotation:	Varies with data position on CD—faster on inner tracks than on outer tracks	Constant
Data transfer rate:	Constant	Varies with data position on CD—faster on outer tracks than on inner tracks
Noise level:	Higher	Lower

CD-ROM drives have been available in speeds from 1x up to 56x and beyond. Most nonrewritable drives up to 12x were CLV; most drives from 16x and up are CAV. With CAV drives, the track data is moving past the read laser at various speeds, depending on where the data is physically located on the CD (near the inner or outer part of the track). This also means that CAV drives read the data at the edge of the disk more quickly than data near the center. This allowed for some misleading

Table 13.7 CD-ROM Drive Speeds and Transfer Rates

Column 1	Column 2	Column 3	Column 4	Column 5	Column 6
Advertised CD-ROM Speed (Max. if CAV)	Time to Read 74-minute CD if CLV	Time to Read 80-minute CD if CLV	Transfer Rate (Bytes/sec) (Max. if CAV)	Actual CD-ROM Speed Minimum if CAV	Minimum Transfer Rate if CAV (Bytes/sec)
1x	74.0	80.0	153,600	0.4x	61,440
2x	37.0	40.0	307,200	0.9x	138,240
4x	18.5	20.0	614,400	1.7x	261,120
6x	12.3	13.3	921,600	2.6x	399,360
8x	9.3	10.0	1,228,800	3.4x	522,240
10x	7.4	8.0	1,536,000	4.3x	660,480
12x	6.2	6.7	1,843,200	5.2x	798,720
16x	4.6	5.0	2,457,600	6.9x	1,059,840
20x	3.7	4.0	3,072,000	8.6x	1,320,960
24x	3.1	3.3	3,686,400	10.3x	1,582,080
32x	2.3	2.5	4,915,200	13.8x	2,119,680
40x	1.9	2.0	6,144,000	17.2x	2,641,920
48x	1.5	1.7	7,372,800	20.7x	3,179,520
50x	1.5	1.6	7,680,000	21.6x	3,317,760
52x	1.4	1.5	7,987,200	22.4x	3,440,640
56x	1.3	1.4	8,601,600	24.1x	3,701,760

advertising when these drives first came out. For example, a 12x CLV drive reads data at 1.84MB/sec no matter where that data is on the disc. On the other hand, a 16x CAV drive reads data at speeds up to 16x (2.46MB/sec) on the outer part of the disc, but it also reads at a much lower speed of only 6.9x (1.06MB/sec) when reading the inner part of the disc. On average, this would be only 11.5x, or about 1.76MB/sec. The average is actually overly optimistic because discs are read from the inside (slower part) out, and an average would relate only to reading completely full discs. The real-world average could be much less than that.

What this all means is that the 12x CLV drive would be noticeably faster than the 16x drive, and faster than even a 20x drive! Remember that all advertised speeds on CAV drives are only the maximum transfer speed the drive can achieve, and it can achieve that only when reading the very end part of the disc.

Table 13.7 contains data showing CD-ROM drive speeds along with transfer rates and other interesting data.

Column 7	Column 8	Column 9	Column 10	Column 11	Column 12
Average CD-ROM Speed if CAV	**Average Transfer Rate if CAV (Bytes/sec)**	**Maximum Linear Speed (m/sec)**	**Maximum Linear Speed (mph)**	**Speed Min. if CLV Max. if CAV (rpm)**	**Rotational Speed Max. if CLV (rpm)**
0.7x	107,520	1.3	2.9	214	497
1.5x	222,720	2.6	5.8	428	993
2.9x	437,760	5.2	11.6	856	1,986
4.3x	660,480	7.8	17.4	1,284	2,979
5.7x	875,520	10.4	23.3	1,712	3,973
7.2x	1,098,240	13.0	29.1	2,140	4,966
8.6x	1,320,960	15.6	34.9	2,568	5,959
11.5x	1,758,720	20.8	46.5	3,425	7,945
14.3x	2,196,480	26.0	58.2	4,281	9,931
17.2x	2,634,240	31.2	69.8	5,137	11,918
22.9x	3,517,440	41.6	93.1	6,849	15,890
28.6x	4,392,960	52.0	116.3	8,561	19,863
34.4x	5,276,160	62.4	139.6	10,274	23,835
35.8x	5,498,880	65.0	145.4	10,702	24,828
37.2x	5,713,920	67.6	151.2	11,130	25,821
40.1x	6,151,680	72.8	162.8	11,986	27,808

Each of the columns in Table 13.7 contains interesting information, explained here:

- *Column 1.* Indicates the advertised drive speed. This is a constant speed if the drive is CLV (most 12x and lower) or a maximum speed only if CAV.
- *Columns 2 and 3.* Indicate how long it would take to read a full disc if the drive was CLV. For CAV drives, those figures would be longer because the average read speed is less than the advertised speed. The fourth column indicates the data transfer rate, which for CAV drives would be a maximum figure only when reading the end of a disc.
- *Columns 3–6.* Indicate the actual minimum "x" speed for CAV drives, along with the minimum transfer speed (when reading the start of any disc) and an optimistic average speed (true only when reading a full disc; otherwise, it would be even lower) in both "x" and byte-per-second formats.
- *Columns 7–8.* Indicate the maximum linear speeds the drive will attain, in both meters per second and miles per hour. CLV drives maintain those speeds everywhere on the disc, whereas CAV drives reach those speeds only on the outer part of a disc.
- *Columns 9–12.* Indicate the rotational speeds of a drive. The first of those shows how fast the disc spins when reading the start of a disc; this would apply to either CAV or CLV drives. For CAV drives, that figure is constant no matter where on the disc it is reading. The last column shows the maximum rotational speed if the drive were a CLV type. Because most drives over 12x are CAV, those figures are mostly theoretical for the 16x and faster drives.

Vibration problems can cause high-speed drives to drop to lower speeds to enable reliable reading of CD-ROMs. Your CD-ROM can become unbalanced, for example, if you apply a small paper label to its surface to identify the CD or affix its serial number or code for easy reinstallation. For this reason, many of the faster CD and DVD drives come with autobalancing or vibration-control mechanisms to overcome these problems. The only drawback is that if they detect a vibration, they slow down the disc, thereby reducing the transfer rate performance. .

TrueX Technology

Drives that are 16x or faster are usually CAV drives. Even with CAV, at these speeds the rotational speed of the disc is nearly 12,000rpm and the data is moving at nearly 163 miles per hour past the laser on the outer part of the track! Rather than try to spin discs even faster for higher speeds, a company called Zen Research has developed a technology they call TrueX, (also called Multibeam), which uses multiple laser beams to achieve constant high transfer rates without the limitations of CAV. Currently, this technology is licensed by several companies, although Kenwood has been the primary promotor and manufacturer of TrueX drives and has released drives in 42x, 52x, 62x, and 72x models, which have benchmarked as the fastest CD-ROM drives available.

TrueX drives use a diffraction grating to split a single beam into seven beams reading seven tracks simultaneously to improve the transfer rate while maintaining a slower rotational speed that reduces noise and vibration. Drives with TrueX technology are the fastest CD-ROM drives on the market, capable of sustaining near-CLV performance at high speeds consistently no matter where they are reading on the disc.

The net effect is that the reading speed is consistently higher than equivelant speed CAV drives, and yet the TrueX drives spin at a slower speed. For example, a 52x CAV drive performs from about 22x at the start of a disk to 52x at the end, whereas a 52x TrueX drive performs at about 45x at the start of a disc to 52x at the end. This results in a much higher average performance that is nearly consistent with CLV drives.

One drawback is that this technology is useful only for reading (and not writing). This means that for reading information, TrueX CD-ROM drives are the fastest CD-ROM drives on the market.

Compact Disc and Drive Formats

After Philips and Sony had created the Red Book CD-DA format discussed earlier in the chapter, they began work on other format standards that would allow CDs to store computer files, data, and even video and photos. These standards control how the data is formatted so that the drive can read it, and additional file format standards can then control how the software and drivers on your PC can be designed to understand and interpret the data properly. Note that the physical format and storage of data on the disc as defined in the Red Book was adopted by all subsequent CD standards. This refers to the encoding and basic levels of error correction provided by CD-DA discs. What the other "books" specify is primarily how the 2,352 bytes in each sector are to be handled, what type of data can be stored, how it should be formatted, and more.

All the official CD standard books and related documents can be purchased from Philips for $100–$150 each. See the Philips licensing site at `http://www.licensing.philips.com` for more information.

Table 13.8 describes the various standard CD formats.

Table 13.8 Compact Disc Formats

Format	Name	Introduced	Notes
Red Book	CD-DA (compact disc digital audio)	1980 - by Philips and Sony	The original CD audio standard on which all subsequent CD standards are based.
Yellow Book	CD-ROM (compact disc read-only memory)	1983 - by Philips and Sony	Specifies additional ECC and EDC for data in several sector formats, including Mode 1 and Mode 2.
Green Book	CD-i (compact disc-interactive)	1986 - by Philips and Sony	Specifies an interactive audio/video standard for nonPC-dedicated player hardware (now mostly obsolete) and discs used for interactive presentations. Defines Mode 2, Form 1 and Mode 2, Form 2 sector formats along with interleaved MPEG-1 video and ADPCM audio.
CD-ROM XA	CD-ROM XA (extended architecture)	1989 - by Philips, Sony, and Microsoft	Combines Yellow Book and CD-i to bring CD-i audio and video capabilities to PCs.
Orange Book	CD-R (recordable) and CD-RW (rewritable)	1989 - by Philips and Sony (Part I/II); 1996 - by Philips and Sony (Part III)	Defines single session, multisession, and packet writing on recordable discs. Part I—CD-MO (magneto-optical, withdrawn). Part II—CD-R (recordable). Part III—CD-RW (rewritable).
Photo-CD	CD-P	1990 - by Philips and Kodak	Combines CD-ROM XA with CD-R multisession capability in a standard for photo storage on CD-R discs.

Table 13.8 Continued

Format	Name	Introduced	Notes
White Book	Video CD	1993 - by Philips, JVC, Matsushita, and Sony	Based on CD-i and CD-ROM XA. It stores up to 74 minutes of MPEG-1 video and ADPCM digital audio data.
Blue Book	CD EXTRA (formerly CD-Plus or enhanced music)	1995 - by Philips and Sony	Multisession format for stamped discs; used by musical artists to incorporate videos, liner notes, and other information on audio CDs.

Red Book—CD-DA

The Red Book introduced by Philips and Sony in 1980 is the father of all compact-disc specifications because all other "books" or formats are based on the original CD-DA Red Book format. For more information on the Red Book format, see the section "CDs: A Brief History" at the beginning of this chapter.

The Red Book specification includes the main parameters, audio specification, disc specification, optical stylus, modulation system, error correction system, and the control and display system. The latest revision of the Red Book is dated May 1999.

Yellow Book—CD-ROM

The Yellow Book was first published by Philips, Sony, and Microsoft in 1983 and has been revised and amended several times since. The Yellow Book standard took the physical format of the original CD-DA, or Red Book, standard and added another layer of error detection and correction to enable data to be stored reliably. It also added additional synchronization and header information to enable sectors to be more accurately located. Yellow Book specifies two types of sectoring—called Mode 1 (with error correction) and Mode 2—which offer different levels of error detection and correction schemes. Some data (computer files, for example) can't tolerate errors. However, other data, such as a video image or sound, can tolerate minor errors. By using a mode with less error correction information, more data can be stored, but with the possibility of uncorrected errors.

In 1989, the Yellow Book was issued as an international standard by the ISO as *ISO/IEC 10149, Data Interchange on Read-Only 120mm Optical Discs (CD-ROM)*. The latest version of the Yellow Book is dated May 1999.

Green Book—CD-i

The Green Book was published by Philips and Sony in 1986. CD-i is much more than just a disc format; instead it is a complete specification for an entire interactive system consisting of custom hardware (players) designed to be connected to a television, software designed to deliver video and audio together with user interactivity in real time, and the media and format. A CD-i player is actually a dedicated computer usually running a variant on the Motorola 68000 processor line, as well as a customized version of the Microware OS/9 Real Time Operating System.

CD-i enables both audio and video to share a disc and enables the information to be interleaved so as to maintain syncronization between the pictures and sounds. To fit both audio and video in the same space originally designed for just audio, compression was performed. The video was compressed using the Moving Picture Experts Group-1 (MPEG-1) compression standard, whereas the audio was compressed with adaptive differential pulse code modulation (ADPCM). ADPCM is an audio encoding algorithm that takes about half the space for the same quality of standard PCM, and even less if quality is reduced by lowering the sampling rate or bits per sample. Using ADPCM, up to 8 hours of stereo or 16 hours of mono sound can fit on one CD. The "differential" part of ADPCM refers to the fact that it records the differences between one signal and the next (using only 4-bit numbers), which reduces the total amount of data involved. ADPCM audio can be interleaved with video in CD-i (and CD-ROM XA) applications.

The Yellow Book defines two CD-ROM sector structures, called Mode 1 and Mode 2. The Green Book (CD-i) refines the Mode 2 sector definition by adding two forms, called Mode 2, Form 1 and Mode 2, Form 2. The Mode 2, Form 1 sector definition uses ECC and allows for 2,048 bytes of data storage like the Yellow Book Mode 1 sectors, but it rearranged things slightly to use the 8 formerly unused (blank or 0) bytes as a subheader containing additional information about the sector. The Mode 2, Form 2 definition drops the ECC and allows 2,324 bytes for data. Without the ECC, only video or audio information should be stored in Form 2 sectors because that type of information can tolerate minor errors.

Media or titles available for CD-i include all manner of educational and training applications, games, encyclopedias, karaoke, and movies. Note that CD-i discs can't be "played" on PCs. In fact, because the files are in an OS/9 file format, your PC won't even be capable of seeing the files on the disc! Even so, drivers have been written that can be installed and will enable viewing the files, and one enterprising individual has even written a CD-i emulator called CD-iCE that emulates a CD-i player thus enabling CD-i applications to be run. You can find out more about the CD-iCE emulator at `http://www.emuhq.com/cdi`.

Today. the CD-i format is largely obsolete. The last revision of the standard was produced in May 1994. Philips sold off its entire consumer CD-i catalogue to Infogrames Multimedia in 1998, which now owns the rights for virtually all consumer CD-i titles ever produced. Philips made a final run of CD-i players in 1999, and it is doubtful any new ones will ever be produced. The legacy of CD-i lives on in the other formats that use specifications originally devised for CD-i, such as the Mode 2, Form 1 and Form 2 sector structures later used in CD-XA and the MPEG-1 video format later used in the White Book (CD-Video).

CD-ROM XA

CD-ROM XA originally was defined in 1989 by Philips, Sony, and Microsoft as a supplement to the Yellow Book. CD-ROM XA brings some of the features originally defined in the Green Book (CD-i) to the Yellow Book (CD-ROM) standard, especially for multimedia use. CD-ROM XA adds three main features to the Yellow Book standard. The first consists of the CD-i–enhanced sector definitions (called forms) for the Mode 2 sectors, and the second is a capability called interleaving (mixing audio and video information). The third is ADPCM for compressed audio. The latest version of the CD-ROM XA standard was released in May 1991.

Interleaving

CD-ROM XA drives can employ a technique known as interleaving. The specification calls for the capability to encode on disc whether the data directly following an identification mark is graphics, sound, or text. Graphics can include standard graphics pictures, animation, or full-motion video. In addition, these blocks can be interleaved, or interspersed, with each other. For example, a frame of video can start a track followed by a segment of audio, which would accompany the video, followed by yet another frame of video. The drive picks up the audio and video sequentially, buffering the information in memory and then sending it along to the PC for synchronization.

In short, the data is read off the disc in alternating pieces and then synchronized at playback so that the result is a simultaneous presentation of the data. Without interleaving, the drive would have to read and buffer the entire video track before it could read the audio track and synchronize the two for playback.

Sector Modes and Forms

Mode 1 is the standard Yellow Book CD sector format with ECC and EDC to enable error-free operation. Each Mode 1 sector is broken down as shown in Tables 13.9 and 13.10.

Table 13.9 Yellow Book Mode 1 Sector Format Breakdown

Yellow Book (CD-ROM) Sectors (Mode 1):	
Q+P parity bytes	784
Subcode bytes	98
Sync bytes	12
Header bytes	4
Data bytes	2,048
EDC bytes	4
Blank (0) bytes	8
ECC bytes	276
Bytes/sector RAW (unencoded)	3,234

Table 13.10 Yellow Book (CD-ROM) Mode 1 Sector Format

Sync	Header	User Data	EDC	Blank	ECC
12	4	2,048	4	8	276

Mode 2 was defined as a sector without any ECC or EDC in the original Yellow Book. Unfortunately, Mode 1 (which had ECC and EDC) couldn't be mixed with Mode 2 sectors on the same track (program or song). To enable data with and without error detection and correction in a single track, new sector format subsets for Mode 2 sectors were added in the Green Book (CD-i) and subsequently adopted in the CD-ROM XA extensions. This enabled information that would not tolerate errors (such as programs or computer data) to be interleaved or mixed within the same track with information that would tolerate errors (such as audio or video data). These variations on Mode 2 include Form 1 and Form 2 sectors. Each Mode 2, Form 1 sector is broken down as shown in Tables 13.11, 13.12, 13.13, and 13.14.

Table 13.11 Green Book Mode 1 Sector Format Breakdown

Green Book/CD-ROM XA Sectors (Mode 2, Form 1):	
Q+P parity bytes	784
Subcode bytes	98
Sync bytes	12
Header bytes	4
Subheader bytes	8
Data bytes	2,048
EDC bytes	4
ECC bytes	276
Bytes/sector RAW (unencoded)	3,234

Table 13.12 Green Book/CD-ROM XA (Yellow Book Extensions) Mode 2, Form 1 Sector Format

Sync	Header	Subheader	User Data	EDC	ECC
12	4	8	2,048 bytes	4	276

Table 13.13 Green Book Mode 2 Sector Format Breakdown

Green Book/CD-ROM XA Sectors (Mode 2, Form 2):	
Q+P parity bytes	784
Subcode bytes	98
Sync bytes	12
Header bytes	4
Subheader bytes	8
Data bytes	2,324
EDC bytes	4
Bytes/sector RAW (unencoded)	3,234

Table 13.14 Green Book/CD-ROM XA (Yellow Book Extensions) Mode 2, Form 2 Sector Format

Sync	Header	Subheader	User Data	EDC
12	4	8	2,324 bytes	4

Both Mode 2 sector formats add a subheader field that identifies the type of information (such as audio or video) carried in the user data field. The Form 2 sector lacks the ECC of the Form 1 sector and increases the size of the user data field instead. This type of sector is for storing audio or video data that can tolerate errors.

Because they don't use any third-level error correction, CD-ROMs that use the Mode 2, Form 2 sector format (such as MPEG video CDs) can hold more user information than other CD-ROM types in the same number of sectors, and as a result also have a higher data transfer rate of 174.3KB/sec instead of the standard 153.6KB/sec. Note that Form 2 sectors are never used to store data or program files because errors can't be tolerated in that type of information. In that case, the Mode 2, Form 1 sector format would be used.

For a drive to be truly XA compatible, the audio data written in Form 2 sectors on the disc as audio must be ADPCM audio—specially compressed and encoded audio. This requires that the drive or the SCSI controller have a signal processor chip that can decompress the audio during the synchronization process.

Some earlier drives were called XA-ready, which meant they were capable of Mode 2, Form 1 and Form 2 reading but did not incorporate the ADPCM chip. This is not a signficant shortcoming, however, because only certain multimedia titles use the ADPM encoding (with interleaved audio and video). The main benefit XA brought to the table was the additional sector modes and forms taken from the Green Book.

Orange Book

The Orange Book defines the standards for recordable CDs and originally was announced in 1989 by Philips and Sony. The Orange Book comes in three parts: Part I describes a format called CD-MO (magneto-optical), which was to be a rewritable format but was withdrawn before any products really came to market; Part II (1989) describes CD-R; and Part III (1996) describes CD-RW. Note that originally, CD-R was refered to as CD-WO (write-once), and CD-RW originally was called CD-E (erasable).

The Orange Book Part II CD-R design is known as a WORM (write once read mostly) format. After a portion of a CD-R disc is recorded, it can't be overwritten or reused. Recorded CD-R discs are Red Book and Yellow Book compatible, which means they are readable on conventional CD-DA or CD-ROM drives. The CD-R definition in the Orange Book Part II is divided into two volumes. Volume 1 defines recording speeds of 1x, 2x, and 4x the standard CD speed; the last revision, dated December 1998, is 3.1. Volume 2 defines recording speeds up to 16x the standard CD speed, and the last version released, 0.9, is dated December 2000.

The Orange Book Part III describes CD-RW. As the name implies, CD-RW enables you to erase and overwrite information in addition to reading and writing. The Orange Book Part III CD-RW definition was broken into two volumes. Volume 1 defines recording speeds of 1x, 2x, and 4x times the standard CD speed; the latest version, 2.0, is dated August 1998. Volume 2 defines recording speeds from 4x to 10x standard CD speed, and is sometimes refered to as high-speed CD-RW; the latest version, 1.0, is dated May 2000.

Besides the capability to record on CDs, the most important features instituted in the Orange Book specification is the capability to do multisession recording.

Multisession Recording

Before the Orange Book specification, CDs had to be written as a single session. A *session* is defined as a lead-in, followed by one or more tracks of data (or audio), followed by a lead-out. The lead-in takes up 4,500 sectors on the disc (1 minute if measured in time or about 9.2MB worth of data). The lead-in also indicates whether the disc is multisession, and what the next writable address on the disc is (if the disc isn't closed). The first lead-out on a disc (or the only one if it is a single session or Disk At Once recording) is 6,750 sectors long (1.5 minutes if measured in time or about 13.8MB worth of data). If the disc is a multisession disc, any subsequent lead-outs are 2,250 sectors long (0.5 minutes in time or about 4.6MB worth of data).

A multisession CD has multiple sessions, with each individual session complete from lead-in to lead-out. The mandatory lead-in and lead-out for each session does waste space on the disc. In fact, 48 sessions would literally use up all of a 74-minute disc even with no data recorded in each session! Therefore, the practical limit for the number of sessions you can record on a disc would be much less than that.

CD-DA and older CD-ROM drives couldn't read more than one session on a disc, so that is the way most pressed CDs are recorded. The Orange Book allows multiple sessions on a single disc. To allow this, the Orange Book defines three main methods or modes of recording:

- Disk-at-Once (DAO)
- Track-at-Once (TAO)
- Packet writing

Disc-at-Once

Disc-at-Once means pretty much what it says: It is a single- session method of writing CDs in which the lead-in, data tracks, and lead-out are written in a single operation without ever turning off the writing laser, and the disc is closed. A disc is considered closed when the last (or only) lead-in is fully written and the next usable address on the disc is not recorded in that lead-in. In that case, the CD recorder is incapable of writing any further data on the disc. Note that it is not necessary to close a disc to read it in a normal CD-ROM drive, although if you were submitting a disc to a CD duplicating company for replication, most require that it be closed.

Track-at-Once

Multisession discs can be recorded in either Track-at-Once (TAO) or Packet writing mode. In Track-at-Once recording, each track can be individually written (laser turned on and off) within a session, until the session is closed. Closing a session is the act of writing the lead-out for that session, which means no more tracks can be added to that session. If the disc is closed at the same time, no further sessions can be added either.

The tracks recorded in TAO mode are divided by gaps of normally 2 seconds. Each track written has 150 sectors of overhead for run-in, run-out, pre-gap, and linking. A CD-R/RW drive can read the tracks even if the session is not closed, but to read them in a CD-DA or CD-ROM drive, the session must be closed. If you intend to write more sessions to the disc, you can close the session and not close the disc. At that point, you could start another session of recording to add more tracks to the disc. The main thing to remember is that each session must be closed (lead-out written) before another session can be written or before a normal CD-DA or CD-ROM drive can read the tracks in the session.

Packet Writing

Packetwriting is a method whereby multiple writes are allowed within a track, thus reducing the overhead and wasted space on a disc. Each packet uses 4 sectors for run-in, 2 for run-out, and 1 for linking. Packets can be of fixed or variable length, but most drives and packet-writing software uses a fixed length because it is much easier and more efficient to deal with file systems that way.

With packet writing, you normally use the Universal Disk Format (UDF) file system, which enables the CD to be treated essentially like a big floppy drive. That is, you can literally drag and drop files to it, use the copy command to copy files onto the disc, and so on. The packet-writing software and UDF file system manage everything. If the disc you are using for packet writing is a CD-R, every time a file is overwritten or deleted, the file seems to dissapear, but you don’t get the space back on the disc. Instead the file system simply forgets about the file. If the disc is a CD-RW, the space is indeed reclaimed and the disc won’t be full until you literally have more than the limit of active files stored there.

Unfortunately, Windows versions up through Windows 2000 don’t support packet writing or the UDF file system directly, so drivers must be loaded. Fortunately, though, these typically are included with CD-R/RW drives. One of the most popular packet-writing programs is DirectCD from Roxio (Adaptec).

When you remove a packet-written disc from the drive, the packet-writing software first asks whether you want the files to be visible to normal CD-ROM drives. If you do then the session must be closed. Even if the session is closed, you can still write more to the disc later, but there is an overhead of wasted space every time you close a session. If you are going to read the disc in a CD-R/RW drive, you don’t have to close the session because they will be capable of reading the files even if the session isn’t closed.

PhotoCD

First announced back in 1990 but not available until 1992, PhotoCD is a standard for CD-R discs and drives to store photos. You simply drop off a roll of film at a participating Kodak developer, and they digitize and store the photos on a specially formatted CD-R disc called a PhotoCD, which you can then read on virtually any CD-ROM drive connected to a PC running the appropriate software. Originally, Kodak sold PhotoCD "players" designed to display the photos to a connected TV, but these have since been dropped in favor of simply using a PC with software to decode and display the photos.

Perhaps the main benefit PhotoCD has brought to the table is that it was the first CD format to use the Orange Book Part II (CD-R) specification with multisession recordings. Additionally, the data is recorded in CD-ROM XA Mode 2, Form 2 sectors so more photo information could be stored on the disc.

Using the PhotoCD software, you can view your photographs at any one of several resolutions and manipulate them using standard graphics software packages.

When you drop off your roll of film, the Kodak developers produce prints as they normally do. After prints are made, they scan the prints with ultra–high-resolution scanners. To give you an idea of the amount of information each scan carries, one color photograph can take 15MB–20MB of storage. The compressed, stored images are then encoded onto special writable CDs. The finished product is packaged and shipped back to your local developer for pickup. Some developers can do the scanning on-site.

PhotoCD Disc Types

The images on the disc are compressed and stored using Kodak's own PhotoYCC encoding format, which includes up to six resolutions for each image, as shown in Table 13.15. Kodak has defined several types of PhotoCD discs to accommodate the needs of various types of users. The PhotoCD Master disc is the standard consumer format and contains up to 100 photos in all the resolutions shown in the table except for base x64.

Table 13.15 PhotoCD Resolutions

Base	Resolution (pixels)	Description
/16	128×192	Thumbnail
/4	256×384	Thumbnail
x1	512×768	TV resolution
x4	1,024×1,536	HDTV resolution
x16	2,048×3,072	Print size
x64	4,096×6,144	Pro PhotoCD master only

The various resolutions supply you with images appropriate for various applications. If, for example, you want to include a PhotoCD image on a Web page, you would choose a low-resolution image. A professional photographer shooting photos for a print ad would want to use the highest resolution possible.

The Pro PhotoCD Master disc is intended for professional photographers using larger film formats, such as 70mm, 120mm, or 4×5 inch. This type of disc adds an even higher-resolution image (4,096×6,144 pixels) to those already furnished on the PhotoCD Master disc. Because of this added high-resolution image, this type of disc can hold anywhere from 25 to 100 images, depending on the film format.

The PhotoCD Portfolio disc is designed for interactive presentations that include sound and other multimedia content. The high-resolution images that take up the most space are not necessary here, so this type of disc can contain up to 700 images, depending on how much other content is included.

Multisession Photo CDs

One breakthrough of the PhotoCD concept is that each of the disc types is capable of containing multiple sessions. Because the average consumer wouldn't usually have enough film processed to fill an entire disc, you can bring back your partially filled CDs each time you have more film to develop. A new session is then added to your existing CD until the entire disc is filled. You pay less for the processing because a new CD is not necessary, and all your images are stored on a smaller number of discs.

Any XA-compliant or XA-ready CD-ROM drive can read the multiple sessions on a PhotoCD disc, and even if your drive is not multisession capable, it can still read the first session on the disc. If this is the case, you must purchase a new disc for each batch of film you process, but you can still take advantage of PhotoCD technology.

Kodak provides software that enables you to view the PhotoCD images on your PC and licenses a PhotoCD import filter to the manufacturers of many desktop publishing, image-editing, and paint programs. Therefore, you can modify your PhotoCD images using a program such as Adobe Photoshop and integrate them into documents for printing or electronic publication with a page layout program such as Adobe PageMaker.

Picture CD

Although Kodak still offers PhotoCD services, the high cost has led to limited popularity. Kodak now offers the simpler Picture CD and Picture Disk services. Unlike PhotoCD, these services use the industry-standard JPEG file format. Picture CD uses a CD-R, with images stored at a single medium-resolution scan of 1,024×1,536 pixels. This resolution is adequate for 4”×6” and 5”×7” prints. The less-expensive Picture Disk service stores images on a 1.44MB floppy disk at a resolution of 400×600, suitable for screensavers and slide shows.

The software provided with Picture CD enables the user to manipulate images with various automatic or semiautomatic operations, but unlike PhotoCD, the standard JPEG (JPG) file format used for storage enables any popular image-editing program to work with the images without conversion. Although the image quality of Picture CD isn't as high as with PhotoCD, the much lower price of the service should make it far more popular with amateur photographers.

White Book—Video CD

The White Book was introduced in 1993 by Philips, JVC, Matsushita, and Sony. It is based on the Green Book (CD-i) and CD-ROM XA standards and allows for storing up to 74 minutes of MPEG-1 video and ADPCM digital audio data on a single disc. The latest version was released in April 1995.

You can think of video CDs as a sort of poor man's DVD format, although the picture and sound quality is actually quite good—certainly better than VHS or most other videotape formats. You can play video CDs on virtually any PC with a CD-ROM drive using the free Windows Media Player (other media player applications can be used as well). They also can be played on most DVD players and even some game consoles, such as the Playstation (with the right options). Video CDs are an especially big hit with people who travel with laptop computers, and the prerecorded discs are much cheaper than DVD—many as little as $5.

Blue Book—CD EXTRA

Manufacturers of CD-DA media were looking for a standard method to combine both music and data on a single CD. The intention was for a user to be able to play only the audio tracks in a standard audio CD player while remaining unaware of the data track. However, a user with a PC or a dedicated combination audio/data player could access both the audio and data tracks on the same disc.

The fundamental problem with nonstandard mixed-mode CDs is that if or when an audio player tries to play the data track, the result is static that could conceivably damage speakers and possibly hearing if the volume level has been turned up. Various manufacturers originally addressed this problem in different ways, resulting in a number of confusing methods for creating these types of discs, some of which still allowed the data tracks to be accidentally "played" on an audio player.

In 1995, Philips and Sony developed the CD EXTRA specification, as defined in the Blue Book standard. CDs conforming to this specification usually are refered to as CD EXTRA (formerly called CD Plus or CD Enhanced Music) discs and use the multisession technology defined in the CD-ROM XA standard to separate the audio and data tracks. These are a form of stamped multisession disc. The audio portion of the disc can consist of up to 98 standard Red Book audio tracks, whereas the data track typically is composed of XA Mode 2 sectors and can contain video, song lyrics, still images, or other multimedia content. Such discs can be identified by the CD EXTRA logo, which is the standard CD-DA logo with a plus sign to the right. Often the logo or markings on the disc package are overlooked or somewhat obscure, and you might not know that an audio CD contains this extra data until you play it in a CD-ROM drive.

A CD EXTRA disc normally contains two sessions. Because audio CD players are only single-session capable, they play only the audio session and ignore the additional session containing the data. A CD-ROM drive in a PC, however, can see both sessions on the disc and access both the audio and data tracks.

Note

Many artists have released audio CDs in the CD EXTRA format that include things such as lyrics, video, artist bio, photos, and so on in data files on the disc. *Tidal* by Fiona Apple (released in 1996) was one of the first CD EXTRA discs from Sony Music. There have been many CD EXTRA releases since then. For examples of other CD EXTRA discs, including current releases, see `http://www.cdextra.com`.

CD-ROM File Systems

Manufacturers of early CD-ROM discs required their own custom software to read the discs. This is because the Yellow Book specification for CD-ROM details only how data sectors—rather than audio sectors—can be stored on a disc, and did not cover the file systems or deal with how data should be stored in files and how these should be formatted for use by PCs with different operating systems. Obviously, noninterchangeable file formats presented an obstacle to the industrywide compatiblity for CD-ROM applications.

In 1985–1986, several companies got together and published the High Sierra file format specification, which finally enabled CD-ROMs for PCs to be universally readable. That was the first industry-standard CD-ROM file system that made CD-ROMs universally usable in PCs. Today several file systems are used on CDs, including

- High Sierra
- ISO 9660 (based on High Sierra)
- Joliet
- UDF (Universal Disk Format)
- Mac HFS (Hierarchical File Format)
- Rock Ridge

Not all CD file system formats can be read by all operating systems. Table 13.17 shows the primary file systems used and which operating systems support them.

Table 13.16 CD File System Formats

CD File System	DOS/Win 3.1	Win 9x/Me	Win NT/2000	Mac OS
High Sierra	Yes	Yes	Yes	Yes
ISO 9660	Yes	Yes	Yes	Yes
Joliet	Yes[1]	Yes	Yes	Yes[1]
UDF	No	Yes[2]	Yes[2]	Yes[2]

1. A short name, such as (SHORTN~1.TXT), is shown.

2. Only if a UDF driver is installed.

Note

The Mac HFS and Rock Ridge file systems are not supported by PC operating systems such as DOS or Windows and therefore are not covered in depth here.

High Sierra

To make CD-ROM discs readable on all systems without having to develop custom file systems and drivers, it was in the best interests of all PC hardware and software manufacturers to resolve the CD-ROM file format standardization issue. In 1985, representatives from TMS, DEC, Microsoft, Hitachi, LaserData, Sony, Apple, Philips, 3M, Video Tools, Reference Technology, and Xebec met at what was then called the High Sierra Hotel and Casino in Lake Tahoe, Nevada, to create a common logical format and file structure for CD-ROMs. In 1986, they jointly published this standard as the "Working Paper for Information Processing: Volume and File Structure of CD-ROM Optical Discs for Information Exchange (1986)." This standard was subsequently referred to as the High Sierra format.

This agreement enabled all drives using the appropriate driver (such as MSCDEX.EXE supplied by Microsoft with DOS) to read all High Sierra format discs, opening the way for the mass production and acceptance of CD-ROM software publishing. Adoption of this standard also enabled disc publishers to provide cross-platform support for their software, easily manufacturing discs for DOS, Unix, and other operating system formats. Without this agreement, the maturation of the CD-ROM marketplace would have taken years longer and the production of CD-ROM–based information would have been stifled.

The High Sierra format was submitted to the International Organization for Standardization (ISO), and two years later (in 1988) and with several enhancements and changes it was republished as the ISO 9660 standard. ISO 9660 was not exactly the same as High Sierra, but all the drivers that would read High Sierra–formatted discs were quickly updated to handle both ISO 9660 and the original High Sierra format on which it was based.

For example, Microsoft wrote the MSCDEX.EXE (Microsoft CD-ROM extensions) driver in 1988 and licensed it to CD-ROM hardware and software vendors to include with their products. It wasn't until 1993 when MS-DOS 6.0 was released that MSCDEX was included with DOS as a standard feature. MSCDEX enables DOS to read ISO 9660–formatted (and High Sierra–formatted) discs. This driver works with the AT Attachment Packet Interface (ATAPI) or Advanced SCSI Programming Interface (ASPI) hardware-level device driver that comes with the drive. Microsoft built ISO 9660 and Joliet file system support directly into Windows 95 and later, with no additional drivers necessary.

ISO 9660

The ISO 9660 standard enabled full cross compatibility among different computer and operating systems. ISO 9660 was released in 1988 and was based on the work done by the High Sierra group.

Although based on High Sierra, ISO 9660 does have some differences and refinements. But any drivers that can read ISO 9660 also can read discs formatted in High Sierra. ISO 9660 has three levels of interchange that dictate the features that can be used to ensure compatibility with different systems.

ISO 9660 Level 1 is the lowest common denominator of all CD file systems and is capable of being read by almost every computer platform, including Unix and Macintosh. The downside of this file system is that it is very limited with respect to filenames and directories. Level 1 interchange restrictions include

- Only uppercase characters A–Z, numbers 0–9, and the underscore (_) are allowed in filenames.
- 8.3 characters maximum for the name.extension (based on DOS limits).
- Directory names are eight characters maximum (no extension allowed).
- Directories are limited to eight levels deep.
- Files must be contiguous.

Level 2 interchange rules have the same limitations as Level 1, except that the filename and extension can be up to 30 characters long (both added together, not including the . separator). Finally, Level 3 interchange rules are the same as Level 2 except that files don't have to be contiguous.

Note that Windows 95 and later versions enable you to use file and folder names up to 255 characters long, which can include spaces as well lowercase and many other characters not allowed in ISO 9660. To maintain backward compatiblity with DOS, Win95 and later associate a short 8.3 format filename as an alias for each file that has a longer name. These alias short names are created automatically by Windows and can be viewed in the Properties for each file or by using the `DIR` command at a command prompt. To create these alias names, Windows truncates the name to six (or fewer) characters followed by a tilde (~) and a number starting with 1 and truncates the extension to three characters. Other numbers are used in the first part if other files that would have the same alias when truncated already exist. For example, the filename `This is a.test` gets `THISIS~1.TES` as an alias.

This filename alias creation is independent of your CD drive, but it is important to know that if you create or write to a CD using the ISO 9660 format using Level 1 restrictions, the alias short names are used when recording files to the disc, meaning any long filenames will be lost in the process. In fact, even the alias short name will be modified because ISO 9660 Level 1 restrictions don't allow a tilde—that character is converted to an underscore in the names written to the CD.

The ISO 9660 data starts at 2 seconds and 16 sectors into the disc, which is also known as *logical sector 16 of track one*. For a multisession disc, the ISO 9660 data is present in the first data track of each session containing CD-ROM tracks. This data identifies the location of the volume area—where the actual data is stored. The system area also lists the directories in this volume as the volume table of contents (VTOC), with pointers or addresses to various named areas, as illustrated in Figure 13.6. A significant difference between the CD directory structure and that of a normal hard disk is that the CD's system area also contains direct addresses of the files within the subdirectories, allowing the CD to seek specific sector locations on the spiral data track. Because the CD data is all on one long spiral track, when speaking of tracks in the context of a CD, we're actually talking about sectors or segments of data along that spiral.

To put the ISO 9660 format in perspective, the disc layout is roughly analogous to that of a floppy disk. A floppy disk has a system track that not only identifies itself as a floppy disk and reveals its density and operating system, but also tells the computer how it's organized—into directories, which are made up of files.

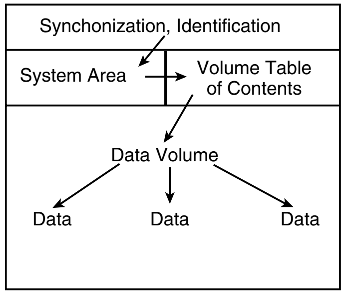

Figure 13.6 A diagram of basic ISO 9660 file organizational format.

Joliet

Joliet is an extension of the ISO 9660 standard developed by Microsoft for use with Windows 95 and later. Joliet enables CDs to be recorded using filenames up to 64 characters long, including spaces and other characters from the Unicode international character set. Joliet also preserves an 8.3 alias for those programs that can't use the longer filenames.

In general, Joliet features the followig specifications:

- File or directory names can be up to 64 Unicode characters (128 bytes) in length.
- Directory names can have extensions.
- Directories can be deeper than eight levels.
- Multisession recording is inherently supported.

Due to backward-compatibility provisions, systems that don't support the Joliet extensions (such as older DOS systems) should still be capable of reading the disc. However, it will be interpreted as an ISO 9660 format using the short names instead.

Note

A bit of trivia: "Chicago" was the code name used by Microsoft for Windows 95. Joliet is the town outside of Chicago where Jake was locked up in the movie *The Blues Brothers*.

Universal Disk Format

UDF is a relatively new file system created by the Optical Storage Technology Association (OSTA) as an industry-standard format for use on optical media such as CD-ROM and DVD. UDF has several advantages over the ISO 9660 file system used by standard CD-ROMs but is most noted because it is designed to work with packet writing, a technique for writing small amounts of data to a CD-R/RW disc, treating it much like a standard magnetic drive.

The UDF file system allows long filenames up to 255 characters per name. There have been several versions of UDF, with most packet-writing software using UDF 1.5 or later. Packet-writing software such as DirectCD from Roxio writes in the UDF file system. Standard CD-ROM drives, drivers, or operating systems such as DOS can't read UDF formatted discs. Recordable drives can read them, but regular CD-ROM drives must conform to the MultiRead specification (see the section "MultiRead Specifications," later in this chapter) to be capable of reading UDF discs.

After you are sure that your drive can read UDF, you must check the OS. Most operating systems can't read UDF natively—the support has to be added via a driver. DOS can't read UDF at all; however, with Windows 95 and later, UDF-formatted discs can be read by installing a UDF driver. Normally such a driver is included with the software that is included with most CD-RW drives. If you don't have a UDF driver, you can download one for free from Roxio at `http://www.roxio.com`. The Roxio UDF Reader is included with DirectCD 3.0 and later. After the UDF driver is installed, you do not need to take any special steps to read a UDF-formatted disc. The driver will be in the background waiting for you to insert a UDF-formatted disc.

You can close a DirectCD for Windows disc to make it readable in a normal CD-ROM drive, which will convert the filenames to Joliet format, causing them to be truncated to 64 characters.

Macintosh HFS

HFS is the file system used by the Macintosh OS. HFS can also be used on CD-ROMs; however if that is done, they will not be readable on a PC. A hybrid disc can be produced with both Joliet and HFS or ISO 9660 and HFS file systems, and the disc would then be readable on both PCs and Macs. In that case, the system will see only the disc that is compatible, which is ISO 9660 or Joliet in the case of PCs.

Rock Ridge

The Rock Ridge Interchange Protocol (RRIP) was developed by an industry consortium called the Rock Ridge group. It was officially released in 1994 by the IEEE CD-ROM File System Format Working Group and specifies an extension to the ISO 9660 standard for CD-ROM that enables the recording of additional information to support Unix/POSIX file system features. Rock Ridge is not supported by DOS or Windows. However, because it is based on ISO 9660, the files are still readable on a PC and the RRIP extensions are simply ignored.

Note

An interesting bit of trivia is that the Rock Ridge name was taken from the fictional Western town in the movie *Blazing Saddles*.

DVD

DVD stands for digital versatile disc and in simplest terms is a high-capacity CD. In fact, every DVD-ROM drive *is* a CD-ROM drive; that is, they can read CDs as well as DVDs (discs). DVD uses the same optical technology as CD, with the main difference being higher density. The DVD standard dramatically increases the storage capacity of, and therefore the useful applications for, CD-ROM–sized discs. A CD-ROM can hold a maximum of about 737MB (80-minute disc) of data, which might sound like a lot but is simply not enough for many up-and-coming applications, especially where the use of video is concerned. DVD discs, on the other hand, can hold up to 4.7GB (single layer) or 8.5GB (dual layer) on a single side of the disc, which is more than 11 1/2 times greater than a CD. Double-sided DVD discs can hold up to twice that amount; although currently you must manually flip the disc over to read the other side.

Up to two layers of information can be recorded to DVD discs, with an initial storage capacity of 4.7GB of digital information on a single-sided, single-layer disc—a disk that is the same overall diameter and thickness of a current CD-ROM. With Moving Picture Experts Group–standard 2 (MPEG-2) compression, that's enough to contain approximately 133 minutes of video, which is enough for a full-length, full-screen, full-motion feature film—including three channels of CD-quality audio and four channels of subtitles. Using both layers, a single-sided disc could easily hold 240 minutes of video or more. This initial capacity is no coincidence; the creation of DVD was driven by the film industry, which has long sought a storage medium cheaper and more durable than videotape.

Note

It is important to know the difference between the DVD-Video and DVD-ROM standards. DVD-Video discs contain only video programs and are intended to be played in a DVD player, connected to a television and possibly an audio system. DVD-ROM is a data storage medium intended for use by PCs and other types of computers. The distinction is similar to that between an audio CD and a CD-ROM. Computers might be capable of playing audio CDs as well as CD-ROMs, but dedicated audio CD players can't use a CD-ROM's data tracks. Likewise, computer DVD drives can play DVD-video discs (with MPEG-2 decoding in either hardware or software), but DVD video players can't access data on a DVD-ROM.

The initial application for DVDs was as an upgrade for CDs as well as a replacement for prerecorded videotapes. DVDs can be rented or purchased like prerecorded VCR tapes, but they offer much higher resolution and quality with greater content. As with CDs, which initially were designed only for music, DVDs have since developed into a wider range of uses, including computer data storage.

DVD History

DVD had a somewhat rocky start. During 1995, two competing standards for high-capacity CD-ROM drives were being developed to compete with each other for future market share. One standard, called Multimedia CD, was introduced and backed by Philips and Sony, whereas a competing standard, called the Super Density (SD) disk, was introduced and backed by Toshiba, Time Warner, and several other companies. If both standards had hit the market as is, consumers as well as entertainment and software producers would have been in a quandary over which one to choose.

Fearing a repeat of the Beta/VHS situation that occured in the videotape market, several organizations, including the Hollywood Video Disc Advisory Group and the Computer Industry Technical Working Group, banded together to form a consortium to develop and control the DVD standard. The consortium insisted on a single format for the industry and refused to endorse either competing proposal. With this incentive, both groups worked out an agreement on a single, new, high-capacity CD type disc in September of 1995. The new standard combined elements of both previously proposed standards and was called DVD, which originally stood for digital video disc, but has since been changed to digital versatile disc. The single DVD standard has avoided a confusing replay of the VHS versus Beta tape fiasco and has given the software, hardware, and movie industries a single, unified standard to support.

After agreeing on copy protection and other items, the DVD-ROM and DVD-Video standards were officially announced in late 1996. Players, drives, and discs were announced in January 1997 at the Consumer Electronics Show (CES) in Las Vegas, and the players and discs became available in March of 1997. The initial players were about $1,000 each. Only 36 movies were released in the first wave, and they were available only in seven cities nationwide (Chicago, Dallas, Los Angeles, New York, San Francisco, Seattle, and Washington, D.C.) until August 1997 when the full release began. After a somewhat rocky start (much had to do with agreements on copy protection to get the movie companies to go along, and there was a lack of titles available in the beginning), DVD has become an incredible success. It will likely continue to grow after the rewritable +RW format becomes available in 2001 and changes DVD from a read-only to a fully rewritable consumer as well as computer device.

The organization that controls the DVD standard is called the DVD Forum and was founded by 10 companies, including Hitachi, Matsushita, Mitsubishi, Victor, Pioneer, Sony, Toshiba, Philips, Thomson, and Time Warner. Since its founding in 1995, more than 230 companies have joined the forum. Because it is a public forum, anybody can join and attend the meetings; the site for the DVD forum is `http://www.dvdforum.org`.

DVD Technology

DVD technology is similar to CD technology. Both use the same size (120mm diameter, 1.2mm thick, with a 15mm hole in the center) discs with pits and lands stamped in a polycarbonate base. Unlike a CD, though, DVDs can have two layers of recordings on a side and be double-sided as well. Each layer is separately stamped, and they are all bonded together to make the final 1.2mm-thick disc. The manufacturing process is largely the same, with the exception that each layer on each side is stamped from a separate piece of polycarbonate plastic and are then bonded together to form the completed disc. The main difference between CD and DVD is that DVD is a higher-density recording read by a laser with a shorter wavelength, which enables more information to be stored. Also, whereas CDs are single-sided and have only one layer of stamped pits and lands, DVDs can have up to two layers per side and can have information on both sides.

As with CDs, each layer is stamped or molded with a single physical track in a spiral configuration starting from the inside of the disc and spiraling outward. The disc rotates counterclockwise (as viewed from the bottom), and each spiral track contains pits (bumps) and lands (flat portions) just as on a CD. Each recorded layer is coated with a thin film of metal to reflect the laser light. The outer layer has a thinner coating to allow the light to pass through to read the inner layer. If the disc is single-sided, a label can be placed on top; otherwise, if it's double-sided, only a small ring near the center provides room for labeling.

Reading the information back is a matter of bouncing a low-powered laser beam off one of the reflective layers in the disc. The laser shines a focused beam on the underside of the disc, and a photosensitive receptor detects when the light is reflected back. When the light hits a land (flat spot) on the track, the light is reflected back; when the light hits a pit (raised bump), no light is reflected back.

As the disc rotates over the laser and receptor, the laser shines continuously while the receptor sees what is essentially a pattern of flashing light as the laser passes over pits and lands. Each time the laser passes over the edge of a pit the light seen by the receptor changes in state from being reflected to not reflected or vice versa. Each change in state of reflection caused by crossing the edge of a pit is translated into a 1 bit digitally. Microprocessors in the drive translate the light/dark and dark/light (pit edge) transitions into 1 bits, translate areas where there are no transitions into 0 bits, and then translate the bit patterns into actual data or sound.

The individual pits on a DVD are 0.105 microns deep and 0.4 microns wide. Both the pits and lands vary in length from about 0.4 microns at their shortest to about 1.9 microns at their longest (on single-layer discs).

See the section "CD-ROM Technology" earlier in this chapter for more information on how the pits and lands are read and converted into actual data, as well as how the drives physically and mechanically work.

DVD uses the same optical laser read pit and land storage that CDs do. The greater capacity is made possible by several factors, including the following:

- A 2.25 times smaller pit length (0.9–0.4 microns)
- A 2.16 times reduced track pitch (1.6–0.74 microns)
- A slightly larger data area on the disc (8,605–8,759 square millimeters)
- About 1.06 times more efficient channel bit modulation
- About 1.32 times more efficient error correction code
- About 1.06 times less sector overhead (2,048/2,352–2,048/2,064 bytes)

The DVD disc's pits and lands are much smaller and closer together than those on a CD, allowing the same physical-sized platter to hold much more information. Figure 13.7 shows how the grooved tracks with pits and lands are just over four times as dense on a DVD as compared to a CD.

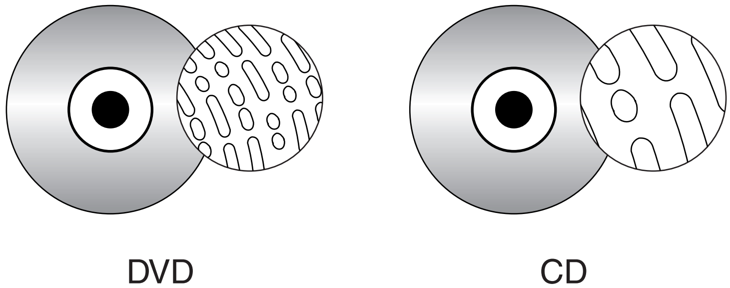

Figure 13.7 DVD data markings (pits and lands) versus those of a standard CD.

DVD drives use a shorter wavelength laser to read these smaller pits and lands. DVD can have nearly double the initial capacity by using two separate layers on one side of a disc and double it again by using both sides of the disc. The second data layer is written to a separate substrate below the first layer, which is then made semireflective to enable the laser to penetrate to the substrate beneath it. By focusing the laser on one of the two layers, the drive can read roughly twice the amount of data from the same surface area.

DVD Tracks and Sectors

The pits are stamped into a single spiral track (per layer) with a spacing of 0.74 microns between turns, corresponding to a track density of 1,351 turns per millimeter or 34,324 turns per inch. This equates to a total of 49,324 turns and a total track length of 11.8km or 7.35 miles in length. The track is comprised of sectors, with each sector containing 2,048 bytes of data. The disc is divided into four main areas:

- *Hub clamping area.* The hub clamp area is just that, a part of the disc where the hub mechanism in the drive can grip the disc. No data or information is stored in that area.
- *Lead-in zone.* The lead-in zone contains buffer zones, reference code, and mainly a control data zone with information about the disc. The control data zone consists of 16 sectors of information repeated 192 times for a total of 3,072 sectors. Contained in the 16 (repeated) sectors is information about the disc, including disc category and version number, disc size and maximum transfer rate, disc structure, recording density, and data zone allocation. The entire lead-in zone takes up to 196,607 (2FFFFh) sectors on the disc. Unlike CDs, the basic structure of all sectors on a DVD are the same. The buffer zone sectors in the lead-in zone have all 00h (zero hex) recorded for data.
- *Data zone.* The data zone contains the video, audio, or other data on the disc and starts at sector number 196,608 (30000h). The total number of sectors in the data zone can be up to 2,292,897 per layer for single layer discs.
- *Lead-out (or middle) zone.* The lead-out zone marks the end of the data zone. The sectors in the lead-out zone all contain zero (00h) for data. This is called the middle zone if the disc is dual layer and is recorded in opposite track path (OPT) mode, in which the second layer starts from the outside of the disc and is read in the opposite direction from the first layer.

The center hole in a DVD is 15mm in diameter, so it has a radius of 7.5mm from the center of the disc. From the edge of the center hole to a point at a radius of 16.5mm is the hub clamp area. The lead-in zone starts at a radius of 22mm from the center of the disc. The data zone starts at a radius of 24mm from the center and is followed by the lead-out (or middle) zone at 58mm. The disc track officially ends at 58.5mm, which is followed by a 1.5mm blank area to the edge of the disc. Figure 13.8 shows these zones in actual relative scale as they appear on a DVD.

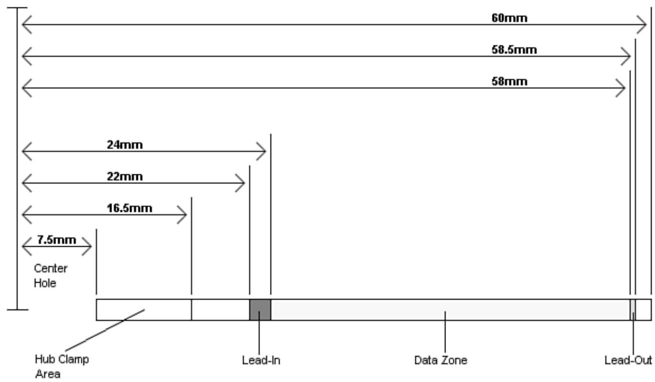

Figure 13.8 Areas on a DVD (side view).

Officially, the spiral track of a standard DVD starts with the lead-in zone and ends at the finish of the lead-out zone. This single spiral track is about 11.84 kilometers or 7.35 miles long. An interesting fact is that in a 20x CAV drive, when reading the outer part of the track, the data moves at an actual speed of 156 miles per hour (251km/h) past the laser. What is more amazing is that even when the data is traveling at that speed, the laser pickup can accurately read bits (pit/land transitions) spaced as little as only 0.4 microns or 15.75 millionths of an inch apart!

DVDs come in both single- and dual-layer as well as single- and double-sided versions. The double-sided discs are essentially the same as two single-sided discs glued together back to back, but subtle differences do exist between the single- and dual-layer discs. Table 13.17 shows some of the basic information about DVD technology, including single- and dual-layer DVDs. The dual-layer versions are recorded with slightly longer pits, resulting in slightly less information being stored in each layer.

Table 13.17 DVD Technical Parameters

DVD Type:	Single-Layer	Dual-Layer
1x read speed (m/sec)	3.49	3.84
Laser wavelength (nm)	650	650
Media refractive index	1.55	1.55
Track (turn) spacing (um)	0.74	0.74
Turns per mm	1,351	1,351
Turns per inch	34,324	34,324
Total track length (m)	11,836	11,836
Total track length (feet)	38,832	38,832
Total track length (miles)	7.35	7.35

Table 13.17 Continued

Media bit cell length (nm)	133.3	146.7
Media byte length (um)	1.07	1.17
Media sector length (mm)	5.16	5.68
Pit width (um)	0.40	0.40
Pit depth (um)	0.105	0.105
Min. nominal pit length (um)	0.40	0.44
Max. nominal pit length (um)	1.87	2.05
Lead-in inner radius (mm)	22	22
Data zone inner radius (mm)	24	24
Data zone outer radius (mm)	58	58
Lead-out outer radius (mm)	58.5	58.5
Data zone width (mm)	34	34
Data zone area (mm2)	8,759	8,759
Total track area width (mm)	36.5	36.5
Max. rotating speed 1x CLV (rpm)	1,515	1,667
Min. rotating speed 1x CLV (rpm)	570	627
Track revolutions (data zone)	45,946	45,946
Track revolutions (total)	49,324	49,324
Data zone sectors per layer per side	2,292,897	2,083,909
Sectors per second	676	676
Media data rate (mbits/sec)	26.15625	26.15625
Media bits per sector	38,688	38,688
Media bytes per sector	4,836	4,836
Interface data Rate (mbits/sec)	11.08	11.08
Interface data bits per sector	16,384	16,384
Interface data bytes per sector	2,048	2,048
Track time per layer (minutes)	56.52	51.37
Track time per side (minutes)	56.52	102.74
MPEG-2 video per layer (minutes)	133	121
MPEG-2 video per side (minutes)	133	242

B = Byte (8 bits)
KB = Kilobyte (1,000 bytes)
KiB = Kibibyte (1,024 bytes)
MB = Megabyte (1,000,000 bytes)
MiB = Mebibyte (1,048,576 bytes)
GB = Gigabyte (1,000,000,000 bytes)
GiB = Gibibyte (1,073,741,824 bytes)
m = meters
mm = millimeters (thousandths of a meter)
mm2 = square millimeters
um = micrometers = microns (millionths of a meter)
nm = nanometers (billionths of a meter)
rpm = revolutions per minute
ECC = Error correction code
EDC = Error detection code
CLV = Constant linear velocity
CAV = Constant angular velocity

As you can see from the information in Table 13.17, the spiral track is divided into sectors that are stored at the rate of 676 sectors per second. Each sector contains 2,048 bytes of data.

When being written, the sectors are first formatted into data frames of 2,064 bytes, of which 2,048 are data, 4 bytes contain ID information, 2 bytes contain ID error detection (IED) codes, 6 bytes contain copyright information, and 4 bytes contain EDC for the frame.

The data frames then have ECC information added to convert them into ECC frames. Each ECC frame contains the 2,064-byte data frame plus 182 parity outer (PO) bytes and 120 parity inner (PI) bytes, for a total of 2,366 bytes for each ECC frame.

Finally, the ECC frames are converted into physical sectors on the disc. This is done by taking 91 bytes at a time from the ECC frame and converting them into recorded bits via 8 to 16 modulation. This is where each byte (8 bits) is converted into a special 16-bit value, which is selected from a table. These values are designed using an RLL 2,10 scheme, which is designed so that the encoded information never has a run of less than 2 or more than 10 0 bits in a row. After each group of 91 bytes is converted via the 8 to 16 modulation, 320 bits (4 bytes) of synchronization information is added. After the entire ECC frame is converted into a physical sector, 4,836 total bytes are stored.

Table 13.18 shows the sector, frame, and audio data calculations.

Table 13.18 DVD Data Frame, ECC Frame, and Physical Sector Layout and Information

DVD Data Frame:	
Identification data (ID) bytes	4
ID Error detection code (IED) bytes	2

Unlike CDs, DVDs do not use subcodes and instead use the ID bytes in each data frame to store the sector number and information about the sectors.

Handling Errors

DVDs use more powerful error correcting codes than were first devised for CDs. Unlike CDs, which have different levels of error correction depending on whether audio/video or data is being stored, DVDs treat all information equally and apply the full error correction to all sectors.

The main error correcting in DVDs takes place in the ECC frame. Parity outer (column) and parity inner (row) bits are added to detect and correct errors. The scheme is simple and yet very effective. The information from the data frames is first broken up into 192 rows of 172 bytes each. Then, a polynomial equation is used to calculate and add 10 PI bytes to each row, making the rows now 182 bytes each. Finally, another polynomial equation is used to calculate 16 PO (Parity Outer) bytes for each column, resulting in 16 bytes (rows) being added to each column. What started out as 192 rows of 172 bytes becomes 208 rows of 182 bytes with the PI and PO information added.

The function of the PI and PO bytes can be explained with a simple example using simple parity. In this example, 2 bytes are stored (01001110 = N, 01001111 = O). To add the error correcting information, they are organized in rows, as shown in the following:

```
          Data bits
          1 2 3 4 5 6 7 8
-------------------------------------
Byte 1    0 1 0 0 1 1 1 0
Byte 2    0 1 0 0 1 1 1 1
-------------------------------------
```

Then, 1 PI bit is added for each row, using odd parity. This means you count up the 1 bits: In the first row there are 4, so the parity bit is created as a 1, making the sum an odd number. In the second row, the parity bit is a 0 because the sum of the 1s was already an odd number. The result is as follows:

```
          Data bits        |
          1 2 3 4 5 6 7 8  |   PI
---------------------------------------|---------
Byte 1    0 1 0 0 1 1 1 0  |   1
Byte 2    0 1 0 0 1 1 1 1  |   0
---------------------------------------|---------
```

Next, the parity bits for each column are added and calculated the same as before. In other words, the parity bit will be such that the sum of the 1s in each column is an odd number. The result is as follows:

```
          Data bits        |
          1 2 3 4 5 6 7 8  |   PI
---------------------------------------|---------
Byte 1    0 1 0 0 1 1 1 0  |   1
Byte 2    0 1 0 0 1 1 1 1  |   0
---------------------------------------|---------
    PO    1 1 1 1 1 1 1 0  |   1
```

Now the code is complete, and the extra bits are stored along with the data. So, instead of just the 2 bytes being stored, 11 addition bits are stored for error correction. When the data is read back, the error correction bit calculations are repeated and they're checked to see whether they are the same as before. To see how it works, let's change one of the data bits (due to a read error) and recalculate the error correcting bits as follows:

```
          Data bits          |
          1 2 3 4 5 6 7 8    |   PI
-----------------------------|---------
Byte 1    0 1 0 0 1 0 1 0    |   0
Byte 2    0 1 0 0 1 1 1 1    |   0
-----------------------------|---------
   PO     1 1 1 1 1 0 1 0    |   1
```

Now, when you compare the PI and PO bits you calculated after reading the data to what was originally stored, you see a change in the PI bit for byte (row) 1 and in the PO bit for bit (column) 6. This identifies the precise row and column where the error was, which is at byte 1 (row 1), bit 6 (column 6). That bit was read as a 0, and you now know it is wrong, so it must have been a 1. The error correction circuitry then simply changes it back to a 1 before passing it back to the system. As you can see, with some extra information added to each row and column, error correction codes can indeed detect and correct errors on-the-fly.

Besides the ECC frames, DVDs also scramble the data in the frames using a bit-shift technique and also interleave parts of the ECC frames when they are actually recorded on the disc. These schemes serve to store the data somewhat out of sequence, preventing a scratch from corrupting consecutive pieces of data.

DVD Capacity (Sides and Layers)

Four main types of DVD discs are available, categorized by whether they are single- or double-sided, and single- or dual-layered. They are designated as follows:

- *DVD-5 - 4.7GB Single-Side, Single-Layer.* A DVD-5 is constructed from two substrates bonded together with adhesive. One is stamped with a recorded layer (called Layer 0), and the other is blank. An aluminum coating typically is applied to the single recorded layer.
- *DVD-9 - 8.5GB Single-Side, Dual-Layer.* A DVD-9 is constructed of two stamped substrates bonded together to form two recorded layers for one side of the disc, along with a blank substrate for the other side. The outer stamped layer (0) is coated with a semitransparent gold coating to both reflect light if the laser is focused on it and pass light if the laser is focused on the layer below. A single laser is used to read both layers; only the focus of the laser is changed.
- *DVD-10 - 9.4GB Double-Side, Single-Layer.* A DVD-10 is constructed of two stamped substrates bonded together back to back. The recorded layer (Layer 0 on each side) usually is coated with aluminum. Note that these discs are double-sided; however, drives have a read laser only on the bottom, which means the disc must be removed and flipped to read the other side.
- *DVD-18 - 17.1GBDouble-Side, Dual-Layer.* A DVD-18 combines both double layers and double sides. Two stamped layers form each side, and the substrate pairs are bonded back to back. The outer layers (Layer 0 on each side) are coated with semitransparent gold, whereas the inner layers (Layer 1 on each side) are coated with aluminum. The reflectivity of a single-layer disc is 45%–85%, and for a dual-layer disc the reflectivity is 18%–30%. The automatic gain control (AGC) circuitry in the drive compensates for the different reflective properties.

Figure 13.9 shows the construction of each of the DVD disc types.

Note that although Figure 13.9 shows two lasers reading the bottom of the dual-layer discs, in actual practice only one laser is used. Only the focus is changed to read the different layers.

Dual-layer discs can have the layers recorded in two ways: either OTP or parallel track path (PTP). OTP minimizes the time needed to switch from one layer to the other when reading the disc. When reaching the inside of the disc (end of Layer 0), the laser pickup remains in the same location—it merely moves towards the disc slightly to focus on Layer 1. When written in OTP mode, the lead-out zone toward the outer part of the disc is called a middle zone instead.

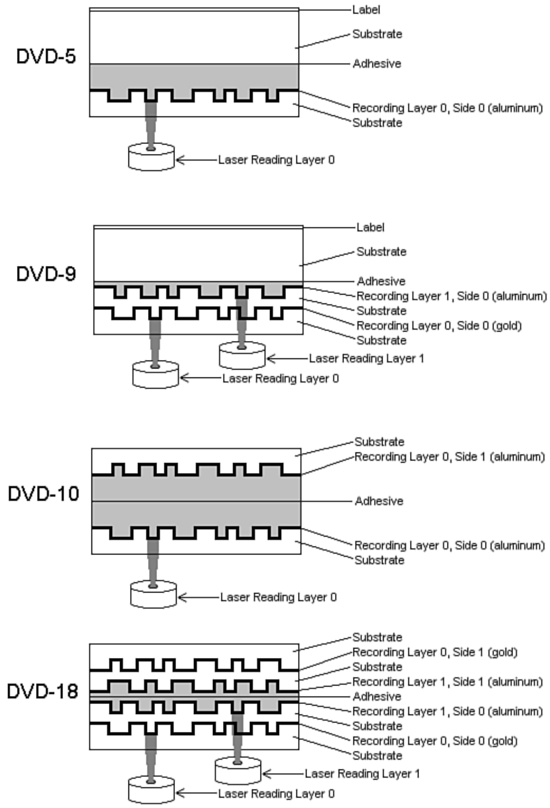

Figure 13.9 DVD disk types and construction.

Discs written in PTP have both spiral layers written (and read) from the inside out. When changing from Layer 0 to Layer 1, PTP discs require the laser pickup to move from the outside (end of the first layer) back to the inside (start of the second layer), as well as for the focus of the laser to change. Virtually all discs are written in OTP mode to make the layer change quicker.

To allow the layers to be read more easily even though they are on top of one another, discs written in PTP mode have the spiral direction changed from one layer to the other. Layer 0 has a spiral winding clockwise (which is read counterclockwise), whereas Layer 1 has a spiral winding counterclockwise. This typically requires that the drive spin the disc in the opposite direction to read that layer, but with OTP the spiral is read from the outside in on the second layer. So Layer 0 spirals from the inside out, and Layer 1 spirals from the outside in.

Figure 13.10 shows the differences between PTP and OTP on a DVD:

DVDs store up to 4.7GB–17.1 GB, depending on the type. Table 13.19 shows the precise capacities of the various types of DVDs.

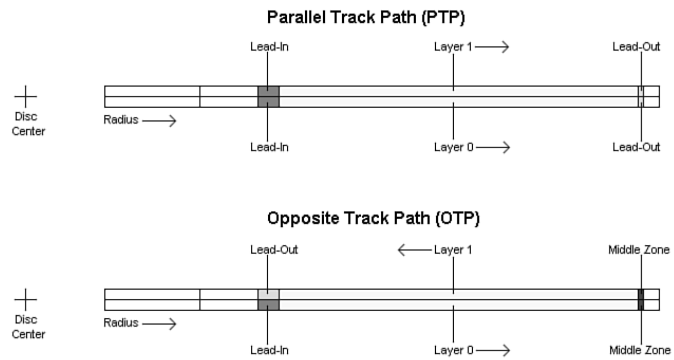

Figure 13.10 PTP versus OTP.

Table 13.19 Continued

MPEG-2 video (approx. minutes)	266	484
MPEG-2 video (hours:minutes)	4:26	8:04

B = Byte (8 bits)
KB = Kilobyte (1,000 bytes)
KiB = Kibibyte (1,024 bytes)
MB = Megabyte (1,000,000 bytes)
MiB = Mebibyte (1,048,576 bytes)
GB = Gigabyte (1,000,000,000 bytes)
GiB = Mebibyte (1,073,741,824 bytes)

As you might notice, the capacity of dual-layer discs is slightly less than twice of single-layer discs, even though the layers take up the same space on the discs (the spiral tracks are the same length). This was done intentionally to improve the readability of both layers in a dual-layer configuration. To do this, the bit cell spacing was slightly increased, which increases the length of each pit and land. When reading a dual-layer disc, the drive spins slightly faster to compensate, resulting in the same data rate. However, because the distance on the track is covered more quickly, less overall data can be stored.

Besides the standard four capacities listed here, a double-sided disc with one layer on one side and two layers on the other can also be produced. This would be called a DVD-14 and have a capacity of 13.2GB, or about 6 hours and 15 minutes of MPEG-2 video. Additionally, 80mm discs, which store less data in each configuration than the standard 120mm discs, can be produced.

Because of the manufacturing difficulties and the extra expense of double-sided discs—and the fact that they must be ejected and flipped to play both sides—most DVDs are configured as either a DVD-5 (single-sided, single-layer) or a DVD-9 (single-sided, dual-layer), which allows up to 8.5GB of data or 242 minutes of uninterrupted MPEG-2 video to be played. The 133-minute capacity of DVD-5 video discs accomodates 95% or more of the movies ever made.

Data Encoding on the Disc

As with CDs, the pits and lands themselves do not determine the bits; instead, the transitions (changes in reflectivity) from pit to land and land to pit are what determines the actual bits on the disc. The disc track is divided into bit cells or time intervals (T), and a pit or land used to represent data is required to be a minimum of 3T or a maximum of 11T intervals (cells) long. A 3T-long pit or land represents a 1001, and a 11T long pit or land represents a 100000000001.

Data is stored using 8 to 16 modulation, which is a modified version of the 8 to 14 modulation (EFM) used on CDs. Because of this, 8 to 16 modulation is sometimes called EFM+. This modulation takes each byte (8 bits) and converts it into a 16-bit value for storage. The 16-bit conversion codes are designed so that there are never less than 2 or more than 10 adjacent 0 bits (resulting in no less than 3 or no more than 11 time intervals between 1s). EFM+ is a form of RLL encoding called RLL 2,10 (RLL x,y where x = the minimum and y = the maximum run of 0s). This is designed to prevent long strings of 0s, which could more easily be misread due to clocks becoming out of sync, as well as to limit the minimum and maximum frequency of transitions actually placed on the recording media. Unlike CDs, no merge bits exist between codes. The 16-bit modulation codes are designed so that they will not violate the RLL 2,10 form without needing merge bits. Because the EFM used on CDs really requires more than 17 bits for each byte (because of the added merge and sync bits), EFM+ is slightly more efficient since only slightly more than 16 bits are generated for each byte encoded.

Note that although no more than 10 0s are allowed in the modulation generated by EFM+, the sync bits added when physical sectors are written can have up to 13 0s, meaning a time period of up to 14T between 1s written on the disc and pits or lands up to 14T intervals or bit cells in length.

DVD Drive Speed

As with CDs, DVDs rotate counterclockwise (as viewed from the reading laser) and typically are recorded at a constant data ratecalled CLV. This means that the track (and thus the data) is always moving past the read laser at the same speed, which originally was defined as 3.49 meters per second (or 3.84m/sec on dual-layer discs). Because the track is a spiral that is wound more tightly near the center of the disc, the disc must spin at varying rates to maintain the same track linear speed. In other words, to maintain a CLV, the disk must spin more quickly when reading the inner track area and more slowly when reading the outer track area. The speed of rotation in a 1x drive (3.49 meters per second is considered 1x speed) varies from 1,515rpm when reading the start (inner part) of the track down to 570rpm when reading the end (outer part) of the track.

Single-speed (1x) DVD-ROM drives provide a data transfer rate of 1.385MB/second, which means the data transfer rate from a DVD-ROM at 1x speed is roughly equivalent to a 9x CD-ROM (1x CD-ROM data transfer rate is 153.6KB/s, or 0.1536MB/s). This does not mean, however, that a 1x DVD drive can read CDs at 9x rates: DVD drives actually spin at a rate that is just under three times faster than a CD-ROM drive of the same speed. So, a 1x DVD drive spins at about the same rotational speed as a

Table 13.20 DVD Speeds and Transfer Rates

Column 1	Column 2	Column 3	Column 4	Column 5	Column 6	Column 7
Advertised DVD-ROM Speed (Max. if CAV)	**Time to Read Single Layer DVD if CLV**	**Time to Read Dual Layer DVD if CLV**	**Transfer Rate (Bytes/sec) (Max. if CAV)**	**Actual DVD Speed Minimum if CAV**	**Minimum Transfer Rate if CAV (Bytes/sec)**	**Average DVD Speed if CAV**

2.7x CD drive. Many DVD drives list two speeds, one for reading DVD discs and another for reading CD discs. For example, a DVD-ROM drive listed as a 16x/40x would indicate the performance when reading DVD/CD discs, respectively.

As with CDs, drive manufacturers began increasing the speeds of their drives by making them spin more quickly. A drive that spins twice as fast was called a 2x drive, drive that spins four times faster was 4x, and so on. At higher speeds, it became difficult to build motors that could change speeds (spin up or down) as quickly as needed when data was read from different parts of the disc. Because of this, most faster DVD drives spin the disc at a fixed rotational, rather than linear speed. This istermed *constant angular velocity (CAV)* because the angular velocity (or rotational speed) is what remains a constant.

The faster drives are useful primarily for data, not video. Having a faster drive can reduce or eliminate the pause during layer changes when playing a DVD video disc, but having a faster drive has no effect on video quality.

DVD-ROM drives have been available in speeds up to 20x or more, but because virtually all are CAV, they actually achieve the rated transfer speed only when reading the outer part of a disc. Table 13.20 shows the data rates for DVD drives reading DVD discs and how that rate compares to a CD-ROM drive.

Column 8	Column 9	Column 10	Column 11	Column 12	Column 13
Average Transfer Rate if CAV (Bytes/sec)	**Maximum Linear Speed (m/sec)**	**Maximum Linear Speed (mph)**	**Single Layer Rot. Speed Min. if CLV Max. if CAV (rpm)**	**Single Layer Rot. Speed Max. if CLV (rpm)**	**Usual Transfer Rate When Reading CD-ROMs**
969,231	3.5	7.8	570	1,515	2.7x
1,938,462	7.0	15.6	1,139	3,030	5.4x
3,946,154	14.0	31.2	2,279	6,059	11x
5,884,615	20.9	46.8	3,418	9,089	16x
7,823,077	27.9	62.5	4,558	12,119	21x
9,761,538	34.9	78.1	5,697	15,149	27x
11,769,231	41.9	93.7	6,836	18,178	32x
15,646,154	55.8	124.9	9,115	24,238	43x
19,592,308	69.8	156.1	11,394	30,297	54x
23,469,231	83.8	187.4	13,673	36,357	64x
31,292,308	111.7	249.8	18,230	48,476	86x

47,007,692	167.5	374.7	27,345	72,714	129x
48,946,154	174.5	390.3	28,485	75,743	134x

- *Column 1.* Indicates the advertised drive speed. This is a constant speed if the drive is CLV or a maximum speed only if CAV (most DVD-ROM drives are CAV).
- *Columns 2 and 3.* Indicate how long it would take to read a full disc (single- or dual-layer) if the drive were CLV. For CAV drives, those figures are longer because the average read speed is less than the advertised speed. The fourth column indicates the data transfer rate, which for CAV drives is a maximum figure seen only when reading the end of a disc.
- *Columns 4–8.* Indicate the actual minimum "x" speed for CAV drives, along with the minimum transfer speed (when reading the start of any disc) and an optimistic average speed (true only when reading a full disc; otherwise, it's even lower) in both "x" and byte-per-second formats.
- *Columns 9 and 10.* Indicate the maximum linear speeds the drive attains, in both meters per second and miles per hour. CLV drives maintain those speeds everywhere on the disc, whereas CAV drives reach those speeds only on the outer part of a disc.
- *Columns 11 and 12.* Indicate the rotational speeds of a drive. The first of those shows how quickly the disc spins when reading the start of a disc. This applies to either CAV or CLV drives. For CAV drives, that figure is constant no matter where on the disc is being read. The second of those two colums shows the maximum rotational speed if the drive were a CLV type. Because most faster drives are CAV, those figures are mostly theoretical for the faster drives.
- *Column 13.* Shows the speed the drive would be rated if it were a CD-ROM drive. This is based on the rotational speed, not the transfer rate. In other words, a 12x DVD drive would perform as a 32x CD-ROM drive when reading CDs. Most DVD drives list their speeds when reading CDs in the specifications. Due to the use of PCAV (Partial CAV) designs, some might have higher CD performances than the table indicates.

DVD Formats and Standards

As with the CD standards, the DVD standards are published in reference books produced mainly by the DVD forum, but also by other companies.

The DVD-Video and DVD-ROM standards are pretty well established, but recordable DVD technology is still evolving. The standards situation for recordable DVD is more confusing than usual, especially because there are at least four different (and somewhat incompatible) recording formats! It remains to be seen which will have the best support and become the most popular, but so far the DVD+RW format looks to be the most promising.

The current standard DVD formats are shown in Table 13.21.

Table 13.21 Standard DVD Formats and Capacities

Format	Disc Size	Sides	Layers	Data Capacity	Video Capacity
		DVD-ROM Formats and Capacities			
DVD-5	120mm	Single	Single	4.7GB	2.2 hours
DVD-9	120mm	Single	Double	8.5GB	4.0 hours
DVD-10	120mm	Double	Single	9.4GB	4.4 hours
DVD-14	120mm	Double	Both	13.2GB	6.3 hours
DVD-18	120mm	Double	Double	17.1GB	8.1 hours
DVD-1	80mm	Single	Single	1.5GB	0.7 hours
DVD-2	80mm	Single	Double	2.7GB	1.3 hours

Table 13.21 Continued

Format	Disc Size	Sides	Layers	Data Capacity	Video Capacity
DVD-3	80mm	Double	Single	2.9GB	1.4 hours
DVD-4	80mm	Double	Double	5.3GB	2.5 hours
Recordable DVD Formats and Capacities					
DVD-R 1.0	120mm	Single	Single	3.95GB	N/A
DVD-R 2.0	120mm	Single	Single	4.7GB	N/A
DVD-RAM 1.0	120mm	Single	Single	2.58GB	N/A
DVD-RAM 1.0	120mm	Double	Single	5.16GB	N/A
DVD-RAM 2.0	120mm	Single	Single	4.7GB	N/A
DVD-RAM 2.0	120mm	Double	Single	9.4GB	N/A
DVD-RAM 2.0	80mm	Single	Single	1.46GB	N/A
DVD-RAM 2.0	80mm	Double	Single	2.65GB	N/A
DVD-RW 2.0	120mm	Single	Single	4.7GB	N/A
DVD+RW 2.0	120mm	Single	Single	4.7GB	N/A
DVD+RW 2.0	120mm	Double	Single	9.4GB	N/A
CD-ROM Formats and Capacities (for comparison)					
CD-ROM/R/RW	120mm	Single	Single	0.737GB	N/A
CD-ROM/R/RW	80mm	Single	Single	0.194GB	N/A

With advancements coming in blue-light lasers, this capacity will be increased several-fold in the future with a HD-DVD format that can store up to 20GB per layer. Prototype players have already been shown by major manufacturers, although you shouldn't expect to see HD-DVD on the market for several years yet.
